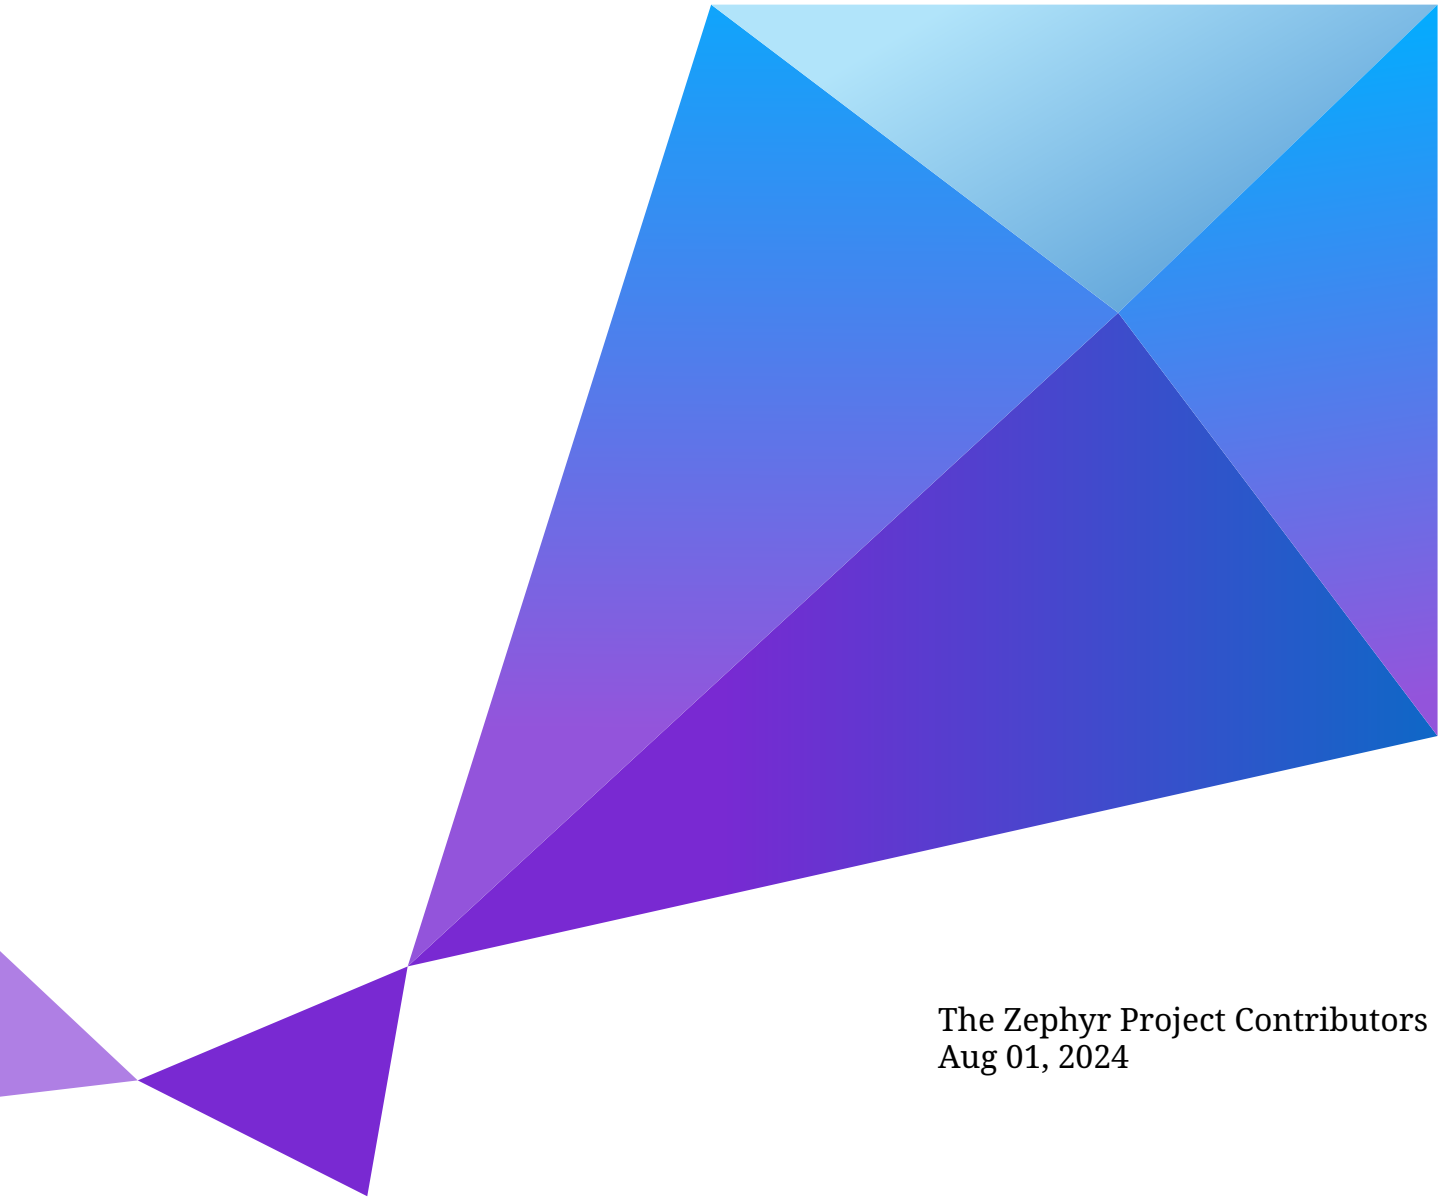
Zephyr Project Documentation

Release 3.7.99



The Zephyr Project Contributors

Aug 01, 2024

Table of contents

1 Introduction **1**
- 1.1 Licensing . . . 1
- 1.2 Distinguishing Features . . . 1
- 1.3 Community Support . . . 4
- 1.4 Resources . . . 4
  - 1.4.1 Getting Started . . . 4
  - 1.4.2 Code and Development . . . 4
  - 1.4.3 Community and Support . . . 4
  - 1.4.4 Issue Tracking and Security . . . 4
  - 1.4.5 Additional Resources . . . 4
- 1.5 Fundamental Terms and Concepts . . . 4

2 Developing with Zephyr **5**
- 2.1 Getting Started Guide . . . 5
  - 2.1.1 Select and Update OS . . . 5
  - 2.1.2 Install dependencies . . . 5
  - 2.1.3 Get Zephyr and install Python dependencies . . . 7
  - 2.1.4 Install the Zephyr SDK . . . 11
  - 2.1.5 Build the Blinky Sample . . . 13
  - 2.1.6 Flash the Sample . . . 14
  - 2.1.7 Next Steps . . . 14
  - 2.1.8 Troubleshooting Installation . . . 14
  - 2.1.9 Asking for Help . . . 15
- 2.2 Beyond the Getting Started Guide . . . 16
  - 2.2.1 Python and pip . . . 16
  - 2.2.2 Advanced Platform Setup . . . 16
  - 2.2.3 Install a Toolchain . . . 21
  - 2.2.4 Updating the Zephyr SDK toolchain . . . 22
  - 2.2.5 Cloning the Zephyr Repositories . . . 22
  - 2.2.6 Export Zephyr CMake package . . . 23
  - 2.2.7 Board Aliases . . . 23
  - 2.2.8 Build and Run an Application . . . 23
- 2.3 Environment Variables . . . 25
  - 2.3.1 Setting Variables . . . 25
  - 2.3.2 Zephyr Environment Scripts . . . 27
  - 2.3.3 Important Environment Variables . . . 27
- 2.4 Application Development . . . 28
  - 2.4.1 Overview . . . 28
  - 2.4.2 Application types . . . 30
  - 2.4.3 Creating an Application . . . 31
  - 2.4.4 Important Build System Variables . . . 33
  - 2.4.5 Application CMakeLists.txt . . . 34
  - 2.4.6 CMakeCache.txt . . . 36
  - 2.4.7 Application Configuration . . . 36
  - 2.4.8 Application-Specific Code . . . 38
  - 2.4.9 Building an Application . . . 39

2.4.10 Run an Application . . . 42
2.4.11 Custom Board, Devicetree and SOC Definitions . . . 43
2.5 Debugging . . . 47
2.5.1 Application Debugging . . . 47
2.5.2 Debug with Eclipse . . . 49
2.5.3 Debugging I2C communication . . . 51
2.6 API Status and Guidelines . . . 52
2.6.1 API Overview . . . 52
2.6.2 API Lifecycle . . . 65
2.6.3 API Design Guidelines . . . 69
2.6.4 API Terminology . . . 71
2.7 Language Support . . . 73
2.7.1 C Language Support . . . 73
2.7.2 C++ Language Support . . . 84
2.8 Optimizations . . . 88
2.8.1 Optimizing for Footprint . . . 88
2.8.2 Optimization Tools . . . 89
2.9 Flashing and Hardware Debugging . . . 93
2.9.1 Flash & Debug Host Tools . . . 93
2.9.2 Debug Probes . . . 100
2.10 Modules (External projects) . . . 106
2.10.1 Modules vs west projects . . . 107
2.10.2 Module Repositories . . . 107
2.10.3 Contributing to Zephyr modules . . . 109
2.10.4 Licensing requirements and policies . . . 110
2.10.5 Documentation requirements . . . 111
2.10.6 Testing requirements . . . 111
2.10.7 Deprecating and removing modules . . . 112
2.10.8 Integrate modules in Zephyr build system . . . 112
2.10.9 Module yaml file description . . . 113
2.10.10 Submitting changes to modules . . . 121
2.11 West (Zephyr's meta-tool) . . . 122
2.11.1 Installing west . . . 123
2.11.2 West Release Notes . . . 124
2.11.3 Troubleshooting West . . . 136
2.11.4 Basics . . . 139
2.11.5 Built-in commands . . . 142
2.11.6 Workspaces . . . 145
2.11.7 West Manifests . . . 150
2.11.8 Configuration . . . 179
2.11.9 Extensions . . . 182
2.11.10 Building, Flashing and Debugging . . . 185
2.11.11 Signing Binaries . . . 201
2.11.12 Additional Zephyr extension commands . . . 204
2.11.13 History and Motivation . . . 207
2.11.14 Moving to West . . . 209
2.11.15 Using Zephyr without west . . . 209
2.12 Testing . . . 211
2.12.1 Test Framework . . . 211
2.12.2 Test Runner (Twister) . . . 240
2.12.3 Twister blackbox tests . . . 261
2.12.4 Integration with pytest test framework . . . 264
2.12.5 Generating coverage reports . . . 270
2.12.6 BabbleSim . . . 272
2.12.7 ZTest Deprecated APIs . . . 275
2.13 Static Code Analysis (SCA) . . . 281
2.13.1 SCA Tool infrastructure . . . 281
2.13.2 Native SCA Tool support . . . 282

2.14 Toolchains . . . 284
2.14.1 Zephyr SDK . . . 284
2.14.2 Arm Compiler 6 . . . 288
2.14.3 Cadence Tensilica Xtensa C/C++ Compiler (XCC) . . . 288
2.14.4 DesignWare ARC MetaWare Development Toolkit (MWDT) . . . 289
2.14.5 GNU Arm Embedded . . . 290
2.14.6 Intel oneAPI Toolkit . . . 291
2.14.7 Crosstool-NG (Deprecated) . . . 291
2.14.8 Host Toolchains . . . 292
2.14.9 Other Cross Compilers . . . 292
2.14.10 Custom CMake Toolchains . . . 293
2.15 Tools and IDEs . . . 294
2.15.1 CLion . . . 294
2.15.2 Coccinelle . . . 299
2.15.3 Visual Studio Code . . . 307

3 Kernel **309**
3.1 Kernel Services . . . 309
3.1.1 Scheduling, Interrupts, and Synchronization . . . 309
3.1.2 Data Passing . . . 428
3.1.3 Memory Management . . . 471
3.1.4 Timing . . . 471
3.1.5 Other . . . 492
3.2 Device Driver Model . . . 513
3.2.1 Introduction . . . 513
3.2.2 Standard Drivers . . . 514
3.2.3 Synchronous Calls . . . 514
3.2.4 Driver APIs . . . 514
3.2.5 Driver Data Structures . . . 514
3.2.6 Subsystems and API Structures . . . 515
3.2.7 Device-Specific API Extensions . . . 516
3.2.8 Single Driver, Multiple Instances . . . 517
3.2.9 Initialization Levels . . . 518
3.2.10 Deferred initialization . . . 519
3.2.11 System Drivers . . . 519
3.2.12 Inspecting the initialization sequence . . . 519
3.2.13 Error handling . . . 519
3.2.14 Memory Mapping . . . 520
3.2.15 API Reference . . . 523
3.3 User Mode . . . 533
3.3.1 Overview . . . 533
3.3.2 Memory Protection Design . . . 535
3.3.3 Kernel Objects . . . 544
3.3.4 System Calls . . . 551
3.3.5 MPU Stack Objects . . . 560
3.3.6 MPU Backed Userspace . . . 561
3.4 Memory Management . . . 561
3.4.1 Memory Heaps . . . 561
3.4.2 Shared Multi Heap . . . 578
3.4.3 Memory Slabs . . . 582
3.4.4 Memory Blocks Allocator . . . 587
3.4.5 Demand Paging . . . 595
3.4.6 Virtual Memory . . . 603
3.5 Data Structures . . . 608
3.5.1 Single-linked List . . . 608
3.5.2 Double-linked List . . . 621
3.5.3 Multi Producer Single Consumer Packet Buffer . . . 629
3.5.4 Single Producer Single Consumer Packet Buffer . . . 631

3.5.5 Balanced Red/Black Tree . . . 632
3.5.6 Ring Buffers . . . 636
3.5.7 Multi Producer Single Consumer Lock Free Queue . . . 649
3.5.8 Single Producer Single Consumer Lock Free Queue . . . 650
3.6 Executing Time Functions . . . 652
3.6.1 Configuration . . . 652
3.6.2 Usage . . . 653
3.6.3 API documentation . . . 653
3.7 Object Cores . . . 663
3.7.1 Object Core Concepts . . . 664
3.7.2 Object Core Statistics Concepts . . . 664
3.7.3 Implementation . . . 665
3.7.4 Configuration Options . . . 667
3.7.5 API Reference . . . 667
3.8 Time Utilities . . . 673
3.8.1 Overview . . . 673
3.8.2 Time Utility APIs . . . 674
3.8.3 Concepts Underlying Time Support in Zephyr . . . 679
3.9 Utilities . . . 681
3.10 Iterable Sections . . . 701
3.10.1 Usage . . . 701
3.10.2 API Reference . . . 702
3.11 Code And Data Relocation . . . 707
3.11.1 Overview . . . 707
3.11.2 Details . . . 708

4 OS Services 711
4.1 Binary Descriptors . . . 711
4.1.1 Internals . . . 711
4.1.2 Usage . . . 712
4.1.3 API Reference . . . 713
4.2 Console . . . 715
4.3 Cryptography . . . 716
4.3.1 PSA Crypto . . . 716
4.3.2 Random Number Generation . . . 719
4.3.3 Crypto APIs . . . 722
4.4 Debugging . . . 729
4.4.1 Thread analyzer . . . 729
4.4.2 Core Dump . . . 731
4.4.3 GDB stub . . . 739
4.4.4 Cortex-M Debug Monitor . . . 744
4.4.5 MIPI STP Decoder . . . 745
4.4.6 Symbol Table (Symtab) . . . 748
4.5 Device Management . . . 749
4.5.1 MCUmgr . . . 749
4.5.2 MCUmgr handlers . . . 757
4.5.3 MCUmgr Callbacks . . . 765
4.5.4 Fixing and backporting fixes to Zephyr v2.7 MCUmgr . . . 775
4.5.5 SMP Protocol Specification . . . 778
4.5.6 SMP Transport Specification . . . 816
4.5.7 Device Firmware Upgrade . . . 821
4.5.8 Over-the-Air Update . . . 827
4.5.9 EC Host Command . . . 828
4.5.10 SMP Groups . . . 841
4.6 Digital Signal Processing (DSP) . . . 842
4.6.1 Using zDSP . . . 842
4.6.2 Optimizing for your architecture . . . 843
4.6.3 API Reference . . . 843

4.7 File Systems . . . 844
4.7.1 Samples . . . 844
4.7.2 API Reference . . . 845
4.8 Formatted Output . . . 861
4.8.1 Cbprintf Packaging . . . 862
4.8.2 API Reference . . . 864
4.9 Input . . . 874
4.9.1 Input Events . . . 874
4.9.2 Input Devices . . . 875
4.9.3 Application API . . . 875
4.9.4 HID code mapping . . . 875
4.9.5 Kscan Compatibility . . . 875
4.9.6 General Purpose Drivers . . . 875
4.9.7 Detailed Driver Documentation . . . 876
4.9.8 API Reference . . . 884
4.9.9 Input Event Definitions . . . 887
4.9.10 Analog Axis API Reference . . . 901
4.10 Interprocessor Communication (IPC) . . . 903
4.10.1 IPC service . . . 903
4.11 Linkable Loadable Extensions (LLEXT) . . . 919
4.11.1 Configuration . . . 919
4.11.2 Building extensions . . . 922
4.11.3 Loading extensions . . . 924
4.11.4 Troubleshooting . . . 925
4.11.5 API Reference . . . 926
4.12 Logging . . . 933
4.12.1 Global Kconfig Options . . . 935
4.12.2 Usage . . . 936
4.12.3 Logging panic . . . 938
4.12.4 Printk . . . 939
4.12.5 Architecture . . . 939
4.12.6 Recommendations . . . 945
4.12.7 Benchmark . . . 945
4.12.8 Stack usage . . . 946
4.12.9 API Reference . . . 946
4.13 Tracing . . . 967
4.13.1 Overview . . . 967
4.13.2 Serialization Formats . . . 968
4.13.3 Transport Backends . . . 970
4.13.4 Using Tracing . . . 970
4.13.5 Visualisation Tools . . . 971
4.13.6 Future LTTng Inspiration . . . 971
4.13.7 Object tracking . . . 972
4.13.8 API . . . 973
4.14 Resource Management . . . 1003
4.14.1 On-Off Manager . . . 1003
4.15 Memory Attributes . . . 1013
4.15.1 Migration guide from *zephyr,memory-region-mpu* . . . 1014
4.15.2 Memory Attributes Heap Allocator . . . 1014
4.15.3 API Reference . . . 1016
4.16 Modbus . . . 1019
4.16.1 Samples . . . 1019
4.16.2 API Reference . . . 1019
4.17 Modem modules . . . 1030
4.17.1 Modem pipe . . . 1030
4.17.2 Modem PPP . . . 1033
4.17.3 Modem CMUX . . . 1034
4.17.4 Modem pipelink . . . 1037

4.18 Asynchronous Notifications . . . 1040
4.18.1 API Reference . . . 1040
4.19 Power Management . . . 1043
4.19.1 Overview . . . 1043
4.19.2 System Power Management . . . 1044
4.19.3 Device Power Management . . . 1046
4.19.4 Device Runtime Power Management . . . 1052
4.19.5 Power Domain . . . 1057
4.19.6 Power Management APIs . . . 1060
4.20 OS Abstraction . . . 1084
4.20.1 POSIX . . . 1084
4.20.2 CMSIS RTOS v1 . . . 1112
4.20.3 CMSIS RTOS v2 . . . 1112
4.21 Power off . . . 1113
4.22 Shell . . . 1113
4.22.1 Overview . . . 1114
4.22.2 Backends . . . 1115
4.22.3 Commands . . . 1116
4.22.4 Tab Feature . . . 1123
4.22.5 History Feature . . . 1123
4.22.6 Wildcards Feature . . . 1124
4.22.7 Meta Keys Feature . . . 1124
4.22.8 Getopt Feature . . . 1125
4.22.9 Obscured Input Feature . . . 1125
4.22.10 Shell Logger Backend Feature . . . 1126
4.22.11 RTT Backend Channel Selection . . . 1126
4.22.12 Usage . . . 1126
4.22.13 API Reference . . . 1128
4.23 Serialization . . . 1149
4.23.1 Nanopb . . . 1149
4.24 Settings . . . 1150
4.24.1 Handlers . . . 1150
4.24.2 Backends . . . 1151
4.24.3 Zephyr Storage Backends . . . 1151
4.24.4 Storage Location . . . 1151
4.24.5 Loading data from persisted storage . . . 1151
4.24.6 Storing data to persistent storage . . . 1152
4.24.7 Secure domain settings . . . 1152
4.24.8 Example: Device Configuration . . . 1152
4.24.9 Example: Persist Runtime State . . . 1153
4.24.10 Example: Custom Backend Implementation . . . 1154
4.24.11 API Reference . . . 1155
4.25 State Machine Framework . . . 1165
4.25.1 Overview . . . 1165
4.25.2 State Creation . . . 1165
4.25.3 State Machine Creation . . . 1165
4.25.4 State Machine Execution . . . 1166
4.25.5 Preventing Parent Run Actions . . . 1166
4.25.6 State Machine Termination . . . 1166
4.25.7 UML State Machines . . . 1167
4.25.8 State Machine Examples . . . 1167
4.25.9 API Reference . . . 1174
4.26 Storage . . . 1177
4.26.1 Non-Volatile Storage (NVS) . . . 1177
4.26.2 Disk Access . . . 1182
4.26.3 Flash map . . . 1189
4.26.4 Flash Circular Buffer (FCB) . . . 1196
4.26.5 Stream Flash . . . 1202

4.27 Sensing Subsystem . . . 1205
4.27.1 Overview . . . 1206
4.27.2 Configurability . . . 1207
4.27.3 Main Features . . . 1207
4.27.4 Major Flows . . . 1208
4.27.5 Sensor Types And Instance . . . 1209
4.27.6 Sensor Instance Handler . . . 1210
4.27.7 Sensor Sample Value . . . 1211
4.27.8 Device Tree Configuration . . . 1212
4.27.9 API Reference . . . 1212
4.28 Task Watchdog . . . 1222
4.28.1 Overview . . . 1222
4.28.2 Configuration Options . . . 1222
4.28.3 API Reference . . . 1222
4.29 Trusted Firmware-M . . . 1224
4.29.1 Trusted Firmware-M Overview . . . 1224
4.29.2 TF-M Requirements . . . 1228
4.29.3 TF-M Build System . . . 1229
4.29.4 Trusted Firmware-M Integration . . . 1232
4.29.5 Test Suites . . . 1233
4.30 Virtualization . . . 1234
4.30.1 Inter-VM Shared Memory . . . 1234
4.31 Retention System . . . 1237
4.31.1 Devicetree setup . . . 1237
4.31.2 Mutex protection . . . 1238
4.31.3 Boot mode . . . 1239
4.31.4 Retention system modules . . . 1239
4.31.5 API Reference . . . 1242
4.32 Real Time I/O (RTIO) . . . 1245
4.32.1 Problem . . . 1246
4.32.2 Inspiration, introducing io_uring . . . 1246
4.32.3 Submission Queue . . . 1246
4.32.4 Completion Queue . . . 1247
4.32.5 Executor . . . 1247
4.32.6 IO Device . . . 1247
4.32.7 Cancellation . . . 1247
4.32.8 Memory pools . . . 1247
4.32.9 When to Use . . . 1248
4.32.10 API Reference . . . 1249
4.33 Zephyr bus (zbus) . . . 1259
4.33.1 Concepts . . . 1260
4.33.2 Usage . . . 1268
4.33.3 Samples . . . 1274
4.33.4 Suggested Uses . . . 1275
4.33.5 Configuration Options . . . 1275
4.33.6 API Reference . . . 1276
4.34 Miscellaneous . . . 1290
4.34.1 Checksum APIs . . . 1290
4.34.2 Structured Data APIs . . . 1296

5 Build and Configuration Systems 1309
5.1 Build System (CMake) . . . 1309
5.1.1 Build and Configuration Phases . . . 1309
5.1.2 Supporting Scripts and Tools . . . 1315
5.2 Devicetree . . . 1319
5.2.1 Devicetree Guide . . . 1319
5.2.2 Devicetree Reference . . . 1380
5.3 Configuration System (Kconfig) . . . 1578

5.3.1 Interactive Kconfig interfaces . . . 1579
5.3.2 Setting Kconfig configuration values . . . 1583
5.3.3 Kconfig - Tips and Best Practices . . . 1588
5.3.4 Custom Kconfig Preprocessor Functions . . . 1603
5.3.5 Kconfig extensions . . . 1605
5.4 Snippets . . . 1607
5.4.1 Using Snippets . . . 1607
5.4.2 Built-in snippets . . . 1608
5.4.3 Writing Snippets . . . 1610
5.4.4 Snippets Design . . . 1614
5.5 Zephyr CMake Package . . . 1614
5.5.1 Zephyr CMake package export (west) . . . 1615
5.5.2 Zephyr CMake package export (without west) . . . 1615
5.5.3 Zephyr Base Environment Setting . . . 1615
5.5.4 Zephyr CMake Package Search Order . . . 1615
5.5.5 Zephyr CMake Package Version . . . 1616
5.5.6 Multiple Zephyr Installations (Zephyr workspace) . . . 1618
5.5.7 Zephyr Build Configuration CMake packages . . . 1618
5.5.8 Zephyr CMake package source code . . . 1620
5.6 Sysbuild (System build) . . . 1620
5.6.1 Definitions . . . 1621
5.6.2 Architectural Overview . . . 1621
5.6.3 Building with sysbuild . . . 1622
5.6.4 Configuration namespacing . . . 1623
5.6.5 Sysbuild flashing using `west flash` . . . 1624
5.6.6 Sysbuild debugging using `west debug` . . . 1624
5.6.7 Building a sample with MCUboot . . . 1625
5.6.8 Sysbuild Kconfig file . . . 1625
5.6.9 Sysbuild targets . . . 1626
5.6.10 Dedicated image build targets . . . 1626
5.6.11 Adding Zephyr applications to sysbuild . . . 1627
5.6.12 Adding non-Zephyr applications to sysbuild . . . 1631
5.6.13 Extending sysbuild . . . 1631
5.7 Application version management . . . 1631
5.7.1 VERSION file . . . 1631
5.7.2 Use in code . . . 1632
5.7.3 Use in Kconfig . . . 1633
5.7.4 Use in CMake . . . 1633
5.7.5 Use in MCUboot-supported applications . . . 1634
5.8 Flashing . . . 1634
5.8.1 Flashing configuration . . . 1634

6 Connectivity **1637**
6.1 Bluetooth . . . 1637
6.1.1 Supported features . . . 1637
6.1.2 Qualification . . . 1639
6.1.3 Stack Architecture . . . 1659

Chapter 1

Introduction

The Zephyr OS is based on a small-footprint kernel designed for use on resource-constrained and embedded systems: from simple embedded environmental sensors and LED wearables to sophisticated embedded controllers, smart watches, and IoT wireless applications.

The Zephyr kernel supports multiple architectures, including:

- ARCv2 (EM and HS) and ARCv3 (HS6X)
- ARMv6-M, ARMv7-M, and ARMv8-M (Cortex-M)
- ARMv7-A and ARMv8-A (Cortex-A, 32- and 64-bit)
- ARMv7-R, ARMv8-R (Cortex-R, 32- and 64-bit)
- Intel x86 (32- and 64-bit)
- MIPS (MIPS32 Release 1 specification)
- NIOS II Gen 2
- RISC-V (32- and 64-bit)
- SPARC V8
- Tensilica Xtensa

The full list of supported boards based on these architectures can be found here.

In the context of the Zephyr OS, a *subsystem* refers to a logically distinct part of the operating system that handles specific functionality or provides certain services. Subsystems can include components such as networking, file systems, device driver classes, power management, and communication protocols, among others. Each subsystem is designed to be modular and can be configured, customized, and extended to meet the requirements of different embedded applications.

1.1 Licensing

Zephyr is permissively licensed using the Apache 2.0 license (as found in the `LICENSE` file in the project's GitHub repo). There are some imported or reused components of the Zephyr project that use other licensing, as described in *Licensing of Zephyr Project components*.

1.2 Distinguishing Features

Zephyr offers a large and ever growing number of features including:

Extensive suite of Kernel services
Zephyr offers a number of familiar services for development:

- *Multi-threading Services* for cooperative, priority-based, non-preemptive, and preemptive threads with optional round robin time-slicing. Includes POSIX pthreads compatible API support.
- *Interrupt Services* for compile-time registration of interrupt handlers.
- *Memory Allocation Services* for dynamic allocation and freeing of fixed-size or variable-size memory blocks.
- *Inter-thread Synchronization Services* for binary semaphores, counting semaphores, and mutex semaphores.
- *Inter-thread Data Passing Services* for basic message queues, enhanced message queues, and byte streams.
- *Power Management Services* such as overarching, application or policy-defined, System Power Management and fine-grained, driver-defined, Device Power Management.

Multiple Scheduling Algorithms
Zephyr provides a comprehensive set of thread scheduling choices:

- Cooperative and Preemptive Scheduling
- Earliest Deadline First (EDF)
- Meta IRQ scheduling implementing "interrupt bottom half" or "tasklet" behavior
- Timeslicing: Enables time slicing between preemptible threads of equal priority
- Multiple queuing strategies:
  - Simple linked-list ready queue
  - Red/black tree ready queue
  - Traditional multi-queue ready queue

Highly configurable / Modular for flexibility
Allows an application to incorporate *only* the capabilities it needs as it needs them, and to specify their quantity and size.

Cross Architecture
Supports a wide variety of supported boards with different CPU architectures and developer tools. Contributions have added support for an increasing number of SoCs, platforms, and drivers.

Memory Protection
Implements configurable architecture-specific stack-overflow protection, kernel object and device driver permission tracking, and thread isolation with thread-level memory protection on x86, ARC, and ARM architectures, userspace, and memory domains.

For platforms without MMU/MPU and memory constrained devices, supports combining application-specific code with a custom kernel to create a monolithic image that gets loaded and executed on a system's hardware. Both the application code and kernel code execute in a single shared address space.

Compile-time resource definition
Allows system resources to be defined at compile-time, which reduces code size and increases performance for resource-limited systems.

Optimized Device Driver Model
Provides a consistent device model for configuring the drivers that are part of the platform/system and a consistent model for initializing all the drivers configured into the system and allows the reuse of drivers across platforms that have common devices/IP blocks.

Devicetree Support
Use of *devicetree* to describe hardware. Information from devicetree is used to create the application image.

Native Networking Stack supporting multiple protocols
Networking support is fully featured and optimized, including LwM2M and BSD sockets compatible support. OpenThread support (on Nordic chipsets) is also provided - a mesh network designed to securely and reliably connect hundreds of products around the home.

Bluetooth Low Energy 5.0 support
Bluetooth 5.0 compliant (ESR10) and Bluetooth Low Energy Controller support (LE Link Layer). Includes Bluetooth Mesh and a Bluetooth qualification-ready Bluetooth controller.

- Generic Access Profile (GAP) with all possible LE roles
- Generic Attribute Profile (GATT)
- Pairing support, including the Secure Connections feature from Bluetooth 4.2
- Clean HCI driver abstraction
- Raw HCI interface to run Zephyr as a Controller instead of a full Host stack
- Verified with multiple popular controllers
- Highly configurable

Mesh Support:

- Relay, Friend Node, Low-Power Node (LPN) and GATT Proxy features
- Both Provisioning bearers supported (PB-ADV & PB-GATT)
- Highly configurable, fitting in devices with at least 16k RAM

Native Linux, macOS, and Windows Development
A command-line CMake build environment runs on popular developer OS systems. A native port (native_sim) lets you build and run Zephyr as a native application on Linux, aiding development and testing.

Virtual File System Interface with ext2, FatFs, and LittleFS Support
ext2, LittleFS and FatFS support; FCB (Flash Circular Buffer) for memory constrained applications.

Powerful multi-backend logging Framework
Support for log filtering, object dumping, panic mode, multiple backends (memory, networking, filesystem, console, ...) and integration with the shell subsystem.

User friendly and full-featured Shell interface
A multi-instance shell subsystem with user-friendly features such as autocompletion, wildcards, coloring, metakeys (arrows, backspace, ctrl+u, etc.) and history. Support for static commands and dynamic sub-commands.

Settings on non-volatile storage
The settings subsystem gives modules a way to store persistent per-device configuration and runtime state. Settings items are stored as key-value pair strings.

Non-volatile storage (NVS)
NVS allows storage of binary blobs, strings, integers, longs, and any combination of these.

Native port
Native sim allows running Zephyr as a Linux application with support for various subsystems and networking.

1.3 Community Support

Community support is provided via mailing lists and Discord; see the Resources below for details.

1.4 Resources

Here's a quick summary of resources to help you find your way around:

1.4.1 Getting Started

- Zephyr Documentation
- Getting Started Guide
- Tips when asking for help
- Code samples

1.4.2 Code and Development

- Source Code Repository
- Releases
- Contribution Guide

1.4.3 Community and Support

- Discord Server for real-time community discussions
- User mailing list (users@lists.zephyrproject.org)
- Developer mailing list (devel@lists.zephyrproject.org)
- Other project mailing lists
- Project Wiki

1.4.4 Issue Tracking and Security

- GitHub Issues
- Security documentation
- Security Advisories Repository
- Report security vulnerabilities at vulnerabilities@zephyrproject.org

1.4.5 Additional Resources

- Zephyr Project Website
- Zephyr Tech Talks

1.5 Fundamental Terms and Concepts

See *Glossary of Terms*

Chapter 2

Developing with Zephyr

2.1 Getting Started Guide

Follow this guide to:

- Set up a command-line Zephyr development environment on Ubuntu, macOS, or Windows (instructions for other Linux distributions are discussed in *Install Linux Host Dependencies*)
- Get the source code
- Build, flash, and run a sample application

2.1.1 Select and Update OS

Click the operating system you are using.

Ubuntu

This guide covers Ubuntu version 20.04 LTS and later.

```
sudo apt update
sudo apt upgrade
```

macOS

On macOS Mojave or later, select *System Preferences* > *Software Update*. Click *Update Now* if necessary.

On other versions, see this Apple support topic.

Windows

Select *Start* > *Settings* > *Update & Security* > *Windows Update*. Click *Check for updates* and install any that are available.

2.1.2 Install dependencies

Next, you'll install some host dependencies using your package manager.

The current minimum required version for the main dependencies are:

Tool	Min. Version
CMake	3.20.5
Python	3.10
Devicetree compiler	1.4.6

Ubuntu

1. If using an Ubuntu version older than 22.04, it is necessary to add extra repositories to meet the minimum required versions for the main dependencies listed above. In that case, download, inspect and execute the Kitware archive script to add the Kitware APT repository to your sources list. A detailed explanation of `kitware-archive.sh` can be found here kitware third-party apt repository:

```
wget https://apt.kitware.com/kitware-archive.sh
sudo bash kitware-archive.sh
```

2. Use `apt` to install the required dependencies:

```
sudo apt install --no-install-recommends git cmake ninja-build gperf \
  ccache dfu-util device-tree-compiler wget \
  python3-dev python3-pip python3-setuptools python3-tk python3-wheel xz-utils file \
  make gcc gcc-multilib g++-multilib libsdl2-dev libmagic1
```

3. Verify the versions of the main dependencies installed on your system by entering:

```
cmake --version
python3 --version
dtc --version
```

   Check those against the versions in the table in the beginning of this section. Refer to the *Install Linux Host Dependencies* page for additional information on updating the dependencies manually.

macOS

1. Install Homebrew:

```
/bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/HEAD/
↪install.sh)"
```

2. After the Homebrew installation script completes, follow the on-screen instructions to add the Homebrew installation to the path.

   - On macOS running on Apple Silicon, this is achieved with:

```
(echo; echo 'eval "$(/opt/homebrew/bin/brew shellenv)"') >> ~/.zprofile
source ~/.zprofile
```

   - On macOS running on Intel, use the command for Apple Silicon, but replace `/opt/homebrew/` with `/usr/local/`.

3. Use `brew` to install the required dependencies:

```
brew install cmake ninja gperf python3 ccache qemu dtc libmagic wget openocd
```

4. Add the Homebrew Python folder to the path, in order to be able to execute `python` and `pip` as well `python3` and `pip3`.

```
(echo; echo 'export PATH="'$(brew --prefix)'/opt/python/libexec/bin:$PATH"')␣
↪>> ~/.zprofile
source ~/.zprofile
```

Windows

> **Note**
>
> Due to issues finding executables, the Zephyr Project doesn't currently support application flashing using the Windows Subsystem for Linux (WSL) (WSL).
>
> Therefore, we don't recommend using WSL when getting started.

These instructions must be run in a `cmd.exe` command prompt terminal window. In modern version of Windows (10 and later) it is recommended to install the Windows Terminal application from the Microsoft Store. The required commands differ on PowerShell.

These instructions rely on Chocolatey. If Chocolatey isn't an option, you can install dependencies from their respective websites and ensure the command line tools are on your *PATH environment variable*.

1. Install chocolatey.
2. Open a `cmd.exe` terminal window as **Administrator**. To do so, press the Windows key, type `cmd.exe`, right-click the *Command Prompt* search result, and choose *Run as Administrator*.
3. Disable global confirmation to avoid having to confirm the installation of individual programs:

   ```
   choco feature enable -n allowGlobalConfirmation
   ```

4. Use choco to install the required dependencies:

   ```
   choco install cmake --installargs 'ADD_CMAKE_TO_PATH=System'
   choco install ninja gperf python311 git dtc-msys2 wget 7zip
   ```

   > **Warning**
   >
   > As of November 2023, Python 3.12 is not recommended for Zephyr development on Windows, as some required Python dependencies may be difficult to install.

5. Close the terminal window.

2.1.3 Get Zephyr and install Python dependencies

Next, clone Zephyr and its *modules* into a new *west* workspace named `zephyrproject`. You'll also install Zephyr's additional Python dependencies.

> **Note**
>
> It is easy to run into Python package incompatibilities when installing dependencies at a system or user level. This situation can happen, for example, if working on multiple Zephyr versions or other projects using Python on the same machine.
>
> For this reason it is suggested to use Python virtual environments.

Ubuntu

Install within virtual environment

1. Use `apt` to install Python `venv` package:

```
sudo apt install python3-venv
```

2. Create a new virtual environment:

```
python3 -m venv ~/zephyrproject/.venv
```

3. Activate the virtual environment:

```
source ~/zephyrproject/.venv/bin/activate
```

Once activated your shell will be prefixed with `(.venv)`. The virtual environment can be deactivated at any time by running `deactivate`.

> **Note**
>
> Remember to activate the virtual environment every time you start working.

4. Install west:

```
pip install west
```

5. Get the Zephyr source code:

```
west init ~/zephyrproject
cd ~/zephyrproject
west update
```

6. Export a *Zephyr CMake package*. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

```
west zephyr-export
```

7. Zephyr's `scripts/requirements.txt` file declares additional Python dependencies. Install them with `pip`.

```
pip install -r ~/zephyrproject/zephyr/scripts/requirements.txt
```

Install globally

1. Install west, and make sure `~/.local/bin` is on your *PATH environment variable*:

```
pip3 install --user -U west
echo 'export PATH=~/.local/bin:"$PATH"' >> ~/.bashrc
source ~/.bashrc
```

2. Get the Zephyr source code:

```
west init ~/zephyrproject
cd ~/zephyrproject
west update
```

3. Export a *Zephyr CMake package*. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

```
west zephyr-export
```

4. Zephyr's `scripts/requirements.txt` file declares additional Python dependencies. Install them with `pip3`.

```
pip3 install --user -r ~/zephyrproject/zephyr/scripts/requirements.txt
```

macOS

Install within virtual environment

1. Create a new virtual environment:

   ```
   python3 -m venv ~/zephyrproject/.venv
   ```

2. Activate the virtual environment:

   ```
   source ~/zephyrproject/.venv/bin/activate
   ```

   Once activated your shell will be prefixed with `(.venv)`. The virtual environment can be deactivated at any time by running `deactivate`.

   Note

   Remember to activate the virtual environment every time you start working.

3. Install west:

   ```
   pip install west
   ```

4. Get the Zephyr source code:

   ```
   west init ~/zephyrproject
   cd ~/zephyrproject
   west update
   ```

5. Export a *Zephyr CMake package*. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   ```
   west zephyr-export
   ```

6. Zephyr's `scripts/requirements.txt` file declares additional Python dependencies. Install them with `pip`.

   ```
   pip install -r ~/zephyrproject/zephyr/scripts/requirements.txt
   ```

Install globally

1. Install west:

   ```
   pip3 install -U west
   ```

2. Get the Zephyr source code:

   ```
   west init ~/zephyrproject
   cd ~/zephyrproject
   west update
   ```

3. Export a *Zephyr CMake package*. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   ```
   west zephyr-export
   ```

4. Zephyr's `scripts/requirements.txt` file declares additional Python dependencies. Install them with `pip3`.

```
pip3 install -r ~/zephyrproject/zephyr/scripts/requirements.txt
```

Windows

Install within virtual environment

1. Open a `cmd.exe` terminal window **as a regular user**
2. Create a new virtual environment:

```
cd %HOMEPATH%
python -m venv zephyrproject\.venv
```

3. Activate the virtual environment:

```
zephyrproject\.venv\Scripts\activate.bat
```

Once activated your shell will be prefixed with `(.venv)`. The virtual environment can be deactivated at any time by running `deactivate`.

> **Note**
>
> Remember to activate the virtual environment every time you start working.

4. Install west:

```
pip install west
```

5. Get the Zephyr source code:

```
west init zephyrproject
cd zephyrproject
west update
```

6. Export a *Zephyr CMake package*. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

```
west zephyr-export
```

7. Zephyr's `scripts\requirements.txt` file declares additional Python dependencies. Install them with `pip`.

```
pip install -r %HOMEPATH%\zephyrproject\zephyr\scripts\requirements.txt
```

Install globally

1. Open a `cmd.exe` terminal window **as a regular user**
2. Install west:

```
pip3 install -U west
```

3. Get the Zephyr source code:

```
cd %HOMEPATH%
west init zephyrproject
cd zephyrproject
west update
```

4. Export a *Zephyr CMake package*. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

```
west zephyr-export
```

5. Zephyr's `scripts\requirements.txt` file declares additional Python dependencies. Install them with `pip3`.

```
pip3 install -r %HOMEPATH%\zephyrproject\zephyr\scripts\requirements.txt
```

2.1.4 Install the Zephyr SDK

The *Zephyr Software Development Kit (SDK)* contains toolchains for each of Zephyr's supported architectures, which include a compiler, assembler, linker and other programs required to build Zephyr applications.

It also contains additional host tools, such as custom QEMU and OpenOCD builds that are used to emulate, flash and debug Zephyr applications.

Note

You can change `0.16.8` to another version in the instructions below if needed; the Zephyr SDK Releases page contains all available SDK releases.

Note

If you want to uninstall the SDK, you may simply remove the directory where you installed it.

Ubuntu

1. Download and verify the Zephyr SDK bundle:

```
cd ~
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.8/
↪zephyr-sdk-0.16.8_linux-x86_64.tar.xz
wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.
↪16.8/sha256.sum | shasum --check --ignore-missing
```

   If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace `x86_64` with `aarch64` in order to download the 64-bit ARM Linux SDK.

2. Extract the Zephyr SDK bundle archive:

```
tar xvf zephyr-sdk-0.16.8_linux-x86_64.tar.xz
```

Note

It is recommended to extract the Zephyr SDK bundle at one of the following locations:

- `$HOME`
- `$HOME/.local`
- `$HOME/.local/opt`
- `$HOME/bin`
- `/opt`
- `/usr/local`

The Zephyr SDK bundle archive contains the zephyr-sdk-<version> directory and, when extracted under $HOME, the resulting installation path will be $HOME/zephyr-sdk-<version>.

3. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-0.16.8
./setup.sh
```

Note

You only need to run the setup script once after extracting the Zephyr SDK bundle.

You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

4. Install udev rules, which allow you to flash most Zephyr boards as a regular user:

```
sudo cp ~/zephyr-sdk-0.16.8/sysroots/x86_64-pokysdk-linux/usr/share/openocd/
↪contrib/60-openocd.rules /etc/udev/rules.d
sudo udevadm control --reload
```

macOS

1. Download and verify the Zephyr SDK bundle:

```
cd ~
curl -L -O https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.
↪16.8/zephyr-sdk-0.16.8_macos-x86_64.tar.xz
curl -L https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.
↪8/sha256.sum | shasum --check --ignore-missing
```

If your host architecture is 64-bit ARM (Apple Silicon), replace x86_64 with aarch64 in order to download the 64-bit ARM macOS SDK.

2. Extract the Zephyr SDK bundle archive:

```
tar xvf zephyr-sdk-0.16.8_macos-x86_64.tar.xz
```

Note

It is recommended to extract the Zephyr SDK bundle at one of the following locations:

- $HOME
- $HOME/.local
- $HOME/.local/opt
- $HOME/bin
- /opt
- /usr/local

The Zephyr SDK bundle archive contains the zephyr-sdk-<version> directory and, when extracted under $HOME, the resulting installation path will be $HOME/zephyr-sdk-<version>.

3. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-0.16.8
./setup.sh
```

> **Note**
>
> You only need to run the setup script once after extracting the Zephyr SDK bundle.
>
> You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

Windows

1. Open a `cmd.exe` terminal window **as a regular user**
2. Download the Zephyr SDK bundle:

   ```
   cd %HOMEPATH%
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.8/
   ↪zephyr-sdk-0.16.8_windows-x86_64.7z
   ```

3. Extract the Zephyr SDK bundle archive:

   ```
   7z x zephyr-sdk-0.16.8_windows-x86_64.7z
   ```

   > **Note**
   >
   > It is recommended to extract the Zephyr SDK bundle at one of the following locations:
   >
   > - `%HOMEPATH%`
   > - `%PROGRAMFILES%`
   >
   > The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `%HOMEPATH%`, the resulting installation path will be `%HOMEPATH%\zephyr-sdk-<version>`.

4. Run the Zephyr SDK bundle setup script:

   ```
   cd zephyr-sdk-0.16.8
   setup.cmd
   ```

   > **Note**
   >
   > You only need to run the setup script once after extracting the Zephyr SDK bundle.
   >
   > You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

2.1.5 Build the Blinky Sample

> **Note**
>
> blinky is compatible with most, but not all, boards. If your board does not meet Blinky's blinky-sample-requirements, then hello_world is a good alternative.
>
> If you are unsure what name west uses for your board, `west boards` can be used to obtain a list of all boards Zephyr supports.

Build the blinky with *west build*, changing `<your-board-name>` appropriately for your board:

Ubuntu

```
cd ~/zephyrproject/zephyr
west build -p always -b <your-board-name> samples/basic/blinky
```

macOS

```
cd ~/zephyrproject/zephyr
west build -p always -b <your-board-name> samples/basic/blinky
```

Windows

```
cd %HOMEPATH%\zephyrproject\zephyr
west build -p always -b <your-board-name> samples\basic\blinky
```

The `-p always` option forces a pristine build, and is recommended for new users. Users may also use the `-p auto` option, which will use heuristics to determine if a pristine build is required, such as when building another sample.

Note

A board may contain one or multiple SoCs, Also, each SoC may contain one or more CPU clusters. When building for such boards it is necessary to specify the SoC or CPU cluster for which the sample must be built. For example to build blinky for the cpuapp core on the nRF5340DK the board must be provided as: `nrf5340dk/nrf5340/cpuapp`. See also *Board terminology* for more details.

2.1.6 Flash the Sample

Connect your board, usually via USB, and turn it on if there's a power switch. If in doubt about what to do, check your board's page in boards.

Then flash the sample using *west flash*:

```
west flash
```

You may need to install additional *host tools* required by your board. The `west flash` command will print an error if any required dependencies are missing.

If you're using blinky, the LED will start to blink as shown in this figure:

2.1.7 Next Steps

Here are some next steps for exploring Zephyr:

- Try other samples-and-demos
- Learn about *Application Development* and the *west* tool
- Find out about west's *flashing and debugging* features, or more about *Flashing and Hardware Debugging* in general
- Check out *Beyond the Getting Started Guide* for additional setup alternatives and ideas
- Discover *Resources* for getting help from the Zephyr community

2.1.8 Troubleshooting Installation

Here are some tips for fixing some issues related to the installation process.

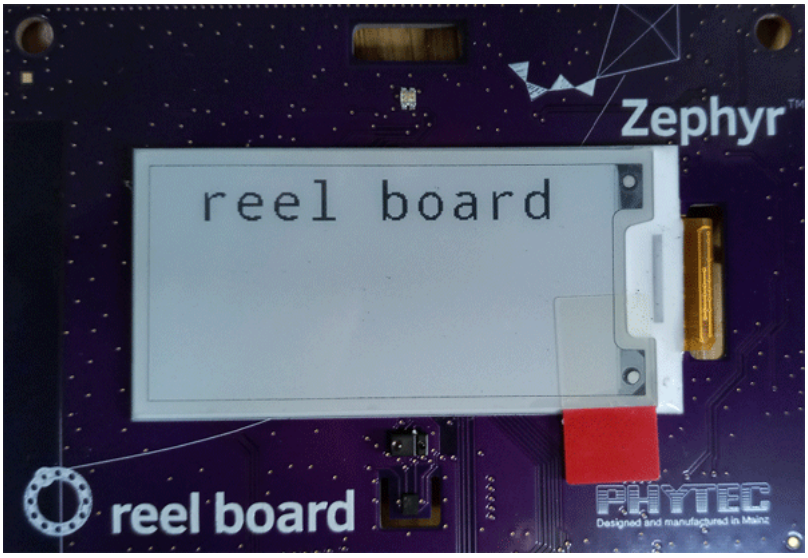

Fig. 1: Phytec reel_board running blinky

Double Check the Zephyr SDK Variables When Updating

When updating Zephyr SDK, check whether the *ZEPHYR_TOOLCHAIN_VARIANT* or *ZEPHYR_SDK_INSTALL_DIR* environment variables are already set. See *Updating the Zephyr SDK toolchain* for more information.

For more information about these environment variables in Zephyr, see *Important Environment Variables*.

2.1.9 Asking for Help

You can ask for help on a mailing list or on Discord. Please send bug reports and feature requests to GitHub.

- **Mailing Lists**: users@lists.zephyrproject.org is usually the right list to ask for help. Search archives and sign up here.
- **Discord**: You can join with this Discord invite.
- **GitHub**: Use GitHub issues for bugs and feature requests.

How to Ask

Important

Please search this documentation and the mailing list archives first. Your question may have an answer there.

Don't just say "this isn't working" or ask "is this working?". Include as much detail as you can about:

1. What you want to do
2. What you tried (commands you typed, etc.)
3. What happened (output of each command, etc.)

Use Copy/Paste

Please **copy/paste text** instead of taking a picture or a screenshot of it. Text includes source code, terminal commands, and their output.

Doing this makes it easier for people to help you, and also helps other users search the archives. Unnecessary screenshots exclude vision impaired developers; some are major Zephyr contributors. Accessibility has been recognized as a basic human right by the United Nations.

When copy/pasting more than 5 lines of computer text into Discord or Github, create a snippet using three backticks to delimit the snippet.

2.2 Beyond the Getting Started Guide

The *Getting Started Guide* gives a straight-forward path to set up your Linux, macOS, or Windows environment for Zephyr development. In this document, we delve deeper into Zephyr development setup issues and alternatives.

2.2.1 Python and pip

Python 3 and its package manager, pip[1], are used extensively by Zephyr to install and run scripts required to compile and run Zephyr applications, set up and maintain the Zephyr development environment, and build project documentation.

Depending on your operating system, you may need to provide the `--user` flag to the `pip3` command when installing new packages. This is documented throughout the instructions. See Installing Packages in the Python Packaging User Guide for more information about pip[1], including information on -\-user.

- On Linux, make sure `~/.local/bin` is at the front of your *PATH environment variable*, or programs installed with `--user` won't be found. Installing with `--user` avoids conflicts between pip and the system package manager, and is the default on Debian-based distributions.
- On macOS, Homebrew disables -\-user.
- On Windows, see the Installing Packages information on `--user` if you require using this option.

On all operating systems, pip's `-U` flag installs or updates the package if the package is already installed locally but a more recent version is available. It is good practice to use this flag if the latest version of a package is required. (Check the scripts/requirements.txt file to see if a specific Python package version is expected.)

2.2.2 Advanced Platform Setup

Here are some alternative instructions for more advanced platform setup configurations for supported development platforms:

[1] pip is Python's package installer. Its `install` command first tries to reuse packages and package dependencies already installed on your computer. If that is not possible, `pip install` downloads them from the Python Package Index (PyPI) on the Internet.
The package versions requested by Zephyr's `requirements.txt` may conflict with other requirements on your system, in which case you may want to set up a virtualenv for Zephyr development.

Install Linux Host Dependencies

Documentation is available for these Linux distributions:

- Ubuntu
- Fedora
- Clear Linux
- Arch Linux

For distributions that are not based on rolling releases, some of the requirements and dependencies may not be met by your package manager. In that case please follow the additional instructions that are provided to find software from sources other than the package manager.

> **Note**
>
> If you're working behind a corporate firewall, you'll likely need to configure a proxy for accessing the internet, if you haven't done so already. While some tools use the environment variables `http_proxy` and `https_proxy` to get their proxy settings, some use their own configuration files, most notably `apt` and `git`.

Update Your Operating System Ensure your host system is up to date.

Ubuntu

```
sudo apt-get update
sudo apt-get upgrade
```

Fedora

```
sudo dnf upgrade
```

Clear Linux

```
sudo swupd update
```

Arch Linux

```
sudo pacman -Syu
```

Install Requirements and Dependencies Note that both Ninja and Make are installed with these instructions; you only need one.

Ubuntu

```
sudo apt-get install --no-install-recommends git cmake ninja-build gperf \
  ccache dfu-util device-tree-compiler wget \
  python3-dev python3-pip python3-setuptools python3-tk python3-wheel xz-utils file \
  make gcc gcc-multilib g++-multilib libsdl2-dev libmagic1
```

Fedora

```
sudo dnf group install "Development Tools" "C Development Tools and Libraries"
sudo dnf install cmake ninja-build gperf dfu-util dtc wget which \
  python3-pip python3-tkinter xz file python3-devel SDL2-devel
```

Clear Linux

```
sudo swupd bundle-add c-basic dev-utils dfu-util dtc \
  os-core-dev python-basic python3-basic python3-tcl
```

The Clear Linux focus is on *native* performance and security and not cross-compilation. For that reason it uniquely exports by default to the *environment* of all users a list of compiler and linker flags. Zephyr's CMake build system will either warn or fail because of these. To clear the C/C++ flags among these and fix the Zephyr build, run the following command as root then log out and back in:

```
echo 'unset CFLAGS CXXFLAGS' >> /etc/profile.d/unset_cflags.sh
```

Note this command unsets the C/C++ flags for *all users on the system*. Each Linux distribution has a unique, relatively complex and potentially evolving sequence of bash initialization files sourcing each other and Clear Linux is no exception. If you need a more flexible solution, start by looking at the logic in `/usr/share/defaults/etc/profile`.

Arch Linux

```
sudo pacman -S git cmake ninja gperf ccache dfu-util dtc wget \
    python-pip python-setuptools python-wheel tk xz file make
```

CMake A *recent CMake version* is required. Check what version you have by using `cmake --version`. If you have an older version, there are several ways of obtaining a more recent one:

- On Ubuntu, you can follow the instructions for adding the kitware third-party apt repository to get an updated version of cmake using apt.
- Download and install a packaged cmake from the CMake project site. (Note this won't uninstall the previous version of cmake.)

  ```
  cd ~
  wget https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-Linux-x86_
  ↪64.sh
  chmod +x cmake-3.21.1-Linux-x86_64.sh
  sudo ./cmake-3.21.1-Linux-x86_64.sh --skip-license --prefix=/usr/local
  hash -r
  ```

  The `hash -r` command may be necessary if the installation script put cmake into a new location on your PATH.

- Download and install from the pre-built binaries provided by the CMake project itself in the CMake Downloads page. For example, to install version 3.21.1 in `~/bin/cmake`:

  ```
  mkdir $HOME/bin/cmake && cd $HOME/bin/cmake
  wget https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-Linux-x86_
  ↪64.sh
  yes | sh cmake-3.21.1-Linux-x86_64.sh | cat
  echo "export PATH=$PWD/cmake-3.21.1-Linux-x86_64/bin:\$PATH" >> $HOME/.zephyrrc
  ```

- Use `pip3`:

  ```
  pip3 install --user cmake
  ```

  Note this won't uninstall the previous version of cmake and will install the new cmake into your ~/.local/bin folder so you'll need to add ~/.local/bin to your PATH. (See *Python and pip* for details.)

- Check your distribution's beta or unstable release package library for an update.
- On Ubuntu you can also use snap to get the latest version available:

```
sudo snap install cmake
```

After updating cmake, verify that the newly installed cmake is found using `cmake --version`. You might also want to uninstall the CMake provided by your package manager to avoid conflicts. (Use `whereis cmake` to find other installed versions.)

DTC (Device Tree Compiler) A *recent DTC version* is required. Check what version you have by using `dtc --version`. If you have an older version, either install a more recent one by building from source, or use the one that is bundled in the *Zephyr SDK* by installing it.

Python A *modern Python 3 version* is required. Check what version you have by using `python3 --version`.

If you have an older version, you will need to install a more recent Python 3. You can build from source, or use a backport from your distribution's package manager channels if one is available. Isolating this Python in a virtual environment is recommended to avoid interfering with your system Python.

Install the Zephyr Software Development Kit (SDK) The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr's supported architectures. It also includes additional host tools, such as custom QEMU and OpenOCD.

Use of the Zephyr SDK is highly recommended and may even be required under certain conditions (for example, running tests in QEMU for some architectures).

The Zephyr SDK supports the following target architectures:

- ARC (32-bit and 64-bit; ARCv1, ARCv2, ARCv3)
- ARM (32-bit and 64-bit; ARMv6, ARMv7, ARMv8; A/R/M Profiles)
- MIPS (32-bit and 64-bit)
- Nios II
- RISC-V (32-bit and 64-bit; RV32I, RV32E, RV64I)
- x86 (32-bit and 64-bit)
- Xtensa

Follow these steps to install the Zephyr SDK:

1. Download and verify the Zephyr SDK bundle:

   ```
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.8/
   ↪zephyr-sdk-0.16.8_linux-x86_64.tar.xz
   wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.
   ↪16.8/sha256.sum | shasum --check --ignore-missing
   ```

   You can change `0.16.8` to another version if needed; the Zephyr SDK Releases page contains all available SDK releases.

   If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace `x86_64` with `aarch64` in order to download the 64-bit ARM Linux SDK.

2. Extract the Zephyr SDK bundle archive:

   ```
   cd <sdk download directory>
   tar xvf zephyr-sdk-0.16.8_linux-x86_64.tar.xz
   ```

3. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-0.16.8
./setup.sh
```

If this fails, make sure Zephyr's dependencies were installed as described in *Install Requirements and Dependencies*.

If you want to uninstall the SDK, remove the directory where you installed it. If you relocate the SDK directory, you need to re-run the setup script.

Note

It is recommended to extract the Zephyr SDK bundle at one of the following locations:

- `$HOME`
- `$HOME/.local`
- `$HOME/.local/opt`
- `$HOME/bin`
- `/opt`
- `/usr/local`

The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `$HOME`, the resulting installation path will be `$HOME/zephyr-sdk-<version>`.

If you install the Zephyr SDK outside any of these locations, you must register the Zephyr SDK in the CMake package registry by running the setup script, or set *ZEPHYR_SDK_INSTALL_DIR* to point to the Zephyr SDK installation directory.

You can also use *ZEPHYR_SDK_INSTALL_DIR* for pointing to a directory containing multiple Zephyr SDKs, allowing for automatic toolchain selection. For example, `ZEPHYR_SDK_INSTALL_DIR=/company/tools`, where the `company/tools` folder contains the following subfolders:

- `/company/tools/zephyr-sdk-0.13.2`
- `/company/tools/zephyr-sdk-a.b.c`
- `/company/tools/zephyr-sdk-x.y.z`

This allows the Zephyr build system to choose the correct version of the SDK, while allowing multiple Zephyr SDKs to be grouped together at a specific path.

Building on Linux without the Zephyr SDK The Zephyr SDK is provided for convenience and ease of use. It provides toolchains for all Zephyr target architectures, and does not require any extra flags when building applications or running tests. In addition to cross-compilers, the Zephyr SDK also provides prebuilt host tools. It is, however, possible to build without the SDK's toolchain by using another toolchain as described in the *Toolchains* section.

As already noted above, the SDK also includes prebuilt host tools. To use the SDK's prebuilt host tools with a toolchain from another source, you must set the *ZEPHYR_SDK_INSTALL_DIR* environment variable to the Zephyr SDK installation directory. To build without the Zephyr SDK's prebuilt host tools, the *ZEPHYR_SDK_INSTALL_DIR* environment variable must be unset.

To make sure this variable is unset, run:

```
unset ZEPHYR_SDK_INSTALL_DIR
```

macOS alternative setup instructions

Important note about Gatekeeper Starting with macOS 10.15 Catalina, applications launched from the macOS Terminal application (or any other terminal emulator) are subject to the same system security policies that are applied to applications launched from the Dock. This means that if you download executable binaries using a web browser, macOS will not let you execute those from the Terminal by default. In order to get around this issue you can take two different approaches:

- Run `xattr -r -d com.apple.quarantine /path/to/folder` where `path/to/folder` is the path to the enclosing folder where the executables you want to run are located.
- Open *System Preferences* ‣ *Security and Privacy* ‣ *Privacy* and then scroll down to "Developer Tools". Then unlock the lock to be able to make changes and check the checkbox corresponding to your terminal emulator of choice. This will apply to any executable being launched from such terminal program.

Note that this section does **not** apply to executables installed with Homebrew, since those are automatically un-quarantined by `brew` itself. This is however relevant for most *Toolchains*.

Additional notes for MacPorts users While MacPorts is not officially supported in this guide, it is possible to use MacPorts instead of Homebrew to get all the required dependencies on macOS. Note also that you may need to install `rust` and `cargo` for the Python dependencies to install correctly.

Windows alternative setup instructions

Windows 10 WSL (Windows Subsystem for Linux) If you are running a recent version of Windows 10 you can make use of the built-in functionality to natively run Ubuntu binaries directly on a standard command-prompt. This allows you to use software such as the *Zephyr SDK* without setting up a virtual machine.

Warning

Windows 10 version 1803 has an issue that will cause CMake to not work properly and is fixed in version 1809 (and later). More information can be found in Zephyr Issue 10420.

1. Install the Windows Subsystem for Linux (WSL).

   Note

   For the Zephyr SDK to function properly you will need Windows 10 build 15002 or greater. You can check which Windows 10 build you are running in the "About your PC" section of the System Settings. If you are running an older Windows 10 build you might need to install the Creator's Update.

2. Follow the Ubuntu instructions in the *Install Linux Host Dependencies* document.

2.2.3 Install a Toolchain

Zephyr binaries are compiled and linked by a *toolchain* comprised of a cross-compiler and related tools which are different from the compiler and tools used for developing software that runs natively on your host operating system.

You can install the *Zephyr SDK* to get toolchains for all supported architectures, or install an *alternate toolchain* recommended by the SoC vendor or a specific board (check your specific board-level documentation).

You can configure the Zephyr build system to use a specific toolchain by setting *environment variables* such as *ZEPHYR_TOOLCHAIN_VARIANT* to a supported value, along with additional variable(s) specific to the toolchain variant.

2.2.4 Updating the Zephyr SDK toolchain

When updating Zephyr SDK, check whether the *ZEPHYR_TOOLCHAIN_VARIANT* or *ZEPHYR_SDK_INSTALL_DIR* environment variables are already set.

- If the variables are not set, the latest compatible version of Zephyr SDK will be selected by default. Proceed to next step without making any changes.
- If *ZEPHYR_TOOLCHAIN_VARIANT* is set, the corresponding toolchain will be selected at build time. Zephyr SDK is identified by the value `zephyr`. If the *ZEPHYR_TOOLCHAIN_VARIANT* environment variable is not `zephyr`, then either unset it or change its value to `zephyr` to make sure Zephyr SDK is selected.
- If the *ZEPHYR_SDK_INSTALL_DIR* environment variable is set, it will override the default lookup location for Zephyr SDK. If you install Zephyr SDK to one of the *recommended locations*, you can unset this variable. Otherwise, set it to your chosen install location.

For more information about these environment variables in Zephyr, see *Important Environment Variables*.

2.2.5 Cloning the Zephyr Repositories

The Zephyr project source is maintained in the GitHub zephyr repo. External modules used by Zephyr are found in the parent GitHub Zephyr project. Because of these dependencies, it's convenient to use the Zephyr-created *west* tool to fetch and manage the Zephyr and external module source code. See *Basics* for more details.

Once your development tools are installed, use *West (Zephyr's meta-tool)* to create, initialize, and download sources from the zephyr and external module repos. We'll use the name `zephyrproject`, but you can choose any name that does not contain a space anywhere in the path.

```
west init zephyrproject
cd zephyrproject
west update
```

The `west update` command fetches and keeps *Modules (External projects)* in the `zephyrproject` folder in sync with the code in the local zephyr repo.

Warning

You must run `west update` any time the `zephyr/west.yml` changes, caused, for example, when you pull the `zephyr` repository, switch branches in it, or perform a `git bisect` inside of it.

Keeping Zephyr updated

To update the Zephyr project source code, you need to get the latest changes via `git`. Afterwards, run `west update` as mentioned in the previous paragraph.

```
# replace zephyrproject with the path you gave west init
cd zephyrproject/zephyr
git pull
west update
```

2.2.6 Export Zephyr CMake package

The *Zephyr CMake Package* can be exported to CMake's user package registry if it has not already been done as part of *Getting Started Guide*.

2.2.7 Board Aliases

Developers who work with multiple boards may find explicit board names cumbersome and want to use aliases for common targets. This is supported by a CMake file with content like this:

```
# Variable foo_BOARD_ALIAS=bar replaces BOARD=foo with BOARD=bar and
# sets BOARD_ALIAS=foo in the CMake cache.
set(pca10028_BOARD_ALIAS nrf51dk/nrf51822)
set(pca10056_BOARD_ALIAS nrf52840dk/nrf52840)
set(k64f_BOARD_ALIAS frdm_k64f)
set(sltb004a_BOARD_ALIAS efr32mg_sltb004a)
```

and specifying its location in *ZEPHYR_BOARD_ALIASES*. This enables use of aliases `pca10028` in contexts like `cmake -DBOARD=pca10028` and `west -b pca10028`.

2.2.8 Build and Run an Application

You can build, flash, and run Zephyr applications on real hardware using a supported host system. Depending on your operating system, you can also run it in emulation with QEMU, or as a native application with native_sim. Additional information about building applications can be found in the *Building an Application* section.

Build Blinky

Let's build the blinky sample application.

Zephyr applications are built to run on specific hardware, called a "board"[2]. We'll use the Phytec reel_board here, but you can change the `reel_board` build target to another value if you have a different board. See boards or run `west boards` from anywhere inside the `zephyrproject` directory for a list of supported boards.

1. Go to the zephyr repository:

   ```
   cd zephyrproject/zephyr
   ```

2. Build the blinky sample for the `reel_board`:

   ```
   west build -b reel_board samples/basic/blinky
   ```

[2] This has become something of a misnomer over time. While the target can be, and often is, a microprocessor running on its own dedicated hardware board, Zephyr also supports using QEMU to run targets built for other architectures in emulation, targets which produce native host system binaries that implement Zephyr's driver interfaces with POSIX APIs, and even running different Zephyr-based binaries on CPU cores of differing architectures on the same physical chip. Each of these hardware configurations is called a "board," even though that doesn't always make perfect sense in context.

The main build products will be in `build/zephyr`; `build/zephyr/zephyr.elf` is the blinky application binary in ELF format. Other binary formats, disassembly, and map files may be present depending on your board.

The other sample applications in the samples folder are documented in samples-and-demos.

Note

If you want to reuse an existing build directory for another board or application, you need to add the parameter `-p=auto` to `west build` to clean out settings and artifacts from the previous build.

Run the Application by Flashing to a Board

Most hardware boards supported by Zephyr can be flashed by running `west flash`. This may require board-specific tool installation and configuration to work properly.

See *Run an Application* and your specific board's documentation in boards for additional details.

Setting udev rules

Flashing a board requires permission to directly access the board hardware, usually managed by installation of the flashing tools. On Linux systems, if the `west flash` command fails, you likely need to define udev rules to grant the needed access permission.

Udev is a device manager for the Linux kernel and the udev daemon handles all user space events raised when a hardware device is added (or removed) from the system. We can add a rules file to grant access permission by non-root users to certain USB-connected devices.

The OpenOCD (On-Chip Debugger) project conveniently provides a rules file that defined board-specific rules for most Zephyr-supported arm-based boards, so we recommend installing this rules file by downloading it from their sourceforge repo, or if you've installed the Zephyr SDK there is a copy of this rules file in the SDK folder:

- Either download the OpenOCD rules file and copy it to the right location:

```
wget -O 60-openocd.rules https://sf.net/p/openocd/code/ci/master/tree/contrib/60-
↪openocd.rules?format=raw
sudo cp 60-openocd.rules /etc/udev/rules.d
```

- or copy the rules file from the Zephyr SDK folder:

```
sudo cp ${ZEPHYR_SDK_INSTALL_DIR}/sysroots/x86_64-pokysdk-linux/usr/share/openocd/
↪contrib/60-openocd.rules /etc/udev/rules.d
```

Then, in either case, ask the udev daemon to reload these rules:

```
sudo udevadm control --reload
```

Unplug and plug in the USB connection to your board, and you should have permission to access the board hardware for flashing. Check your board-specific documentation (boards) for further information if needed.

Run the Application in QEMU

On Linux and macOS, you can run Zephyr applications via emulation on your host system using QEMU when targeting either the x86 or ARM Cortex-M3 architectures. (QEMU is included with the Zephyr SDK installation.)

On Windows, you need to install QEMU manually from Download QEMU. After installation, add path to QEMU installation folder to PATH environment variable. To enable QEMU in Test Runner (Twister) on Windows, *set the environment variable* `QEMU_BIN_PATH` to the path of QEMU installation folder.

For example, you can build and run the hello_world sample using the x86 emulation board configuration (`qemu_x86`), with:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
west build -t run
```

To exit QEMU, type `Ctrl-a`, then `x`.

Use `qemu_cortex_m3` to target an emulated Arm Cortex-M3 sample.

Run a Sample Application natively (Linux)

You can compile some samples to run as host programs on Linux. See native_sim for more information. On 64-bit host operating systems, you need to install a 32-bit C library, or build targeting native_sim/native/64.

First, build Hello World for `native_sim`.

```
# From the root of the zephyr repository
west build -b native_sim samples/hello_world
```

Next, run the application.

```
west build -t run
# or just run zephyr.exe directly:
./build/zephyr/zephyr.exe
```

Press `Ctrl-C` to exit.

You can run `./build/zephyr/zephyr.exe --help` to get a list of available options.

This executable can be instrumented using standard tools, such as gdb or valgrind.

2.3 Environment Variables

Various pages in this documentation refer to setting Zephyr-specific environment variables. This page describes how.

2.3.1 Setting Variables

Option 1: Just Once

To set the environment variable `MY_VARIABLE` to `foo` for the lifetime of your current terminal window:

Linux/macOS

```
export MY_VARIABLE=foo
```

Windows

```
set MY_VARIABLE=foo
```

Warning

This is best for experimentation. If you close your terminal window, use another terminal window or tab, restart your computer, etc., this setting will be lost forever.

Using options 2 or 3 is recommended if you want to keep using the setting.

Option 2: In all Terminals

Linux/macOS

Add the `export MY_VARIABLE=foo` line to your shell's startup script in your home directory. For Bash, this is usually `~/.bashrc` on Linux or `~/.bash_profile` on macOS. Changes in these startup scripts don't affect shell instances already started; try opening a new terminal window to get the new settings.

Windows

You can use the `setx` program in `cmd.exe` or the third-party RapidEE program.

To use `setx`, type this command, then close the terminal window. Any new `cmd.exe` windows will have `MY_VARIABLE` set to `foo`.

```
setx MY_VARIABLE foo
```

To install RapidEE, a freeware graphical environment variable editor, using Chocolatey in an Administrator command prompt:

```
choco install rapidee
```

You can then run `rapidee` from your terminal to launch the program and set environment variables. Make sure to use the "User" environment variables area – otherwise, you have to run RapidEE as administrator. Also make sure to save your changes by clicking the Save button at top left before exiting. Settings you make in RapidEE will be available whenever you open a new terminal window.

Option 3: Using `zephyrrc` files

Choose this option if you don't want to make the variable's setting available to all of your terminals, but still want to save the value for loading into your environment when you are using Zephyr.

Linux/macOS

Create a file named `~/.zephyrrc` if it doesn't exist, then add this line to it:

```
export MY_VARIABLE=foo
```

To get this value back into your current terminal environment, **you must run** `source zephyr-env.sh` from the main `zephyr` repository. Among other things, this script sources `~/.zephyrrc`.

The value will be lost if you close the window, etc.; run `source zephyr-env.sh` again to get it back.

Windows

Add the line `set MY_VARIABLE=foo` to the file `%userprofile%\zephyrrc.cmd` using a text editor such as Notepad to save the value.

To get this value back into your current terminal environment, **you must run** `zephyr-env.cmd` in a `cmd.exe` window after changing directory to the main `zephyr` repository. Among other things, this script runs `%userprofile%\zephyrrc.cmd`.

The value will be lost if you close the window, etc.; run `zephyr-env.cmd` again to get it back.

These scripts:

- set *ZEPHYR_BASE* to the location of the zephyr repository
- adds some Zephyr-specific locations (such as zephyr's `scripts` directory) to your *PATH* environment variable
- loads any settings from the `zephyrrc` files described above in *Option 3: Using zephyrrc files*.

You can thus use them any time you need any of these settings.

2.3.2 Zephyr Environment Scripts

You can use the zephyr repository scripts `zephyr-env.sh` (for macOS and Linux) and `zephyr-env.cmd` (for Windows) to load Zephyr-specific settings into your current terminal's environment. To do so, run this command from the zephyr repository:

Linux/macOS

```
source zephyr-env.sh
```

Windows

```
zephyr-env.cmd
```

These scripts:

- set *ZEPHYR_BASE* to the location of the zephyr repository
- adds some Zephyr-specific locations (such as zephyr's `scripts` directory) to your `PATH` environment variable
- loads any settings from the `zephyrrc` files described above in *Option 3: Using zephyrrc files*.

You can thus use them any time you need any of these settings.

2.3.3 Important Environment Variables

Some *Important Build System Variables* can also be set in the environment. Here is a description of some of these important environment variables. This is not a comprehensive list.

`BOARD`
: See *Important Build System Variables*.

`CONF_FILE`
: See *Important Build System Variables*.

`SHIELD`
: See *Shields*.

`ZEPHYR_BASE`
: See *Important Build System Variables*.

`EXTRA_ZEPHYR_MODULES`
: See *Important Build System Variables*.

`ZEPHYR_MODULES`
: See *Important Build System Variables*.

`ZEPHYR_BOARD_ALIASES`
: See *Board Aliases*

The following additional environment variables are significant when configuring the *toolchain* used to build Zephyr applications.

`ZEPHYR_SDK_INSTALL_DIR`
: Path where Zephyr SDK is installed.

`ZEPHYR_TOOLCHAIN_VARIANT`
: The name of the toolchain to use.

`{TOOLCHAIN}_TOOLCHAIN_PATH`
: Path to the toolchain specified by *ZEPHYR_TOOLCHAIN_VARIANT*. For example, if `ZEPHYR_TOOLCHAIN_VARIANT=llvm`, use `LLVM_TOOLCHAIN_PATH`. (Note the capitalization when forming the environment variable name.)

You might need to update some of these variables when you *update the Zephyr SDK toolchain*.

Emulators and boards may also depend on additional programs. The build system will try to locate those programs automatically, but may rely on additional CMake or environment variables to do so. Please consult your emulator's or board's documentation for more information. The following environment variables may be useful in such situations:

`PATH`
: `PATH` is an environment variable used on Unix-like or Microsoft Windows operating systems to specify a set of directories where executable programs are located.

2.4 Application Development

Note

In this document, we'll assume:

- your **application directory**, <app>, is something like `<home>/zephyrproject/app`
- its **build directory** is `<app>/build`

These terms are defined below. On Linux/macOS, <home> is equivalent to ~. On Windows, it's `%userprofile%`.

Keeping your application inside the workspace (`<home>/zephyrproject`) makes it easier to use `west build` and other commands with it. (You can put your application anywhere as long as *ZEPHYR_BASE* is set appropriately, though.)

2.4.1 Overview

Zephyr's build system is based on CMake.

The build system is application-centric, and requires Zephyr-based applications to initiate building the Zephyr source code. The application build controls the configuration and build process of both the application and Zephyr itself, compiling them into a single binary.

The main zephyr repository contains Zephyr's source code, configuration files, and build system. You also likely have installed various *Modules (External projects)* alongside the zephyr repository, which provide third party source code integration.

The files in the **application directory** link Zephyr and any modules with the application. This directory contains all application-specific files, such as application-specific configuration files and source code.

Here are the files in a simple Zephyr application:

```
<app>
├── CMakeLists.txt
├── app.overlay
├── prj.conf
├── VERSION
└── src
    └── main.c
```

These contents are:

- **CMakeLists.txt**: This file tells the build system where to find the other application files, and links the application directory with Zephyr's CMake build system. This link provides features supported by Zephyr's build system, such as board-specific configuration files, the ability to run and debug compiled binaries on real or emulated hardware, and more.
- **app.overlay**: This is a devicetree overlay file that specifies application-specific changes which should be applied to the base devicetree for any board you build for. The purpose of devicetree overlays is usually to configure something about the hardware used by the application.

  The build system looks for `app.overlay` by default, but you can add more devicetree overlays, and other default files are also searched for.

  See *Devicetree* for more information about devicetree.
- **prj.conf**: This is a Kconfig fragment that specifies application-specific values for one or more Kconfig options. These application settings are merged with other settings to produce the final configuration. The purpose of Kconfig fragments is usually to configure the software features used by the application.

  The build system looks for `prj.conf` by default, but you can add more Kconfig fragments, and other default files are also searched for.

  See *Kconfig Configuration* below for more information.
- **VERSION**: A text file that contains several version information fields. These fields let you manage the lifecycle of the application and automate providing the application version when signing application images.

  See *Application version management* for more information about this file and how to use it.
- **main.c**: A source code file. Applications typically contain source files written in C, C++, or assembly language. The Zephyr convention is to place them in a subdirectory of `<app>` named `src`.

Once an application has been defined, you will use CMake to generate a **build directory**, which contains the files you need to build the application and Zephyr, then link them together into a final binary you can run on your board. The easiest way to do this is with *west build*, but you can use CMake directly also. Application build artifacts are always generated in a separate build directory: Zephyr does not support "in-tree" builds.

The following sections describe how to create, build, and run Zephyr applications, followed by more detailed reference material.

2.4.2 Application types

We distinguish three basic types of Zephyr application based on where <app> is located:

Application type	<app> location
repository	zephyr repository
workspace	west workspace where Zephyr is installed
freestanding	other locations

We'll discuss these more below. To learn how the build system supports each type, see *Zephyr CMake Package*.

Zephyr repository application

An application located within the `zephyr` source code repository in a Zephyr *west workspace* is referred to as a Zephyr repository application. In the following example, the hello_world sample is a Zephyr repository application:

```
zephyrproject/
├── .west/
│   └── config
└── zephyr/
    ├── arch/
    ├── boards/
    ├── cmake/
    ├── samples/
    │   ├── hello_world/
    │   └── ...
    ├── tests/
    └── ...
```

Zephyr workspace application

An application located within a *workspace*, but outside the zephyr repository itself, is referred to as a Zephyr workspace application. In the following example, `app` is a Zephyr workspace application:

```
zephyrproject/
├── .west/
│   └── config
├── zephyr/
├── bootloader/
├── modules/
├── tools/
├── <vendor/private-repositories>/
└── applications/
    └── app/
```

Zephyr freestanding application

A Zephyr application located outside of a Zephyr *workspace* is referred to as a Zephyr freestanding application. In the following example, `app` is a Zephyr freestanding application:

```
<home>/
├── zephyrproject/
│     ├── .west/
│     │    └── config
│     ├── zephyr/
│     ├── bootloader/
│     ├── modules/
│     └── ...
│
└── app/
     ├── CMakeLists.txt
     ├── prj.conf
     └── src/
         └── main.c
```

2.4.3 Creating an Application

In Zephyr, you can either use a reference workspace application or create your application by hand.

Using a Reference Workspace Application

The example-application Git repository contains a reference *workspace application*. It is recommended to use it as a reference when creating your own application as described in the following sections.

The example-application repository demonstrates how to use several commonly-used features, such as:

- Custom *board ports*
- Custom *devicetree bindings*
- Custom *device drivers*
- Continuous Integration (CI) setup, including using *twister*
- A custom west *extension command*

Basic example-application Usage The easiest way to get started with the example-application repository within an existing Zephyr workspace is to follow these steps:

```
cd <home>/zephyrproject
git clone https://github.com/zephyrproject-rtos/example-application my-app
```

The directory name `my-app` above is arbitrary: change it as needed. You can now go into this directory and adapt its contents to suit your needs. Since you are using an existing Zephyr workspace, you can use `west build` or any other west commands to build, flash, and debug.

Advanced example-application Usage You can also use the example-application repository as a starting point for building your own customized Zephyr-based software distribution. This lets you do things like:

- remove Zephyr modules you don't need
- add additional custom repositories of your own
- override repositories provided by Zephyr with your own versions

- share the results with others and collaborate further

The example-application repository contains a `west.yml` file and is therefore also a west *manifest repository*. Use this to create a new, customized workspace by following these steps:

```
cd <home>
mkdir my-workspace
cd my-workspace
git clone https://github.com/zephyrproject-rtos/example-application my-manifest-repo
west init -l my-manifest-repo
```

This will create a new workspace with the *T2 topology*, with `my-manifest-repo` as the manifest repository. The `my-workspace` and `my-manifest-repo` names are arbitrary: change them as needed.

Next, customize the manifest repository. The initial contents of this repository will match the example-application's contents when you clone it. You can then edit `my-manifest-repo/west.yml` to your liking, changing the set of repositories in it as you wish. See *Manifest Imports* for many examples of how to add or remove different repositories from your workspace as needed. Make any other changes you need to other files.

When you are satisfied, you can run:

```
west update
```

and your workspace will be ready for use.

If you push the resulting `my-manifest-repo` repository somewhere else, you can share your work with others. For example, let's say you push the repository to `https://git.example.com/my-manifest-repo`. Other people can then set up a matching workspace by running:

```
west init -m https://git.example.com/my-manifest-repo my-workspace
cd my-workspace
west update
```

From now on, you can collaborate on the shared software by pushing changes to the repositories you are using and updating `my-manifest-repo/west.yml` as needed to add and remove repositories, or change their contents.

Creating an Application by Hand

You can follow these steps to create a basic application directory from scratch. However, using the example-application repository or one of Zephyr's samples-and-demos as a starting point is likely to be easier.

1. Create an application directory.

   For example, in a Unix shell or Windows `cmd.exe` prompt:

   ```
   mkdir app
   ```

   Warning

   Building Zephyr or creating an application in a directory with spaces anywhere on the path is not supported. So the Windows path `C:\Users\YourName\app` will work, but `C:\Users\Your Name\app` will not.

2. Create your source code files.

   It's recommended to place all application source code in a subdirectory named `src`. This makes it easier to distinguish between project files and sources.

Continuing the previous example, enter:

```
cd app
mkdir src
```

3. Place your application source code in the `src` sub-directory. For this example, we'll assume you created a file named `src/main.c`.
4. Create a file named `CMakeLists.txt` in the app directory with the following contents:

```
cmake_minimum_required(VERSION 3.20.0)

find_package(Zephyr)
project(my_zephyr_app)

target_sources(app PRIVATE src/main.c)
```

Notes:

- The `cmake_minimum_required()` call is required by CMake. It is also invoked by the Zephyr package on the next line. CMake will error out if its version is older than either the version in your `CMakeLists.txt` or the version number in the Zephyr package.
- `find_package(Zephyr)` pulls in the Zephyr build system, which creates a CMake target named `app` (see *Zephyr CMake Package*). Adding sources to this target is how you include them in the build. The Zephyr package will define `Zephyr-Kernel` as a CMake project and enable support for the `C`, `CXX`, `ASM` languages.
- `project(my_zephyr_app)` defines your application's CMake project. This must be called after `find_package(Zephyr)` to avoid interference with Zephyr's `project(Zephyr-Kernel)`.
- `target_sources(app PRIVATE src/main.c)` is to add your source file to the `app` target. This must come after `find_package(Zephyr)` which defines the target. You can add as many files as you want with `target_sources()`.

5. Create at least one Kconfig fragment for your application (usually named `prj.conf`) and set Kconfig option values needed by your application there. See *Kconfig Configuration*. If no Kconfig options need to be set, create an empty file.
6. Configure any devicetree overlays needed by your application, usually in a file named `app.overlay`. See *Set devicetree overlays*.
7. Set up any other files you may need, such as *twister* configuration files, continuous integration files, documentation, etc.

2.4.4 Important Build System Variables

You can control the Zephyr build system using many variables. This section describes the most important ones that every Zephyr developer should know about.

Note

The variables **BOARD**, **CONF_FILE**, and **DTC_OVERLAY_FILE** can be supplied to the build system in 3 ways (in order of precedence):

- As a parameter to the `west build` or `cmake` invocation via the `-D` command-line switch. If you have multiple overlay files, you should use quotations, `"file1.overlay;file2.overlay"`
- As *Environment Variables*.
- As a `set(<VARIABLE> <VALUE>)` statement in your `CMakeLists.txt`

- `ZEPHYR_BASE`: Zephyr base variable used by the build system. `find_package(Zephyr)` will automatically set this as a cached CMake variable. But `ZEPHYR_BASE` can also be set as an environment variable in order to force CMake to use a specific Zephyr installation.
- `BOARD`: Selects the board that the application's build will use for the default configuration. See boards for built-in boards, and *Board Porting Guide* for information on adding board support.
- `CONF_FILE`: Indicates the name of one or more Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. Each file includes Kconfig configuration values that override the default configuration values.

  See *The Initial Configuration* for more information.
- `EXTRA_CONF_FILE`: Additional Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. This can be useful in order to leave `CONF_FILE` at its default value, but "mix in" some additional configuration options.
- `DTC_OVERLAY_FILE`: One or more devicetree overlay files to use. Multiple files can be separated with semicolons. See *Set devicetree overlays* for examples and *Introduction to devicetree* for information about devicetree and Zephyr.
- `EXTRA_DTC_OVERLAY_FILE`: Additional devicetree overlay files to use. Multiple files can be separated with semicolons. This can be useful to leave `DTC_OVERLAY_FILE` at its default value, but "mix in" some additional overlay files.
- `SHIELD`: see *Shields*
- `ZEPHYR_MODULES`: A CMake list containing absolute paths of additional directories with source code, Kconfig, etc. that should be used in the application build. See *Modules (External projects)* for details. If you set this variable, it must be a complete list of all modules to use, as the build system will not automatically pick up any modules from west.
- `EXTRA_ZEPHYR_MODULES`: Like `ZEPHYR_MODULES`, except these will be added to the list of modules found via west, instead of replacing it.
- `FILE_SUFFIX`: Optional suffix for filenames that will be added to Kconfig fragments and devicetree overlays (if these files exists, otherwise will fallback to the name without the prefix). See *File Suffixes* for details.

Note

You can use a *Zephyr Build Configuration CMake packages* to share common settings for these variables.

2.4.5 Application CMakeLists.txt

Every application must have a `CMakeLists.txt` file. This file is the entry point, or top level, of the build system. The final `zephyr.elf` image contains both the application and the kernel libraries.

This section describes some of what you can do in your `CMakeLists.txt`. Make sure to follow these steps in order.

1. If you only want to build for one board, add the name of the board configuration for your application on a new line. For example:

   ```
   set(BOARD qemu_x86)
   ```

   Refer to boards for more information on available boards.

The Zephyr build system determines a value for **BOARD** by checking the following, in order (when a BOARD value is found, CMake stops looking further down the list):

- Any previously used value as determined by the CMake cache takes highest precedence. This ensures you don't try to run a build with a different **BOARD** value than you set during the build configuration step.
- Any value given on the CMake command line (directly or indirectly via `west build`) using `-DBOARD=YOUR_BOARD` will be checked for and used next.
- If an *environment variable* `BOARD` is set, its value will then be used.
- Finally, if you set `BOARD` in your application `CMakeLists.txt` as described in this step, this value will be used.

2. If your application uses a configuration file or files other than the usual `prj.conf`, add lines setting the **CONF_FILE** variable to these files appropriately. If multiple filenames are given, separate them by a single space or semicolon. CMake lists can be used to build up configuration fragment files in a modular way when you want to avoid setting **CONF_FILE** in a single place. For example:

```
set(CONF_FILE "fragment_file1.conf")
list(APPEND CONF_FILE "fragment_file2.conf")
```

   See *The Initial Configuration* for more information.

3. If your application uses devicetree overlays, you may need to set *DTC_OVERLAY_FILE*. See *Set devicetree overlays*.

4. If your application has its own kernel configuration options, create a `Kconfig` file in the same directory as your application's `CMakeLists.txt`.

   See *the Kconfig section of the manual* for detailed Kconfig documentation.

   An (unlikely) advanced use case would be if your application has its own unique configuration **options** that are set differently depending on the build configuration.

   If you just want to set application specific **values** for existing Zephyr configuration options, refer to the **CONF_FILE** description above.

   Structure your `Kconfig` file like this:

```
# SPDX-License-Identifier: Apache-2.0

mainmenu "Your Application Name"

# Your application configuration options go here

# Sources Kconfig.zephyr in the Zephyr root directory.
#
# Note: All 'source' statements work relative to the Zephyr root directory (due
# to the $srctree environment variable being set to $ZEPHYR_BASE). If you want
# to 'source' relative to the current Kconfig file instead, use 'rsource' (or a
# path relative to the Zephyr root).
source "Kconfig.zephyr"
```

   Note

   Environment variables in `source` statements are expanded directly, so you do not need to define an `option env="ZEPHYR_BASE"` Kconfig "bounce" symbol. If you use such a symbol, it must have the same name as the environment variable.

   See *Kconfig extensions* for more information.

The `Kconfig` file is automatically detected when placed in the application directory, but it is also possible for it to be found elsewhere if the CMake variable `KCONFIG_ROOT` is set with an absolute path.

5. Specify that the application requires Zephyr on a new line, **after any lines added from the steps above**:

```
find_package(Zephyr)
project(my_zephyr_app)
```

> **Note**
>
> `find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})` can be used if enforcing a specific Zephyr installation by explicitly setting the `ZEPHYR_BASE` environment variable should be supported. All samples in Zephyr supports the `ZEPHYR_BASE` environment variable.

6. Now add any application source files to the 'app' target library, each on their own line, like so:

```
target_sources(app PRIVATE src/main.c)
```

Below is a simple example `CMakeList.txt`:

```
set(BOARD qemu_x86)

find_package(Zephyr)
project(my_zephyr_app)

target_sources(app PRIVATE src/main.c)
```

The Cmake property `HEX_FILES_TO_MERGE` leverages the application configuration provided by Kconfig and CMake to let you merge externally built hex files with the hex file generated when building the Zephyr application. For example:

```
set_property(GLOBAL APPEND PROPERTY HEX_FILES_TO_MERGE
    ${app_bootloader_hex}
    ${PROJECT_BINARY_DIR}/${KERNEL_HEX_NAME}
    ${app_provision_hex})
```

2.4.6 CMakeCache.txt

CMake uses a CMakeCache.txt file as persistent key/value string storage used to cache values between runs, including compile and build options and paths to library dependencies. This cache file is created when CMake is run in an empty build folder.

For more details about the CMakeCache.txt file see the official CMake documentation runningcmake .

2.4.7 Application Configuration

Application Configuration Directory

Zephyr will use configuration files from the application's configuration directory except for files with an absolute path provided by the arguments described earlier, for example `CONF_FILE`, `EXTRA_CONF_FILE`, `DTC_OVERLAY_FILE`, and `EXTRA_DTC_OVERLAY_FILE`.

The application configuration directory is defined by the APPLICATION_CONFIG_DIR variable.

APPLICATION_CONFIG_DIR will be set by one of the sources below with the highest priority listed first.

1. If APPLICATION_CONFIG_DIR is specified by the user with -DAPPLICATION_CONFIG_DIR=<path> or in a CMake file before find_package(Zephyr) then this folder is used a the application's configuration directory.
2. The application's source directory.

Kconfig Configuration

Application configuration options are usually set in prj.conf in the application directory. For example, C++ support could be enabled with this assignment:

```
CONFIG_CPP=y
```

Looking at existing samples is a good way to get started.

See *Setting Kconfig configuration values* for detailed documentation on setting Kconfig configuration values. The *The Initial Configuration* section on the same page explains how the initial configuration is derived. See kconfig-search for a complete list of configuration options. See *Hardening Tool* for security information related with Kconfig options.

The other pages in the *Kconfig section of the manual* are also worth going through, especially if you planning to add new configuration options.

Experimental features Zephyr is a project under constant development and thus there are features that are still in early stages of their development cycle. Such features will be marked [EXPERIMENTAL] in their Kconfig title.

The CONFIG_WARN_EXPERIMENTAL setting can be used to enable warnings at CMake configure time if any experimental feature is enabled.

```
CONFIG_WARN_EXPERIMENTAL=y
```

For example, if option CONFIG_FOO is experimental, then enabling it and CONFIG_WARN_EXPERIMENTAL will print the following warning at CMake configure time when you build an application:

```
warning: Experimental symbol FOO is enabled.
```

Devicetree Overlays

See *Set devicetree overlays*.

File Suffixes

Zephyr applications might want to have a single code base with multiple configurations for different build/product variants which would necessitate different Kconfig options and devicetree configuration. In order to better configure this, Zephyr provides a FILE_SUFFIX option when configuring applications that can be automatically appended to filenames. This is applied to Kconfig fragments and board overlays but with a fallback so that if such files do not exist, the files without these suffixes will be used instead.

Given the following example project layout:

```
<app>
├── CMakeLists.txt
├── prj.conf
├── prj_mouse.conf
├── boards
│   ├── native_sim.overlay
│   └── qemu_cortex_m3_mouse.overlay
└── src
    └── main.c
```

- If this is built normally without `FILE_SUFFIX` being defined for `native_sim` then `prj.conf` and `boards/native_sim.overlay` will be used.
- If this is build normally without `FILE_SUFFIX` being defined for `qemu_cortex_m3` then `prj.conf` will be used, no application devicetree overlay will be used.
- If this is built with `FILE_SUFFIX` set to `mouse` for `native_sim` then `prj_mouse.conf` and `boards/native_sim.overlay` will be used (there is no `native_sim_mouse.overlay` file so it falls back to `native_sim.overlay`).
- If this is build with `FILE_SUFFIX` set to `mouse` for `qemu_cortex_m3` then `prj_mouse.conf` will be used and `boards/qemu_cortex_m3_mouse.overlay` will be used.

Note

When `CONF_FILE` is set in the form of `prj_X.conf` then the `X` will be used as the build type. If this is combined with `FILE_SUFFIX` then the file suffix option will take priority over the build type.

2.4.8 Application-Specific Code

Application-specific source code files are normally added to the application's `src` directory. If the application adds a large number of files the developer can group them into sub-directories under `src`, to whatever depth is needed.

Application-specific source code should not use symbol name prefixes that have been reserved by the kernel for its own use. For more information, see Naming Conventions.

Third-party Library Code

It is possible to build library code outside the application's `src` directory but it is important that both application and library code targets the same Application Binary Interface (ABI). On most architectures there are compiler flags that control the ABI targeted, making it important that both libraries and applications have certain compiler flags in common. It may also be useful for glue code to have access to Zephyr kernel header files.

To make it easier to integrate third-party components, the Zephyr build system has defined CMake functions that give application build scripts access to the zephyr compiler options. The functions are documented and defined in cmake/modules/extensions.cmake and follow the naming convention `zephyr_get_<type>_<format>`.

The following variables will often need to be exported to the third-party build system.

- `CMAKE_C_COMPILER`, `CMAKE_AR`.
- `ARCH` and `BOARD`, together with several variables that identify the Zephyr kernel version.

samples/application_development/external_lib is a sample project that demonstrates some of these features.

2.4.9 Building an Application

The Zephyr build system compiles and links all components of an application into a single application image that can be run on simulated hardware or real hardware.

Like any other CMake-based system, the build process takes place *in two stages*. First, build files (also known as a buildsystem) are generated using the `cmake` command-line tool while specifying a generator. This generator determines the native build tool the buildsystem will use in the second stage. The second stage runs the native build tool to actually build the source files and generate an image. To learn more about these concepts refer to the CMake introduction in the official CMake documentation.

Although the default build tool in Zephyr is *west*, Zephyr's meta-tool, which invokes `cmake` and the underlying build tool (`ninja` or `make`) behind the scenes, you can also choose to invoke `cmake` directly if you prefer. On Linux and macOS you can choose between the `make` and `ninja` generators (i.e. build tools), whereas on Windows you need to use `ninja`, since `make` is not supported on this platform. For simplicity we will use `ninja` throughout this guide, and if you choose to use `west build` to build your application know that it will default to `ninja` under the hood.

As an example, let's build the Hello World sample for the `reel_board`:

Using west:

```
west build -b reel_board samples/hello_world
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild
```

On Linux and macOS, you can also build with `make` instead of `ninja`:

Using west:

- to use `make` just once, add `-- -G"Unix Makefiles"` to the west build command line; see the *west build* documentation for an example.
- to use `make` by default from now on, run `west config build.generator "Unix Makefiles"`.

Using CMake directly:

```
# Use cmake to configure a Make-based buildsystem:
cmake -Bbuild -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
make -Cbuild
```

Basics

1. Navigate to the application directory <app>.
2. Enter the following commands to build the application's `zephyr.elf` image for the board specified in the command-line parameters:

   Using west:

   ```
   west build -b <board>
   ```

   Using CMake and ninja:

```
mkdir build && cd build

# Use cmake to configure a Ninja-based buildsystem:
cmake -GNinja -DBOARD=<board> ..

# Now run the build tool on the generated build system:
ninja
```

If desired, you can build the application using the configuration settings specified in an alternate `.conf` file using the `CONF_FILE` parameter. These settings will override the settings in the application's `.config` file or its default `.conf` file. For example:

Using west:

```
west build -b <board> -- -DCONF_FILE=prj.alternate.conf
```

Using CMake and ninja:

```
mkdir build && cd build
cmake -GNinja -DBOARD=<board> -DCONF_FILE=prj.alternate.conf ..
ninja
```

As described in the previous section, you can instead choose to permanently set the board and configuration settings by either exporting **`BOARD`** and **`CONF_FILE`** environment variables or by setting their values in your `CMakeLists.txt` using `set()` statements. Additionally, `west` allows you to *set a default board*.

Build Directory Contents

When using the Ninja generator a build directory looks like this:

```
<app>/build
├── build.ninja
├── CMakeCache.txt
├── CMakeFiles
├── cmake_install.cmake
├── rules.ninja
└── zephyr
```

The most notable files in the build directory are:

- `build.ninja`, which can be invoked to build the application.
- A `zephyr` directory, which is the working directory of the generated build system, and where most generated files are created and stored.

After running `ninja`, the following build output files will be written to the `zephyr` sub-directory of the build directory. (This is **not the Zephyr base directory**, which contains the Zephyr source code etc. and is described above.)

- `.config`, which contains the configuration settings used to build the application.

> **Note**
>
> The previous version of `.config` is saved to `.config.old` whenever the configuration is updated. This is for convenience, as comparing the old and new versions can be handy.

- Various object files (`.o` files and `.a` files) containing compiled kernel and application code.
- `zephyr.elf`, which contains the final combined application and kernel binary. Other binary output formats, such as `.hex` and `.bin`, are also supported.

Rebuilding an Application

Application development is usually fastest when changes are continually tested. Frequently rebuilding your application makes debugging less painful as the application becomes more complex. It's usually a good idea to rebuild and test after any major changes to the application's source files, CMakeLists.txt files, or configuration settings.

Important

The Zephyr build system rebuilds only the parts of the application image potentially affected by the changes. Consequently, rebuilding an application is often significantly faster than building it the first time.

Sometimes the build system doesn't rebuild the application correctly because it fails to recompile one or more necessary files. You can force the build system to rebuild the entire application from scratch with the following procedure:

1. Open a terminal console on your host computer, and navigate to the build directory `<app>/build`.
2. Enter one of the following commands, depending on whether you want to use `west` or `cmake` directly to delete the application's generated files, except for the `.config` file that contains the application's current configuration information.

   ```
   west build -t clean
   ```

   or

   ```
   ninja clean
   ```

   Alternatively, enter one of the following commands to delete *all* generated files, including the `.config` files that contain the application's current configuration information for those board types.

   ```
   west build -t pristine
   ```

   or

   ```
   ninja pristine
   ```

   If you use west, you can take advantage of its capability to automatically *make the build folder pristine* whenever it is required.
3. Rebuild the application normally following the steps specified in *Building an Application* above.

Building for a board revision

The Zephyr build system has support for specifying multiple hardware revisions of a single board with small variations. Using revisions allows the board support files to make minor adjustments to a board configuration without duplicating all the files described in *Create your board directory* for each revision.

To build for a particular revision, use `<board>@<revision>` instead of plain `<board>`. For example:

Using west:

```
west build -b <board>@<revision>
```

Using CMake and ninja:

```
mkdir build && cd build
cmake -GNinja -DBOARD=<board>@<revision> ..
ninja
```

Check your board's documentation for details on whether it has multiple revisions, and what revisions are supported.

When targeting a board revision, the active revision will be printed at CMake configure time, like this:

```
-- Board: plank, Revision: 1.5.0
```

2.4.10 Run an Application

An application image can be run on a real board or emulated hardware.

Running on a Board

Most boards supported by Zephyr let you flash a compiled binary using the `flash` target to copy the binary to the board and run it. Follow these instructions to flash and run an application on real hardware:

1. Build your application, as described in *Building an Application*.
2. Make sure your board is attached to your host computer. Usually, you'll do this via USB.
3. Run one of these console commands from the build directory, `<app>/build`, to flash the compiled Zephyr image and run it on your board:

   ```
   west flash
   ```

   or

   ```
   ninja flash
   ```

The Zephyr build system integrates with the board support files to use hardware-specific tools to flash the Zephyr binary to your hardware, then run it.

Each time you run the flash command, your application is rebuilt and flashed again.

In cases where board support is incomplete, flashing via the Zephyr build system may not be supported. If you receive an error message about flash support being unavailable, consult your board's documentation for additional information on how to flash your board.

> **Note**
>
> When developing on Linux, it's common to need to install board-specific udev rules to enable USB device access to your board as a non-root user. If flashing fails, consult your board's documentation to see if this is necessary.

Running in an Emulator

Zephyr has built-in emulator support for QEMU. It allows you to run and test an application virtually, before (or in lieu of) loading and running it on actual target hardware.

Check out *Beyond the Getting Started Guide* for additional steps needed on Windows.

Follow these instructions to run an application via QEMU:

1. Build your application for one of the QEMU boards, as described in *Building an Application*.

   For example, you could set `BOARD` to:

   - `qemu_x86` to emulate running on an x86-based board
   - `qemu_cortex_m3` to emulate running on an ARM Cortex M3-based board

2. Run one of these console commands from the build directory, `<app>/build`, to run the Zephyr binary in QEMU:

   ```
   west build -t run
   ```

   or

   ```
   ninja run
   ```

3. Press `Ctrl A, X` to stop the application from running in QEMU.

   The application stops running and the terminal console prompt redisplays.

Each time you execute the run command, your application is rebuilt and run again.

Note

If the (Linux only) *Zephyr SDK* is installed, the `run` target will use the SDK's QEMU binary by default. To use another version of QEMU, *set the environment variable* `QEMU_BIN_PATH` to the path of the QEMU binary you want to use instead.

Note

You can choose a specific emulator by appending `_<emulator>` to your target name, for example `west build -t run_qemu` or `ninja run_qemu` for QEMU.

2.4.11 Custom Board, Devicetree and SOC Definitions

In cases where the board or platform you are developing for is not yet supported by Zephyr, you can add board, Devicetree and SOC definitions to your application without having to add them to the Zephyr tree.

The structure needed to support out-of-tree board and SOC development is similar to how boards and SOCs are maintained in the Zephyr tree. By using this structure, it will be much easier to upstream your platform related work into the Zephyr tree after your initial development is done.

Add the custom board to your application or a dedicated repository using the following structure:

```
boards/
soc/
CMakeLists.txt
prj.conf
README.rst
src/
```

where the `boards` directory hosts the board you are building for:

```
.
├── boards
│   └── vendor
│       └── my_custom_board
```

(continues on next page)

(continued from previous page)

```
|           ├── doc
|           |   └── img
|           └── support
└── src
```

and the soc directory hosts any SOC code. You can also have boards that are supported by a SOC that is available in the Zephyr tree.

Boards

Use the vendor name as the folder name (which must match the vendor prefix in dts/bindings/vendor-prefixes.txt if submitting upstream to Zephyr, or be `others` if it is not a vendor board) under `boards` for `my_custom_board`.

Documentation (under `doc/`) and support files (under `support/`) are optional, but will be needed when submitting to Zephyr.

The contents of `my_custom_board` should follow the same guidelines for any Zephyr board, and provide the following files:

```
my_custom_board_defconfig
my_custom_board.dts
my_custom_board.yaml
board.cmake
board.h
CMakeLists.txt
doc/
Kconfig.my_custom_board
Kconfig.defconfig
support/
```

Once the board structure is in place, you can build your application targeting this board by specifying the location of your custom board information with the `-DBOARD_ROOT` parameter to the CMake build system:

Using west:

```
west build -b <board name> -- -DBOARD_ROOT=<path to boards>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DBOARD_ROOT=<path to boards> .
ninja -Cbuild
```

This will use your custom board configuration and will generate the Zephyr binary into your application directory.

You can also define the `BOARD_ROOT` variable in the application `CMakeLists.txt` file. Make sure to do so **before** pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`.

Note

When specifying `BOARD_ROOT` in a CMakeLists.txt, then an absolute path must be provided, for example `list(APPEND BOARD_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-board-root>)`. When using `-DBOARD_ROOT=<board-root>` both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

SOC Definitions

Similar to board support, the structure is similar to how SOCs are maintained in the Zephyr tree, for example:

```
soc
└── st
    └── stm32
        ├── common
        └── stm32l0x
```

The file soc/Kconfig will create the top-level `SoC/CPU/Configuration Selection` menu in Kconfig.

Out of tree SoC definitions can be added to this menu using the `SOC_ROOT` CMake variable. This variable contains a semicolon-separated list of directories which contain SoC support files.

Following the structure above, the following files can be added to load more SoCs into the menu.

```
soc
└── st
    └── stm32
        └── stm32l0x
            ├── Kconfig
            ├── Kconfig.soc
            └── Kconfig.defconfig
```

The Kconfig files above may describe the SoC or load additional SoC Kconfig files.

An example of loading `stm31l0` specific Kconfig files in this structure:

```
soc
└── st
    └── stm32
        ├── Kconfig.soc
        └── stm32l0x
            └── Kconfig.soc
```

can be done with the following content in `st/stm32/Kconfig.soc`:

```
rsource "*/Kconfig.soc"
```

Once the SOC structure is in place, you can build your application targeting this platform by specifying the location of your custom platform information with the `-DSOC_ROOT` parameter to the CMake build system:

Using west:

```
west build -b <board name> -- -DSOC_ROOT=<path to soc> -DBOARD_ROOT=<path to boards>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DSOC_ROOT=<path to soc> -DBOARD_ROOT=<path to␣
↪boards> .
ninja -Cbuild
```

This will use your custom platform configurations and will generate the Zephyr binary into your application directory.

See *Build settings* for information on setting SOC_ROOT in a module's `zephyr/module.yml` file.

Or you can define the `SOC_ROOT` variable in the application `CMakeLists.txt` file. Make sure to do so **before** pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`.

Note

When specifying SOC_ROOT in a CMakeLists.txt, then an absolute path must be provided, for example `list(APPEND SOC_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-soc-root>`. When using -DSOC_ROOT=<soc-root> both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Devicetree Definitions

Devicetree directory trees are found in APPLICATION_SOURCE_DIR, BOARD_DIR, and ZEPHYR_BASE, but additional trees, or DTS_ROOTs, can be added by creating this directory tree:

```
include/
dts/common/
dts/arm/
dts/
dts/bindings/
```

Where 'arm' is changed to the appropriate architecture. Each directory is optional. The binding directory contains bindings and the other directories contain files that can be included from DT sources.

Once the directory structure is in place, you can use it by specifying its location through the DTS_ROOT CMake Cache variable:

Using west:

```
west build -b <board name> -- -DDTS_ROOT=<path to dts root>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DDTS_ROOT=<path to dts root> .
ninja -Cbuild
```

You can also define the variable in the application CMakeLists.txt file. Make sure to do so **before** pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`.

Note

When specifying DTS_ROOT in a CMakeLists.txt, then an absolute path must be provided, for example `list(APPEND DTS_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-dts-root>`. When using -DDTS_ROOT=<dts-root> both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Devicetree source are passed through the C preprocessor, so you can include files that can be located in a DTS_ROOT directory. By convention devicetree include files have a .dtsi extension.

You can also use the preprocessor to control the content of a devicetree file, by specifying directives through the DTS_EXTRA_CPPFLAGS CMake Cache variable:

Using west:

```
west build -b <board name> -- -DDTS_EXTRA_CPPFLAGS=-DTEST_ENABLE_FEATURE
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DDTS_EXTRA_CPPFLAGS=-DTEST_ENABLE_FEATURE .
ninja -Cbuild
```

2.5 Debugging

2.5.1 Application Debugging

This section is a quick hands-on reference to start debugging your application with QEMU. Most content in this section is already covered in QEMU and GNU_Debugger reference manuals.

In this quick reference, you'll find shortcuts, specific environmental variables, and parameters that can help you to quickly set up your debugging environment.

The simplest way to debug an application running in QEMU is using the GNU Debugger and setting a local GDB server in your development system through QEMU.

You will need an ELF (Executable and Linkable Format) binary image for debugging purposes. The build system generates the image in the build directory. By default, the kernel binary name is `zephyr.elf`. The name can be changed using `CONFIG_KERNEL_BIN_NAME`.

GDB server

We will use the standard 1234 TCP port to open a GDB (GNU Debugger) server instance. This port number can be changed for a port that best suits the development environment. There are multiple ways to do this. Each way starts a QEMU instance with the processor halted at startup and with a GDB server instance listening for a connection.

Running QEMU directly You can run QEMU to listen for a "gdb connection" before it starts executing any code to debug it.

```
qemu -s -S <image>
```

will setup Qemu to listen on port 1234 and wait for a GDB connection to it.

The options used above have the following meaning:

- `-S` Do not start CPU at startup; rather, you must type 'c' in the monitor.
- `-s` Shorthand for `-gdb tcp::1234`: open a GDB server on TCP port 1234.

Running QEMU via `ninja` Run the following inside the build directory of an application:

```
ninja debugserver
```

QEMU will write the console output to the path specified in **`${QEMU_PIPE}`** via CMake, typically `qemu-fifo` within the build directory. You may monitor this file during the run with **`tail -f qemu-fifo`**.

Running QEMU via `west` Run the following from your project root:

```
west build -t debugserver_qemu
```

QEMU will write the console output to the terminal from which you invoked **`west`**.

Configuring the `gdbserver` listening device The Kconfig option `CONFIG_QEMU_GDBSERVER_LISTEN_DEV` controls the listening device, which can be a TCP port number or a path to a character device. GDB releases 9.0 and newer also support Unix domain sockets.

If the option is unset, then the QEMU invocation will lack a `-s` or a `-gdb` parameter. You can then use the `QEMU_EXTRA_FLAGS` shell environment variable to pass in your own listen device configuration.

GDB client

Connect to the server by running **gdb** and giving these commands:

```
$ path/to/gdb path/to/zephyr.elf
(gdb) target remote localhost:1234
(gdb) dir ZEPHYR_BASE
```

> **Note**
>
> Substitute the correct *ZEPHYR_BASE* for your system.

You can use a local GDB configuration `.gdbinit` to initialize your GDB instance on every run. Your home directory is a typical location for `.gdbinit`, but you can configure GDB to load from other locations, including the directory from which you invoked **gdb**. This example file performs the same configuration as above:

```
target remote localhost:1234
dir ZEPHYR_BASE
```

Alternate interfaces GDB provides a curses-based interface that runs in the terminal. Pass the `--tui` option when invoking **gdb** or give the `tui enable` command within **gdb**.

> **Note**
>
> The GDB version on your development system might not support the `--tui` option. Please make sure you use the GDB binary from the SDK which corresponds to the toolchain that has been used to build the binary.

Finally, the command below connects to the GDB server using the DDD (Data Display Debugger), a graphical frontend for GDB. The following command loads the symbol table from the ELF binary file, in this instance, `zephyr.elf`.

```
ddd --gdb --debugger "gdb zephyr.elf"
```

Both commands execute **gdb**. The command name might change depending on the toolchain you are using and your cross-development tools.

ddd may not be installed in your development system by default. Follow your system instructions to install it. For example, use **sudo apt-get install ddd** on an Ubuntu system.

Debugging

As configured above, when you connect the GDB client, the application will be stopped at system startup. You may set breakpoints, step through code, etc. as when running the application directly within **gdb**.

> **Note**
>
> **gdb** will not print the system console output as the application runs, unlike when you run a native application in GDB directly. If you just **continue** after connecting the client, the application will run, but nothing will appear to happen. Check the console output as described above.

2.5.2 Debug with Eclipse

Overview

CMake supports generating a project description file that can be imported into the Eclipse Integrated Development Environment (IDE) and used for graphical debugging.

The GNU MCU Eclipse plug-ins provide a mechanism to debug ARM projects in Eclipse with pyOCD, Segger J-Link, and OpenOCD debugging tools.

The following tutorial demonstrates how to debug a Zephyr application in Eclipse with pyOCD in Windows. It assumes you have already installed the GCC ARM Embedded toolchain and pyOCD.

Set Up the Eclipse Development Environment

1. Download and install Eclipse IDE for C/C++ Developers.
2. In Eclipse, install the GNU MCU Eclipse plug-ins by opening the menu `Window->Eclipse Marketplace...`, searching for `GNU MCU Eclipse`, and clicking `Install` on the matching result.
3. Configure the path to the pyOCD GDB server by opening the menu `Window->Preferences`, navigating to `MCU`, and setting the `Global pyOCD Path`.

Generate and Import an Eclipse Project

1. Set up a GNU Arm Embedded toolchain as described in *GNU Arm Embedded*.
2. Navigate to a folder outside of the Zephyr tree to build your application.

```
# On Windows
cd %userprofile%
```

> **Note**
>
> If the build directory is a subdirectory of the source directory, as is usually done in Zephyr, CMake will warn:
>
> "The build directory is a subdirectory of the source directory.
>
> This is not supported well by Eclipse. It is strongly recommended to use a build directory which is a sibling of the source directory."

3. Configure your application with CMake and build it with ninja. Note the different CMake generator specified by the `-G"Eclipse CDT4 - Ninja"` argument. This will generate an Eclipse project description file, `.project`, in addition to the usual ninja build files.

   Using west:

```
west build -b frdm_k64f %ZEPHYR_BASE%\samples\synchronization -- -G"Eclipse CDT4 -␣
↪Ninja"
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=frdm_k64f -G"Eclipse CDT4 - Ninja" %ZEPHYR_BASE%\samples\
↪synchronization
ninja -Cbuild
```

4. In Eclipse, import your generated project by opening the menu `File->Import...` and selecting the option `Existing Projects into Workspace`. Browse to your application build directory in the choice, `Select root directory:`. Check the box for your project in the list of projects found and click the `Finish` button.

Create a Debugger Configuration

1. Open the menu `Run->Debug Configurations...`.
2. Select `GDB PyOCD Debugging`, click the `New` button, and configure the following options:
   - In the Main tab:
     - Project: `my_zephyr_app@build`
     - C/C++ Application: `zephyr/zephyr.elf`
   - In the Debugger tab:
     - pyOCD Setup
       - Executable path: `$pyocd_path\$pyocd_executable`
       - Uncheck “Allocate console for semihosting”
     - Board Setup
       - Bus speed: 8000000 Hz
       - Uncheck “Enable semihosting”
     - GDB Client Setup
       - Executable path example (use your `GNUARMEMB_TOOLCHAIN_PATH`): `C:\gcc-arm-none-eabi-6_2017-q2-update\bin\arm-none-eabi-gdb.exe`
   - In the SVD Path tab:
     - File path: `<workspace top>\modules\hal\nxp\mcux\devices\MK64F12\MK64F12.xml`

> **Note**
>
> This is optional. It provides the SoC’s memory-mapped register addresses and bitfields to the debugger.

3. Click the `Debug` button to start debugging.

RTOS Awareness

Support for Zephyr RTOS awareness is implemented in pyOCD v0.11.0 and later. It is compatible with GDB PyOCD Debugging in Eclipse, but you must enable CONFIG_DEBUG_THREAD_INFO=y in your application.

2.5.3 Debugging I2C communication

There is a possibility to log all or some of the I2C transactions done by the application. This feature is enabled by the Kconfig option `CONFIG_I2C_DUMP_MESSAGES`, but it uses the `LOG_DBG` function to print the contents so the `CONFIG_I2C_LOG_LEVEL_DBG` option must also be enabled.

The sample output of the dump looks like this:

```
D: I2C msg: io_i2c_ctrl7_port0, addr=50
D:    W      len=01: 00
D:    R Sr P len=08:
D: contents:
D: 43 42 41 00 00 00 00 00 |CBA.....
```

The first line indicates the I2C controller and the target address of the transaction. In above example, the I2C controller is named `io_i2c_ctrl7_port0` and the target device address is `0x50`

Note

the address, length and contents values are in hexadecimal, but lack the `0x` prefix

Next lines contain messages, both sent and received. The contents of write messages is always shown, while the content of read messages is controlled by a parameter to the function `i2c_dump_msgs_rw`. This function is available for use by user, but is also called internally by `i2c_transfer` API function with read content dump enabled. Before the length parameter, the header of the message is printed using abbreviations:

- W - write message
- R - read message
- Sr - restart bit
- P - stop bit

The above example shows one write message with byte `0x00` representing the address of register to read from the I2C target. After that the log shows the length of received message and following that, the bytes read from the target `43 42 41 00 00 00 00 00`. The content dump consist of both the hex and ASCII representation.

Filtering the I2C communication dump

By default, all I2C communication is logged between all I2C controllers and I2C targets. It may litter the log with unrelated devices and make it difficult to effectively debug the communication with a device of interest.

Enable the Kconfig option `CONFIG_I2C_DUMP_MESSAGES_ALLOWLIST` to create an allowlist of I2C targets to log. The allowlist of devices is configured using the devicetree, for example:

```
/ {
    i2c {
        display0: some-display@a {
            ...
        };
        sensor3: some-sensor@b {
            ...
        };
    };

    i2c-dump-allowlist {
```

(continues on next page)

(continued from previous page)

```
        compatible = "zephyr,i2c-dump-allowlist";
        devices = < &display0 >, < &sensor3 >;
    };
};
```

The filters nodes are identified by the compatible string with `zephyr,i2c-dump-allowlist` value. The devices are selected using the `devices` property with phandles to the devices on the I2C bus.

In the above example, the communication with device `display0` and `sensor3` will be displayed in the log.

2.6 API Status and Guidelines

2.6.1 API Overview

The table lists Zephyr's APIs and information about them, including their current *stability level*. More details about API changes between major releases are available in the zephyr_release_notes.

The version column uses semantic version, and has the following expectations:

- Major version zero (0.y.z) is for initial development. Anything MAY change at any time. The public API SHOULD NOT be considered stable.
  - If minor version is up to one (0.1.z), API is considered *experimental*.
  - If minor version is larger than one (0.y.z | y > 1), API is considered *unstable*.
- Version 1.0.0 defines the public API. The way in which the version number is incremented after this release is dependent on this public API and how it changes.
  - APIs with major versions equal or larger than one (x.y.z | x >= 1) are considered *stable*.
  - All existing stable APIs in Zephyr will be start with version 1.0.0.
- Patch version Z (x.y.Z | x > 0) MUST be incremented if only backwards compatible bug fixes are introduced. A bug fix is defined as an internal change that fixes incorrect behavior.
- Minor version Y (x.Y.z | x > 0) MUST be incremented if new, backwards compatible functionality is introduced to the public API. It MUST be incremented if any public API functionality is marked as deprecated. It MAY be incremented if substantial new functionality or improvements are introduced within the private code. It MAY include patch level changes. Patch version MUST be reset to 0 when minor version is incremented.
- Major version X (x.Y.z | x > 0) MUST be incremented if a compatibility breaking change was made to the API.

Note

Version for existing APIs are initially set based on the current state of the APIs:

- 0.1.0 denotes an *experimental* API
- 0.8.0 denote an *unstable* API,
- and finally 1.0.0 indicates a *stable* APIs.

Changes to APIs in the future will require adapting the version following the guidelines above.

2.6.2 API Lifecycle

Developers using Zephyr's APIs need to know how long they can trust that a given API will not change in future releases. At the same time, developers maintaining and extending Zephyr's APIs need to be able to introduce new APIs that aren't yet fully proven, and to potentially retire old APIs when they're no longer optimal or supported by the underlying platforms.

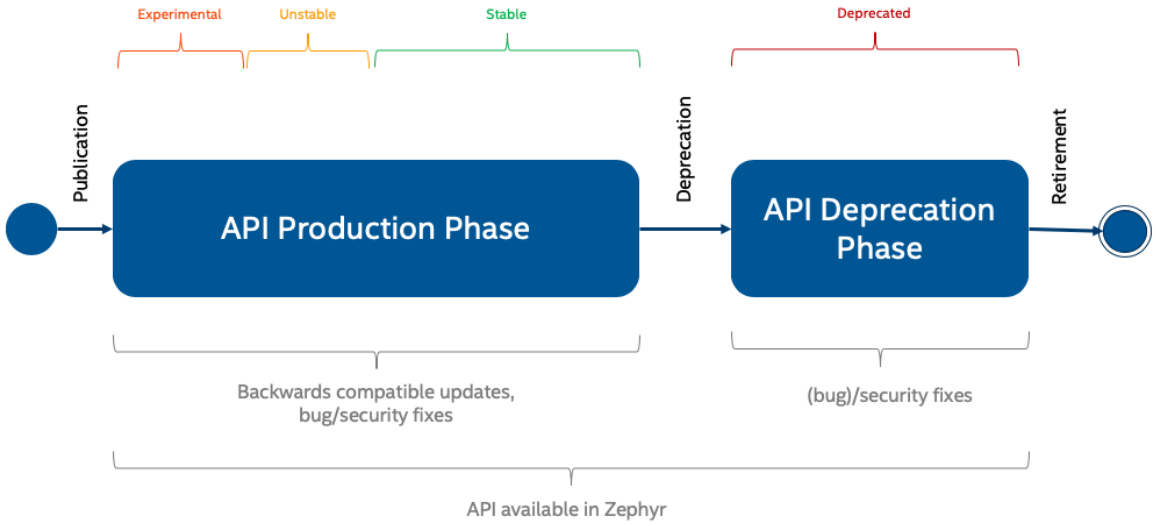

Fig. 2: API Life Cycle

An up-to-date table of all APIs and their maturity level can be found in the *API Overview* page.

Experimental

Experimental APIs denote that a feature was introduced recently, and may change or be removed in future versions. Try it out and provide feedback to the community via the Developer mailing list.

The following requirements apply to all new APIs:

- Documentation of the API (usage) explaining its design and assumptions, how it is to be used, current implementation limitations, and future potential, if appropriate.
- The API introduction should be accompanied by at least one implementation of said API (in the case of peripheral APIs, this corresponds to one driver)
- At least one sample using the new API (may only build on one single board)

When introducing a new and experimental API, mark the API version in the headers where the API is defined. An experimental API shall have a version where the minor version is up to one (0.1.z). (see *API Overview*)

Peripheral APIs (Hardware Related) When introducing an API (public header file with documentation) for a new peripheral or driver subsystem, review of the API is enforced and is driven by the Architecture working group consisting of representatives from different vendors.

The API shall be promoted to `unstable` when it has at least two implementations on different hardware platforms.

Unstable

The API is in the process of settling, but has not yet had sufficient real-world testing to be considered stable. The API is considered generic in nature and can be used on different hardware platforms.

When the API changes status to unstable API, mark the API version in the headers where the API is defined. Unstable APIs shall have a version where the minor version is larger than one (0.y.z | y > 1). (see *API Overview*)

> **Note**
>
> Changes will not be announced.

Peripheral APIs (Hardware Related) The API shall be promoted from `experimental` to `unstable` when it has at least two implementations on different hardware platforms.

Hardware Agnostic APIs For hardware agnostic APIs, multiple applications using it are required to promote an API from `experimental` to `unstable`.

Stable

The API has proven satisfactory, but cleanup in the underlying code may cause minor changes. Backwards-compatibility will be maintained if reasonable.

An API can be declared `stable` after fulfilling the following requirements:

- Test cases for the new API with 100% coverage
- Complete documentation in code. All public interfaces shall be documented and available in online documentation.
- The API has been in-use and was available in at least 2 development releases
- Stable APIs can get backward compatible updates, bug fixes and security fixes at any time.

In order to declare an API `stable`, the following steps need to be followed:

1. A Pull Request must be opened that changes the corresponding entry in the *API Overview* table
2. An email must be sent to the `devel` mailing list announcing the API upgrade request
3. The Pull Request must be submitted for discussion in the next Zephyr Architecture meeting where, barring any objections, the Pull Request will be merged

When the API changes status to stable API, mark the API version in the headers where the API is defined. Stable APIs shall have a version where the major version is one or larger (x.y.z | x >= 1). (see *API Overview*)

Introducing breaking API changes A stable API, as described above, strives to remain backwards-compatible through its life-cycle. There are however cases where fulfilling this objective prevents technical progress, or is simply unfeasible without unreasonable burden on the maintenance of the API and its implementation(s).

A breaking API change is defined as one that forces users to modify their existing code in order to maintain the current behavior of their application. The need for recompilation of applications (without changing the application itself) is not considered a breaking API change.

In order to restrict and control the introduction of a change that breaks the promise of backwards compatibility, the following steps must be followed whenever such a change is considered necessary in order to accept it in the project:

1. An *RFC issue* must be opened on GitHub with the following content:

   ```
   Title:     RFC: Breaking API Change: <subsystem>
   Contents:  - Problem Description:
                - Background information on why the change is required
              - Proposed Change (detailed):
                - Brief description of the API change
              - Detailed RFC:
                - Function call changes
                - Device Tree changes (source and bindings)
                - Kconfig option changes
              - Dependencies:
                - Impact to users of the API, including the steps required
                  to adapt out-of-tree users of the API to the change
   ```

   Instead of a written description of the changes, the RFC issue may link to a Pull Request containing those changes in code form.

2. The RFC issue must be labeled with the GitHub `Breaking API Change` label
3. The RFC issue must be submitted for discussion in the next Zephyr Architecture meeting
4. An email must be sent to the `devel` mailing list with a subject identical to the RFC issue title and that links to the RFC issue

The RFC will then receive feedback through issue comments and will also be discussed in the Zephyr Architecture meeting, where the stakeholders and the community at large will have a chance to discuss it in detail.

Finally, and if not done as part of the first step, a Pull Request must be opened on GitHub. It is left to the person proposing the change to decide whether to introduce both the RFC and the Pull Request at the same time or to wait until the RFC has gathered consensus enough so that the implementation can proceed with confidence that it will be accepted. The Pull Request must include the following:

- A title that matches the RFC issue
- A link to the RFC issue
- The actual changes to the API
  - Changes to the API header file
  - Changes to the API implementation(s)
  - Changes to the relevant API documentation
  - Changes to Device Tree source and bindings

- The changes required to adapt in-tree users of the API to the change. Depending on the scope of this task this might require additional help from the corresponding maintainers
- An entry in the "API Changes" section of the release notes for the next upcoming release
- The labels `API`, `Breaking API Change` and `Release Notes`, as well as any others that are applicable
- The label `Architecture Review` if the RFC was not yet discussed and agreed upon in Zephyr Architecture meeting

Once the steps above have been completed, the outcome of the proposal will depend on the approval of the actual Pull Request by the maintainer of the corresponding subsystem. As with any other Pull Request, the author can request for it to be discussed and ultimately even voted on in the Zephyr TSC meeting.

If the Pull Request is merged then an email must be sent to the `devel` and `user` mailing lists informing them of the change.

The API version shall be changed to signal backward incompatible changes. This is achieved by incrementing the major version (X.y.z | X > 1). It MAY also include minor and patch level changes. Patch and minor versions MUST be reset to 0 when major version is incremented. (see *API Overview*)

Note

Breaking API changes will be listed and described in the migration guide.

Deprecated

Note

Unstable APIs can be removed without deprecation at any time. Deprecation and removal of APIs will be announced in the "API Changes" section of the release notes.

The following are the requirements for deprecating an existing API:

- Deprecation Time (stable APIs): 2 Releases The API needs to be marked as deprecated in at least two full releases. For example, if an API was first deprecated in release 1.14, it will be ready to be removed in 1.16 at the earliest. There may be special circumstances, determined by the Architecture working group, where an API is deprecated sooner.
- What is required when deprecating:
  - Mark as deprecated. This can be done by using the compiler itself (`__deprecated` for function declarations and `__DEPRECATED_MACRO` for macro definitions), or by introducing a Kconfig option (typically one that contains the `DEPRECATED` word in it) that, when enabled, reverts the APIs back to their previous form
  - Document the deprecation
  - Include the deprecation in the "API Changes" of the release notes for the next upcoming release
  - Code using the deprecated API needs to be modified to remove usage of said API
  - The change needs to be atomic and bisectable
  - Create a GitHub issue to track the removal of the deprecated API, and add it to the roadmap targeting the appropriate release (in the example above, 1.16).

During the deprecation waiting period, the API will be in the `deprecated` state. The Zephyr maintainers will track usage of deprecated APIs on `docs.zephyrproject.org` and support developers migrating their code. Zephyr will continue to provide warnings:

- API documentation will inform users that the API is deprecated.
- Attempts to use a deprecated API at build time will log a warning to the console.

Retired

In this phase, the API is removed.

The target removal date is 2 releases after deprecation is announced. The Zephyr maintainers will decide when to actually remove the API: this will depend on how many developers have successfully migrated from the deprecated API, and on how urgently the API needs to be removed.

If it's OK to remove the API, it will be removed. The maintainers will remove the corresponding documentation, and communicate the removal in the usual ways: the release notes, mailing lists, Github issues and pull-requests.

If it's not OK to remove the API, the maintainers will continue to support migration and update the roadmap with the aim to remove the API in the next release.

2.6.3 API Design Guidelines

Zephyr development and evolution is a group effort, and to simplify maintenance and enhancements there are some general policies that should be followed when developing a new capability or interface.

Using Callbacks

Many APIs involve passing a callback as a parameter or as a member of a configuration structure. The following policies should be followed when specifying the signature of a callback:

- The first parameter should be a pointer to the object most closely associated with the callback. In the case of device drivers this would be `const struct device *dev`. For library functions it may be a pointer to another object that was referenced when the callback was provided.
- The next parameter(s) should be additional information specific to the callback invocation, such as a channel identifier, new status value, and/or a message pointer followed by the message length.
- The final parameter should be a `void *user_data` pointer carrying context that allows a shared callback function to locate additional material necessary to process the callback.

An exception to providing `user_data` as the last parameter may be allowed when the callback itself was provided through a structure that will be embedded in another structure. An example of such a case is *gpio_callback*, normally defined within a data structure specific to the code that also defines the callback function. In those cases further context can accessed by the callback indirectly by *CONTAINER_OF*.

Examples

- The requirements of *k_timer_expiry_t* invoked when a system timer alarm fires are satisfied by:

```
void handle_timeout(struct k_timer *timer)
{ ... }
```

The assumption here, as with *gpio_callback*, is that the timer is embedded in a structure reachable from *CONTAINER_OF* that can provide additional context to the callback.

- The requirements of *counter_alarm_callback_t* invoked when a counter device alarm fires are satisfied by:

```
void handle_alarm(const struct device *dev,
                  uint8_t chan_id,
                  uint32_t ticks,
                  void *user_data)
{ ... }
```

This provides more complete useful information, including which counter channel timed-out and the counter value at which the timeout occurred, as well as user context which may or may not be the *counter_alarm_cfg* used to register the callback, depending on user needs.

Conditional Data and APIs

APIs and libraries may provide features that are expensive in RAM or code size but are optional in the sense that some applications can be implemented without them. Examples of such feature include `capturing a timestamp` or `providing an alternative interface`. The developer in coordination with the community must determine whether enabling the features is to be controllable through a Kconfig option.

In the case where a feature is determined to be optional the following practices should be followed.

- Any data that is accessed only when the feature is enabled should be conditionally included via `#ifdef CONFIG_MYFEATURE` in the structure or union declaration. This reduces memory use for applications that don't need the capability.
- Function declarations that are available only when the option is enabled should be provided unconditionally. Add a note in the description that the function is available only when the specified feature is enabled, referencing the required Kconfig symbol by name. In the cases where the function is used but not enabled the definition of the function shall be excluded from compilation, so references to the unsupported API will result in a link-time error.
- Where code specific to the feature is isolated in a source file that has no other content that file should be conditionally included in `CMakeLists.txt`:

```
zephyr_sources_ifdef(CONFIG_MYFEATURE foo_funcs.c)
```

- Where code specific to the feature is part of a source file that has other content the feature-specific code should be conditionally processed using `#ifdef CONFIG_MYFEATURE`.

The Kconfig flag used to enable the feature should be added to the `PREDEFINED` variable in `doc/zephyr.doxyfile.in` to ensure the conditional API and functions appear in generated documentation.

Return Codes

Implementations of an API, for example an API for accessing a peripheral might implement only a subset of the functions that is required for minimal operation. A distinction is needed between APIs that are not supported and those that are not implemented or optional:

- APIs that are supported but not implemented shall return `-ENOSYS`.
- Optional APIs that are not supported by the hardware should be implemented and the return code in this case shall be `-ENOTSUP`.

- When an API is implemented, but the particular combination of options requested in the call cannot be satisfied by the implementation the call shall return `-ENOTSUP`. (For example, a request for a level-triggered GPIO interrupt on hardware that supports only edge-triggered interrupts)

2.6.4 API Terminology

The following terms may be used as shorthand API tags to indicate the allowed calling context (thread, ISR, pre-kernel), the effect of a call on the current thread state, and other behavioral characteristics.

reschedule
: if executing the function reaches a reschedule point

sleep
: if executing the function can cause the invoking thread to sleep

no-wait
: if a parameter to the function can prevent the invoking thread from trying to sleep

isr-ok
: if the function can be safely called and will have its specified effect whether invoked from interrupt or thread context

pre-kernel-ok
: if the function can be safely called before the kernel has been fully initialized and will have its specified effect when invoked from that context.

async
: if the function may return before the operation it initializes is complete (i.e. function return and operation completion are asynchronous)

supervisor
: if the calling thread must have supervisor privileges to execute the function

Details on the behavioral impact of each attribute are in the following sections.

reschedule

The reschedule attribute is used on a function that can reach a *reschedule point* within its execution.

Details The significance of this attribute is that when a rescheduling function is invoked by a thread it is possible for that thread to be suspended as a consequence of a higher-priority thread being made ready. Whether the suspension actually occurs depends on the operation associated with the reschedule point and the relative priorities of the invoking thread and the head of the ready queue.

Note that in the case of timeslicing, or reschedule points executed from interrupts, any thread may be suspended in any function.

Functions that are not **reschedule** may be invoked from either thread or interrupt context.

Functions that are **reschedule** may be invoked from thread context.

Functions that are **reschedule** but not **sleep** may be invoked from interrupt context.

sleep

The sleep attribute is used on a function that can cause the invoking thread to *sleep*.

Explanation This attribute is of relevance specifically when considering applications that use only non-preemptible threads, because the kernel will not replace a running cooperative-only thread at a reschedule point unless that thread has explicitly invoked an operation that caused it to sleep.

This attribute does not imply the function will sleep unconditionally, but that the operation may require an invoking thread that would have to suspend, wait, or invoke *k_yield()* before it can complete its operation. This behavior may be mediated by **no-wait**.

Functions that are **sleep** are implicitly **reschedule**.

Functions that are **sleep** may be invoked from thread context.

Functions that are **sleep** may be invoked from interrupt and pre-kernel contexts if and only if invoked in **no-wait** mode.

no-wait

The no-wait attribute is used on a function that is also **sleep** to indicate that a parameter to the function can force an execution path that will not cause the invoking thread to sleep.

Explanation The paradigmatic case of a no-wait function is a function that takes a timeout, to which *K_NO_WAIT* can be passed. The semantics of this special timeout value are to execute the function's operation as long as it can be completed immediately, and to return an error code rather than sleep if it cannot.

It is use of the no-wait feature that allows functions like *k_sem_take()* to be invoked from ISRs, since it is not permitted to sleep in interrupt context.

A function with a no-wait path does not imply that taking that path guarantees the function is synchronous.

Functions with this attribute may be invoked from interrupt and pre-kernel contexts only when the parameter selects the no-wait path.

isr-ok

The isr-ok attribute is used on a function to indicate that it works whether it is being invoked from interrupt or thread context.

Explanation Any function that is not **sleep** is inherently **isr-ok**. Functions that are **sleep** are **isr-ok** if the implementation ensures that the documented behavior is implemented even if called from an interrupt context. This may be achieved by having the implementation detect the calling context and transfer the operation that would sleep to a thread, or by documenting that when invoked from a non-thread context the function will return a specific error (generally `-EWOULDBLOCK`).

Note that a function that is **no-wait** is safe to call from interrupt context only when the no-wait path is selected. **isr-ok** functions need not provide a no-wait path.

pre-kernel-ok

The pre-kernel-ok attribute is used on a function to indicate that it works as documented even when invoked before the kernel main thread has been started.

Explanation This attribute is similar to **isr-ok** in function, but is intended for use by any API that is expected to be called in *DEVICE_DEFINE()* or SYS_INIT() calls that may be invoked with PRE_KERNEL_1 or PRE_KERNEL_2 initialization levels.

Generally a function that is **pre-kernel-ok** checks *k_is_pre_kernel()* when determining whether it can fulfill its required behavior. In many cases it would also check *k_is_in_isr()* so it can be **isr-ok** as well.

async

A function is **async** (i.e. asynchronous) if it may return before the operation it initiates has completed. An asynchronous function will generally provide a mechanism by which operation completion is reported, e.g. a callback or event.

A function that is not asynchronous is synchronous, i.e. the operation will always be complete when the function returns. As most functions are synchronous this behavior does not have a distinct attribute to identify it.

Explanation Be aware that **async** is orthogonal to context-switching. Some APIs may provide completion information through a callback, but may suspend while waiting for the resource necessary to initiate the operation; an example is *spi_transceive_signal()*.

If a function is both **no-wait** and **async** then selecting the no-wait path only guarantees that the function will not sleep. It does not affect whether the operation will be completed before the function returns.

supervisor

The supervisor attribute is relevant only in user-mode applications, and indicates that the function cannot be invoked from user mode.

2.7 Language Support

2.7.1 C Language Support

C is a general-purpose low-level programming language that is widely used for writing code for embedded systems.

Zephyr is primarily written in C and natively supports applications written in the C language. All Zephyr API functions and macros are implemented in C and available as part of the C header files under the include directory, so writing Zephyr applications in C gives the developers access to the most features.

The main() function must have the return type of int as Zephyr applications run in a "hosted" environment as defined by the C standard. Applications must return zero (0) from main. All non-zero return values are reserved.

Language Standards

Zephyr does not target a specific version of the C standards; however, the Zephyr codebase makes extensive use of the features newly introduced in the 1999 release of the ISO C standard (ISO/IEC 9899:1999, hereinafter referred to as C99) such as those listed below, effectively requiring the use of a compiler toolchain that supports the C99 standard and above:

- inline functions
- standard boolean types (`bool` in `<stdbool.h>`)
- fixed-width integer types (`[u]intN_t` in `<stdint.h>`)
- designated initializers
- variadic macros
- `restrict` qualification

Some Zephyr components make use of the features newly introduced in the 2011 release of the ISO C standard (ISO/IEC 9899:2011, hereinafter referred to as C11) such as the type-generic expressions using the `_Generic` keyword. For example, the *`cbprintf()`* component, used as the default formatted output processor for Zephyr, makes use of the C11 type-generic expressions, and this effectively requires most Zephyr applications to be compiled using a compiler toolchain that supports the C11 standard and above.

In summary, it is recommended to use a compiler toolchain that supports at least the C11 standard for developing with Zephyr. It is, however, important to note that some optional Zephyr components and external modules may make use of the C language features that have been introduced in more recent versions of the standards, in which case it will be necessary to use a more up-to-date compiler toolchain that supports such standards.

Standard Library

The C Standard Library is an integral part of any C program, and Zephyr provides the support for a number of different C libraries for the applications to choose from, depending on the compiler toolchain being used to build the application.

Common C library code Zephyr provides some C library functions that are designed to be used in conjunction with multiple C libraries. These either provide functions not available in multiple C libraries or are designed to replace functionality in the C library with code better suited for use in the Zephyr environment

Time function This provides an implementation of the standard C function, `time()`, relying on the Zephyr function, `clock_gettime()`. This function can be enabled by selecting `COMMON_LIBC_TIME`.

Dynamic Memory Management The common dynamic memory management implementation can be enabled by selecting the `CONFIG_COMMON_LIBC_MALLOC` in the application configuration file.

The common C library internally uses the *kernel memory heap API* to manage the memory heap used by the standard dynamic memory management interface functions such as `malloc()` and `free()`.

The internal memory heap is normally located in the `.bss` section. When userspace is enabled, however, it is placed in a dedicated memory partition called `z_malloc_partition`, which can be accessed from the user mode threads. The size of the internal memory heap is specified by the `CONFIG_COMMON_LIBC_MALLOC_ARENA_SIZE`.

The default heap size for applications using the common C library is zero (no heap). For other C library users, if there is an MMU present, then the default heap is 16kB. Otherwise, the heap uses all available memory.

There are also separate controls to select `calloc()` (`COMMON_LIBC_CALLOC`) and `reallocarray()` (`COMMON_LIBC_REALLOCARRAY`). Both of these are enabled by default as that doesn't impact memory usage in applications not using them.

The standard dynamic memory management interface functions implemented by the common C library are thread safe and may be simultaneously called by multiple threads. These functions are implemented in `lib/libc/common/source/stdlib/malloc.c`.

Minimal libc The most basic C library, named "minimal libc", is part of the Zephyr codebase and provides the minimal subset of the standard C library required to meet the needs of Zephyr and its subsystems, primarily in the areas of string manipulation and display.

It is very low footprint and is suitable for projects that do not rely on less frequently used portions of the ISO C standard library. It can also be used with a number of different toolchains.

The minimal libc implementation can be found in `lib/libc/minimal` in the main Zephyr tree.

Functions The minimal libc implements the minimal subset of the ISO/IEC 9899:2011 standard C library functions required to meet the needs of the Zephyr kernel, as defined by the *Coding Guidelines Rule A.4*.

Formatted Output The minimal libc does not implement its own formatted output processor; instead, it maps the C standard formatted output functions such as `printf` and `sprintf` to the *`cbprintf()`* function, which is Zephyr's own C99-compatible formatted output implementation.

For more details, refer to the *Formatted Output* OS service documentation.

Dynamic Memory Management The minimal libc uses the malloc api family implementation provided by the *common C library*, which itself is built upon the *kernel memory heap API*.

Error numbers Error numbers are used throughout Zephyr APIs to signal error conditions as return values from functions. They are typically returned as the negative value of the integer literals defined in this section, and are defined in the `errno.h` header file.

A subset of the error numbers defined in the POSIX errno.h specification and other de-facto standard sources have been added to the minimal libc.

A conscious effort is made in Zephyr to keep the values of the minimal libc error numbers consistent with the different implementations of the C standard libraries supported by Zephyr. The minimal libc `errno.h` is checked against that of the *Newlib* to ensure that the error numbers are kept aligned.

Below is a list of the error number definitions. For the actual numeric values please refer to errno.h.

group `system_errno`

System error numbers Error codes returned by functions.

Includes a list of those defined by IEEE Std 1003.1-2017.

Defines

`errno`

`EPERM`

Not owner.

`ENOENT`
: No such file or directory.

`ESRCH`
: No such context.

`EINTR`
: Interrupted system call.

`EIO`
: I/O error.

`ENXIO`
: No such device or address.

`E2BIG`
: Arg list too long.

`ENOEXEC`
: Exec format error.

`EBADF`
: Bad file number.

`ECHILD`
: No children.

`EAGAIN`
: No more contexts.

`ENOMEM`
: Not enough core.

`EACCES`
: Permission denied.

`EFAULT`
: Bad address.

`ENOTBLK`
: Block device required.

`EBUSY`
: Mount device busy.

`EEXIST`
: File exists.

`EXDEV`
: Cross-device link.

`ENODEV`
: No such device.

`ENOTDIR`
: Not a directory.

`EISDIR`
: Is a directory.

`EINVAL`
: Invalid argument.

`ENFILE`
: File table overflow.

`EMFILE`
: Too many open files.

`ENOTTY`
: Not a typewriter.

`ETXTBSY`
: Text file busy.

`EFBIG`
: File too large.

`ENOSPC`
: No space left on device.

`ESPIPE`
: Illegal seek.

`EROFS`
: Read-only file system.

`EMLINK`
: Too many links.

`EPIPE`
: Broken pipe.

`EDOM`
: Argument too large.

ERANGE
: Result too large.

ENOMSG
: Unexpected message type.

EDEADLK
: Resource deadlock avoided.

ENOLCK
: No locks available.

ENOSTR
: STREAMS device required.

ENODATA
: Missing expected message data.

ETIME
: STREAMS timeout occurred.

ENOSR
: Insufficient memory.

EPROTO
: Generic STREAMS error.

EBADMSG
: Invalid STREAMS message.

ENOSYS
: Function not implemented.

ENOTEMPTY
: Directory not empty.

ENAMETOOLONG
: File name too long.

ELOOP
: Too many levels of symbolic links.

EOPNOTSUPP
: Operation not supported on socket.

EPFNOSUPPORT
: Protocol family not supported.

ECONNRESET
: Connection reset by peer.

ENOBUFS
: No buffer space available.

EAFNOSUPPORT
: Addr family not supported.

EPROTOTYPE
: Protocol wrong type for socket.

ENOTSOCK
: Socket operation on non-socket.

ENOPROTOOPT
: Protocol not available.

ESHUTDOWN
: Can't send after socket shutdown.

ECONNREFUSED
: Connection refused.

EADDRINUSE
: Address already in use.

ECONNABORTED
: Software caused connection abort.

ENETUNREACH
: Network is unreachable.

ENETDOWN
: Network is down.

ETIMEDOUT
: Connection timed out.

EHOSTDOWN
: Host is down.

EHOSTUNREACH
: No route to host.

EINPROGRESS
: Operation now in progress.

`EALREADY`
: Operation already in progress.

`EDESTADDRREQ`
: Destination address required.

`EMSGSIZE`
: Message size.

`EPROTONOSUPPORT`
: Protocol not supported.

`ESOCKTNOSUPPORT`
: Socket type not supported.

`EADDRNOTAVAIL`
: Can't assign requested address.

`ENETRESET`
: Network dropped connection on reset.

`EISCONN`
: Socket is already connected.

`ENOTCONN`
: Socket is not connected.

`ETOOMANYREFS`
: Too many references: can't splice.

`ENOTSUP`
: Unsupported value.

`EILSEQ`
: Illegal byte sequence.

`EOVERFLOW`
: Value overflow.

`ECANCELED`
: Operation canceled.

`EWOULDBLOCK`
: Operation would block.

Newlib Newlib is a complete C library implementation written for the embedded systems. It is a separate open source project and is not included in source code form with Zephyr. Instead, the *Zephyr SDK* includes a precompiled library for each supported architecture (`libc.a` and `libm.a`).

Note

Other 3rd-party toolchains, such as *GNU Arm Embedded*, also bundle the Newlib as a precompiled library.

Zephyr implements the "API hook" functions that are invoked by the C standard library functions in the Newlib. These hook functions are implemented in `lib/libc/newlib/libc-hooks.c` and translate the library internal system calls to the equivalent Zephyr API calls.

Types of Newlib The Newlib included in the *Zephyr SDK* comes in two versions: 'full' and 'nano' variants.

Full Newlib The Newlib full variant (`libc.a` and `libm.a`) is the most capable variant of the Newlib available in the Zephyr SDK, and supports almost all standard C library features. It is optimized for performance (prefers performance over code size) and its footprint is significantly larger than the nano variant.

This variant can be enabled by selecting the `CONFIG_NEWLIB_LIBC` and de-selecting the `CONFIG_NEWLIB_LIBC_NANO` in the application configuration file.

Nano Newlib The Newlib nano variant (`libc_nano.a` and `libm_nano.a`) is the size-optimized version of the Newlib, and supports all features that the full variant supports except the new format specifiers introduced in C99, such as the `char`, `long long` type format specifiers (i.e. `%hhX` and `%llX`).

This variant can be enabled by selecting the `CONFIG_NEWLIB_LIBC` and `CONFIG_NEWLIB_LIBC_NANO` in the application configuration file.

Note that the Newlib nano variant is not available for all architectures. The availability of the nano variant is specified by the `CONFIG_HAS_NEWLIB_LIBC_NANO`.

Formatted Output Newlib supports all standard C formatted input and output functions, including `printf`, `fprintf`, `sprintf` and `sscanf`.

The Newlib formatted input and output function implementation supports all format specifiers defined by the C standard with the following exceptions:

- Floating point format specifiers (e.g. `%f`) require `CONFIG_NEWLIB_LIBC_FLOAT_PRINTF` and `CONFIG_NEWLIB_LIBC_FLOAT_SCANF` to be enabled.
- C99 format specifiers are not supported in the Newlib nano variant (i.e. `%hhX` for `char`, `%llX` for `long long`, `%jX` for `intmax_t`, `%zX` for `size_t`, `%tX` for `ptrdiff_t`).

Dynamic Memory Management Newlib implements an internal heap allocator to manage the memory blocks used by the standard dynamic memory management interface functions (for example, `malloc()` and `free()`).

The internal heap allocator implemented by the Newlib may vary across the different types of the Newlib used. For example, the heap allocator implemented in the Full Newlib (`libc.a` and `libm.a`) of the Zephyr SDK requests larger memory chunks to the operating system and has a significantly higher minimum memory requirement compared to that of the Nano Newlib (`libc_nano.a` and `libm_nano.a`).

The only interface between the Newlib dynamic memory management functions and the Zephyr-side libc hooks is the `sbrk()` function, which is used by the Newlib to manage the size of the memory pool reserved for its internal heap allocator.

The `_sbrk()` hook function, implemented in `libc-hooks.c`, handles the memory pool size change requests from the Newlib and ensures that the Newlib internal heap allocator memory pool size does not exceed the amount of available memory space by returning an error when the system is out of memory.

When userspace is enabled, the Newlib internal heap allocator memory pool is placed in a dedicated memory partition called `z_malloc_partition`, which can be accessed from the user mode threads.

The amount of memory space available for the Newlib heap depends on the system configurations:

- When MMU is enabled (`CONFIG_MMU` is selected), the amount of memory space reserved for the Newlib heap is set by the size of the free memory space returned by the *`k_mem_free_get()`* function or the `CONFIG_NEWLIB_LIBC_MAX_MAPPED_REGION_SIZE`, whichever is the smallest.
- When MPU is enabled and the MPU requires power-of-two partition size and address alignment (`CONFIG_NEWLIB_LIBC_ALIGNED_HEAP_SIZE` is set to a non-zero value), the amount of memory space reserved for the Newlib heap is set by the `CONFIG_NEWLIB_LIBC_ALIGNED_HEAP_SIZE`.
- Otherwise, the amount of memory space reserved for the Newlib heap is equal to the amount of free (unallocated) memory in the SRAM region.

The standard dynamic memory management interface functions implemented by the Newlib are thread safe and may be simultaneously called by multiple threads.

Picolibc Picolibc is a complete C library implementation written for the embedded systems, targeting C17 (ISO/IEC 9899:2018) and POSIX 2018 (IEEE Std 1003.1-2017) standards. Picolibc is an external open source project which is provided for Zephyr as a module, and included as part of the *Zephyr SDK* in precompiled form for each supported architecture (`libc.a`).

> **Note**
>
> Picolibc is also available for other 3rd-party toolchains, such as *GNU Arm Embedded*.

Zephyr implements the "API hook" functions that are invoked by the C standard library functions in the Picolibc. These hook functions are implemented in `lib/libc/picolibc/libc-hooks.c` and translate the library internal system calls to the equivalent Zephyr API calls.

Picolibc Module When built as a Zephyr module, there are several configuration knobs available to adjust the feature set in the library, balancing what the library supports versus the code size of the resulting functions. Because the standard C++ library must be compiled for the target C library, the Picolibc module cannot be used with applications which use the standard C++ library. Building the Picolibc module will increase the time it takes to compile the application.

The Picolibc module can be enabled by selecting `CONFIG_PICOLIBC_USE_MODULE` in the application configuration file.

When updating the Picolibc module to a newer version, the *toolchain-bundled Picolibc in the Zephyr SDK* must also be updated to the same version.

Toolchain Picolibc Starting with version 0.16, the Zephyr SDK includes precompiled versions of Picolibc for every target architecture, along with precompiled versions of libstdc++.

The toolchain version of Picolibc can be enabled by de-selecting `CONFIG_PICOLIBC_USE_MODULE` in the application configuration file.

For every release of Zephyr, the toolchain-bundled Picolibc and the *Picolibc module* are guaranteed to be in sync when using the *recommended version of Zephyr SDK*.

Building Without Toolchain bundled Picolibc For toolchain where there is no bundled Picolibc, it is still possible to use Picolibc by building it from source. Note that any restrictions mentioned in *Picolibc Module* still apply.

To build without toolchain bundled Picolibc, the toolchain must enable `CONFIG_PICOLIBC_SUPPORTED`. For example, this needs to be added to the toolchain Kconfig file:

```
config TOOLCHAIN_<name>_PICOLIBC_SUPPORTED
   def_bool y
   select PICOLIBC_SUPPORTED
```

By enabling `CONFIG_PICOLIBC_SUPPORTED`, the build system would automatically build Picolibc from source with its module when there is no toolchain bundled Picolibc.

Formatted Output Picolibc supports all standard C formatted input and output functions, including `printf()`, `fprintf()`, `sprintf()` and `sscanf()`.

Picolibc formatted input and output function implementation supports all format specifiers defined by the C17 and POSIX 2018 standards with the following exceptions:

- Floating point format specifiers (e.g. `%f`) require `CONFIG_PICOLIBC_IO_FLOAT`.
- Long long format specifiers (e.g. `%lld`) require `CONFIG_PICOLIBC_IO_LONG_LONG`. This option is automatically enabled with `CONFIG_PICOLIBC_IO_FLOAT`.

Printk, cbprintf and friends When using Picolibc, Zephyr formatted output functions are implemented in terms of stdio calls. This includes:

- printk, snprintk and vsnprintk
- cbprintf and cbvprintf
- fprintfcb, vfprintfcb, printfcb, vprintfcb, snprintfcb and vsnprintfcb

When using tagged args (`CONFIG_CBPRINTF_PACKAGE_SUPPORT_TAGGED_ARGUMENTS` and `CBPRINTF_PACKAGE_ARGS_ARE_TAGGED`), calls to cbpprintf will not use Picolibc, so formatting of output using those code will differ from Picolibc results as the cbprintf functions are not completely C/POSIX compliant.

Math Functions Picolibc provides full C17/IEEE STD 754-2019 support for float, double and long double math operations, except for long double versions of the Bessel functions.

Thread Local Storage Picolibc uses Thread Local Storage (TLS) (where supported) for data which is supposed to remain local to each thread, like *errno*. This means that TLS support is enabled when using Picolibc. As all TLS variables are allocated out of the thread stack area, this can affect stack size requirements by a few bytes.

C Library Local Variables Picolibc uses a few internal variables for things like heap management. These are collected in a dedicated memory partition called `z_libc_partition`. Applications using `CONFIG_USERSPACE` and memory domains must ensure that this partition is included in any domain active during Picolibc calls.

Dynamic Memory Management Picolibc uses the malloc api family implementation provided by the *common C library*, which itself is built upon the *kernel memory heap API*.

Formatted Output

C defines standard formatted output functions such as `printf` and `sprintf` and these functions are implemented by the C standard libraries.

Each C standard library has its own set of requirements and configurations for selecting the formatted output modes and capabilities. Refer to each C standard library documentation for more details.

Dynamic Memory Management

C defines a standard dynamic memory management interface (for example, `malloc()` and `free()`) and these functions are implemented by the C standard libraries.

While the details of the dynamic memory management implementation varies across different C standard libraries, all supported libraries must conform to the following conventions. Every supported C standard library shall:

- manage its own memory heap either internally or by invoking the hook functions (for example, `sbrk()`) implemented in `libc-hooks.c`.
- maintain the architecture- and memory region-specific alignment requirements for the memory blocks allocated by the standard dynamic memory allocation interface (for example, `malloc()`).
- allocate memory blocks inside the `z_malloc_partition` memory partition when userspace is enabled. See *Pre-defined Memory Partitions*.

For more details regarding the C standard library-specific memory management implementation, refer to each C standard library documentation.

> **Note**
>
> Native Zephyr applications should use the *memory management API* supported by the Zephyr kernel such as *`k_malloc()`* in order to take advantage of the advanced features that they offer.
>
> C standard dynamic memory management interface functions such as `malloc()` should be used only by the portable applications and libraries that target multiple operating systems.

2.7.2 C++ Language Support

C++ is a general-purpose object-oriented programming language that is based on the C language.

Enabling C++ Support

Zephyr supports applications written in both C and C++. However, to use C++ in an application you must configure Zephyr to include C++ support by selecting the `CONFIG_CPP` in the application configuration file.

To enable C++ support, the compiler toolchain must also include a C++ compiler and the included compiler must be supported by the Zephyr build system. The *Zephyr SDK*, which includes the GNU C++ Compiler (part of GCC), is supported by Zephyr, and the features and their availability documented here assume the use of the Zephyr SDK.

The default C++ standard level (i.e. the language enforced by the compiler flags passed) for Zephyr apps is C++11. Other standards are available via kconfig choice, for example `CONFIG_STD_CPP98`. The oldest standard supported and tested in Zephyr is C++98.

When compiling a source file, the build system selects the C++ compiler based on the suffix (extension) of the files. Files identified with either a **cpp** or a **cxx** suffix are compiled using the C++ compiler. For example, `myCplusplusApp.cpp` is compiled using C++.

The C++ standard requires the `main()` function to have the return type of `int`. Your `main()` must be defined as `int main(void)`. Zephyr ignores the return value from main, so applications should not return status information and should, instead, return zero.

Note

Do not use C++ for kernel, driver, or system initialization code.

Language Features

Zephyr currently provides only a subset of C++ functionality. The following features are *not* supported:

- Static global object destruction
- OS-specific C++ standard library classes (e.g. `std::thread`, `std::mutex`)

While not an exhaustive list, support for the following functionality is included:

- Inheritance
- Virtual functions
- Virtual tables
- Static global object constructors
- Dynamic object management with the **new** and **delete** operators
- Exceptions
- RTTI (runtime type information)
- Standard Template Library (STL)

Static global object constructors are initialized after the drivers are initialized but before the application `main()` function. Therefore, use of C++ is restricted to application code.

In order to make use of the C++ exceptions, the `CONFIG_CPP_EXCEPTIONS` must be selected in the application configuration file.

Zephyr Minimal C++ Library

Zephyr minimal C++ library (`lib/cpp/minimal`) provides a minimal subset of the C++ standard library and application binary interface (ABI) functions to enable basic C++ language support. This includes:

- `new` and `delete` operators
- virtual function stub and vtables
- static global initializers for global constructors

The scope of the minimal C++ library is strictly limited to providing the basic C++ language support, and it does not implement any Standard Template Library (STL) classes and functions. For

this reason, it is only suitable for use in the applications that implement their own (non-standard) class library and do not rely on the Standard Template Library (STL) components.

Any application that makes use of the Standard Template Library (STL) components, such as `std::string` and `std::vector`, must enable the C++ standard library support.

C++ Standard Library

The C++ Standard Library is a collection of classes and functions that are part of the ISO C++ standard (`std` namespace).

Zephyr does not include any C++ standard library implementation in source code form. Instead, it allows configuring the build system to link against the pre-built C++ standard library included in the C++ compiler toolchain.

To enable C++ standard library, select an applicable toolchain-specific C++ standard library type from the `CONFIG_LIBCPP_IMPLEMENTATION` in the application configuration file.

For instance, when building with the *Zephyr SDK*, the build system can be configured to link against the GNU C++ Library (`libstdc++.a`), which is a fully featured C++ standard library that provides all features required by the ISO C++ standard including the Standard Template Library (STL), by selecting `CONFIG_GLIBCXX_LIBCPP` in the application configuration file.

The following C++ standard libraries are supported by Zephyr:

- GNU C++ Library (`CONFIG_GLIBCXX_LIBCPP`)
- ARC MetaWare C++ Library (`CONFIG_ARCMWDT_LIBCPP`)

A Zephyr subsystem that requires the features from the full C++ standard library can select, from its config, `CONFIG_REQUIRES_FULL_LIBCPP`, which automatically selects a compatible C++ standard library unless the Kconfig symbol for a specific C++ standard library is selected.

Header files and incompatibilities between C and C++

To interact with each other, C and C++ must share code through header files: data structures, macros, static functions,... While C and C++ have a large overlap, they're different languages with known incompatibilities. C is not just a C++ subset. Standard levels (e.g.: "C+11") add another level of complexity as new features are often inspired by and copied from the other language but many years later and with subtle differences. Making things more complex, compilers often offer early prototypes of features before they become standardized. Standards can have ambiguities interpreted differently by different compilers. Compilers can have bugs and these may need workarounds. To help with this, many projects restrict themselves to a limited number of toolchains. Zephyr does not.

These compatibility issues affect header files dis-proportionally. Not just because they have to be compatible between C and C++, but also because they end up being compiled in a surprisingly high number of other source files due to *indirect* inclusion and the lack of structure and headers organization that is typical in real-world projects. So, header files are exposed to a much larger variety of toolchains and project configurations. Adding more constraints, the Zephyr project has demanding policies with respect to code style, compiler warnings, static analyzers and standard compliance (e.g.: MISRA).

Put together, all these constraints can make writing header files very challenging. The purpose of this section is to document some best "header practices" and lessons learned in a Zephyr-specific context. While a lot of the information here is not Zephyr-specific, this section is not a substitute for knowledge of C/C++ standards, textbooks and other references.

Testing Fortunately, the Zephyr project has an extensive test and CI infrastructure that provides coverage baselines, catches issues early, enforces policies and maintains such combinatorial explosions under some control. The `tests/lib/cpp/cxx/` are very useful in this context because their `testcase.yaml` configuration lets `twister` iterate quickly over a range of `-std` parameters: `-std=c++98`, `-std=c++11`, etc.

Keep in mind unused macros are not compiled.

Designated initializers Initialization macros are common in header files as they help reduce boilerplate code. C99 added initialization of `struct` and `union` types by "designated" member names instead of a list of *bare* expressions. Some GCC versions support designated initializers even in their C90 mode.

When used at a simple level, designated initializers are less error-prone, more readable and more flexible. On the other hand, C99 allowed a surprisingly large and lax set of possibilities: designated initializers can be out of order, duplicated, "nested" (`.a.x =`), various other braces can be omitted, designated initializers and not can be mixed, etc.

Twenty years later, C++20 added designated initializers to C++ but in much more restricted way; partly because a C++ `struct` is actually a `class`. As described in the C++ proposal number P0329 (which compares with C) or in any complete C++ reference, a mix is not allowed and initializers must be in order (gaps are allowed).

Interestingly, the new restrictions in C++20 can cause `gcc -std=c++20` to fail to compile code that successfully compiles with `gcc -std=c++17`. For example, `gcc -std=c++17` and older allow the C-style mix of initializers and bare expressions. This fails to compile with using `gcc -std=c++20` *with the same GCC version*.

Recommendation: to maximize compatibility across different C and C++ toolchains and standards, designated initializers in Zephyr header files should follow all C++20 rules and restrictions. Non-designated, pre-C99 initialization offers more compatibility and is also allowed but designated initialization is the more readable and preferred code style. In any case, both styles must never be mixed in the same initializer.

Warning: successful compilation is not the end of the incompatibility story. For instance, the *evaluation order* of initializer expressions is unspecified in C99! It is the (expected) left-to-right order in C++20. Other standard revisions may vary. In doubt, do not rely on evaluation order (here and elsewhere).

Anonymous unions Anonymous unions (a.k.a. "unnamed" unions) seem to have been part of C++ from its very beginning. They were not officially added to C until C11. As usual, there are differences between C and C++. For instance, C supports anonymous unions only as a member of an enclosing `struct` or `union`, empty lists `{ }` have always been allowed in C++ but they require C23, etc.

When initializing anonymous members, the expression can be enclosed in braces or not. It can be either designated or bare. For maximum portability, when initializing *anonymous unions*:

- Do *not* enclose *designated* initializers with braces. This is required by C++20 and above which perceive such braces as mixing bare expressions with (other) designated initializers and fails to compile.
- Do enclose *bare* expressions with braces. This is required by C. Maybe because C is laxer and allows many initialization possibilities and variations, so it may need such braces to disambiguate? Note C does allow omitting most braces in initializer expressions - but not in this particular case of initializing anonymous unions with bare expressions.

Some pre-C11 GCC versions support some form of anonymous unions. They unfortunately require enclosing their designated initializers with braces which conflicts with this recommendation. This can be solved with an `#ifdef __STDC_VERSION__` as demonstrated in Zephyr commit c15f029a7108 and the corresponding code review.

2.8 Optimizations

Guides on how to optimize Zephyr for performance, power and footprint.

2.8.1 Optimizing for Footprint

Stack Sizes

Stack sizes of various system threads are specified generously to allow for usage in different scenarios on as many supported platforms as possible. You should start the optimization process by reviewing all stack sizes and adjusting them for your application:

`CONFIG_ISR_STACK_SIZE`
: Set to 2048 by default

`CONFIG_MAIN_STACK_SIZE`
: Set to 1024 by default

`CONFIG_IDLE_STACK_SIZE`
: Set to 320 by default

`CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE`
: Set to 1024 by default

`CONFIG_PRIVILEGED_STACK_SIZE`
: Set to 1024 by default, depends on userspace feature.

Unused Peripherals

Some peripherals are enabled by default. You can disable unused peripherals in your project configuration, for example:

```
CONFIG_GPIO=n
CONFIG_SPI=n
```

Various Debug/Informational Options

The following options are enabled by default to provide more information about the running application and to provide means for debugging and error handling:

`CONFIG_BOOT_BANNER`
: This option can be disabled to save a few bytes.

`CONFIG_DEBUG`
: This option can be disabled for production builds

MPU/MMU Support

Depending on your application and platform needs, you can disable MPU/MMU support to gain some memory and improve performance. Consider the consequences of this configuration choice though, because you'll lose advanced stack checking and support.

2.8.2 Optimization Tools

The available optimization tools let you analyse *Footprint and Memory Usage* and *Data Structures* using different build system targets.

Footprint and Memory Usage

The build system offers 3 targets to view and analyse RAM, ROM and stack usage in generated images. The tools run on the final image and give information about size of symbols and code being used in both RAM and ROM. Additionally, with features available through the compiler, we can also generate worst-case stack usage analysis.

Some of the tools mentioned in this section are organizing their output based on the physical organization of the symbols. As some symbols might be external to the project's tree structure, or might lack metadata needed to display them by name, the following top-level containers are used to group such symbols:

- Hidden - The RAM and ROM reports list all processing symbols with no matching mapped files in the Hidden category.

  This means that the file for the listed symbol was not added to the metadata file, was empty, or was undefined. The tool was unable to get the name of the function for the given symbol nor identify where it comes from.

- No paths - The RAM and ROM reports list all processing symbols with relative paths in the No paths category.

  This means that the listed symbols cannot be placed in the tree structure of the report at an absolute path under one specific file. The tool was able to get the name of the function, but it was unable to identify where it comes from.

> **Note**
>
> You can have multiple cases of the same function, and the No paths category will list the sum of these in one entry.

Build Target: ram_report List all compiled objects and their RAM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the `ram_report` target with your board, as in the following example.

Using west:

```
west build -b reel_board samples/hello_world
west build -t ram_report
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild ram_report
```

These commands will generate something similar to the output below:

```
Path                                                                                  Size    %      Address
=======================================================================================================
Root                                                                                  4637 100.00%  -
├── (hidden)                                                                             4   0.09%  -
├── (no paths)                                                                        2748  59.26%  -
|   ├── _cpus_active                                                                    4   0.09%  0x20000314
|   ├── _kernel                                                                        32   0.69%  0x20000318
|   ├── _sw_isr_table                                                                 384   8.28%  0x00006474
|   ├── cli.1                                                                          16   0.35%  0x20000254
|   ├── on.2                                                                            4   0.09%  0x20000264
|   ├── poll_out_lock.0                                                                4   0.09%  0x200002d4
|   ├── z_idle_threads                                                               128   2.76%  0x20000120
|   ├── z_interrupt_stacks                                                          2048  44.17%  0x20000360
|   └── z_main_thread                                                                128   2.76%  0x200001a0
├── WORKSPACE                                                                        184   3.97%  -
|   └── modules                                                                      184   3.97%  -
|       └── hal                                                                      184   3.97%  -
|           └── nordic                                                               184   3.97%  -
|               └── nrfx                                                             184   3.97%  -
|                   └── drivers                                                      184   3.97%  -
|                       └── src                                                      184   3.97%  -

```

Build Target: rom_report List all compiled objects and their ROM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the `rom_report` target with your board, as in the following example.

Using west:

```
west build -b reel_board samples/hello_world
west build -t rom_report
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild rom_report
```

These commands will generate something similar to the output below:

```
Path                                                                                  Size    %      Address

```

Build Target: puncover This target uses a third-party tool called puncover which can be found at https://github.com/HBehrens/puncover. When this target is built, it will launch a local web server which will allow you to open a web client and browse the files and view their ROM, RAM, and stack usage.

Before you can use this target, install the puncover Python module:

```
pip3 install git+https://github.com/HBehrens/puncover --user
```

Warning

This is a third-party tool that might or might not be working at any given time. Please check the GitHub issues, and report new problems to the project maintainer.

After you installed the Python module, use `puncover` target with your board, as in the following example.

Using west:

```
west build -b reel_board samples/hello_world
west build -t puncover
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild puncover
```

To view worst-case stack usage analysis, build this with the `CONFIG_STACK_USAGE` enabled.

Using west:

```
west build -b reel_board samples/hello_world -- -DCONFIG_STACK_USAGE=y
west build -t puncover
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board -DCONFIG_STACK_USAGE=y samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild puncover
```

Data Structures

Build Target: pahole Poke-a-hole (pahole) is an object-file analysis tool to find the size of the data structures, and the holes caused due to aligning the data elements to the word-size of the CPU by the compiler.

Poke-a-hole (pahole) must be installed prior to using this target. It can be obtained from https://git.kernel.org/pub/scm/devel/pahole/pahole.git and is available in the dwarves package in both fedora and ubuntu:

```
sudo apt-get install dwarves
```

Alternatively, you can get it from fedora:

```
sudo dnf install dwarves
```

After you installed the package, use `pahole` target with your board, as in the following example.

Using west:

```
west build -b reel_board samples/hello_world
west build -t pahole
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild pahole
```

Pahole will generate something similar to the output below in the console:

```
/* Used at: [...]/build/zephyr/kobject_hash.c */
/* <375> [...]/zephyr/include/zephyr/sys/dlist.h:37 */
union {
        struct _dnode *            head;               /*     0     4 */
        struct _dnode *            next;               /*     0     4 */
};
/* Used at: [...]/build/zephyr/kobject_hash.c */
```

(continues on next page)

(continued from previous page)

```
/* <397> [...]/zephyr/include/zephyr/sys/dlist.h:36 */
struct _dnode {
        union {
                struct _dnode *    head;                /*     0     4 */
                struct _dnode *    next;                /*     0     4 */
        };                                              /*     0     4 */
        union {
                struct _dnode *    tail;                /*     4     4 */
                struct _dnode *    prev;                /*     4     4 */
        };                                              /*     4     4 */

        /* size: 8, cachelines: 1, members: 2 */
        /* last cacheline: 8 bytes */
};
/* Used at: [...]/build/zephyr/kobject_hash.c */
/* <3b7> [...]/zephyr/include/zephyr/sys/dlist.h:41 */
union {
        struct _dnode *            tail;               /*     0     4 */
        struct _dnode *            prev;               /*     0     4 */
};
...
...
```

2.9 Flashing and Hardware Debugging

2.9.1 Flash & Debug Host Tools

This guide describes the software tools you can run on your host workstation to flash and debug Zephyr applications.

Zephyr's west tool has built-in support for all of these in its `flash`, `debug`, `debugserver`, and `attach` commands, provided your board hardware supports them and your Zephyr board directory's `board.cmake` file declares that support properly. See *Building, Flashing and Debugging* for more information on these commands.

SAM Boot Assistant (SAM-BA)

Atmel SAM Boot Assistant (Atmel SAM-BA) allows In-System Programming (ISP) from USB or UART host without any external programming interface. Zephyr allows users to develop and program boards with SAM-BA support using *west*. Zephyr supports devices with/without ROM bootloader and both extensions from Arduino and Adafruit. Full support was introduced in Zephyr SDK 0.12.0.

The typical command to flash the board is:

```
west flash [ -r bossac ] [ -p /dev/ttyX ]
```

Flash configuration for devices:

With ROM bootloader

These devices don't need any special configuration. After building your application, just run `west flash` to flash the board.

Without ROM bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see *Flash map* for details.
2. Have board `.defconfig` file with the `CONFIG_USE_DT_CODE_PARTITION` Kconfig option set to `y` to instruct the build system to use these partitions for code relocation. This option can also be set in `prj.conf` or any other Kconfig fragment.
3. Build and flash the SAM-BA bootloader on the device.

With compatible SAM-BA bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see *Flash map* for details.
2. Have board `.defconfig` file with the `CONFIG_BOOTLOADER_BOSSA` Kconfig option set to `y`. This will automatically select the `CONFIG_USE_DT_CODE_PARTITION` Kconfig option which instruct the build system to use these partitions for code relocation. The board `.defconfig` file should have `CONFIG_BOOTLOADER_BOSSA_ARDUINO` , `CONFIG_BOOTLOADER_BOSSA_ADAFRUIT_UF2` or the `CONFIG_BOOTLOADER_BOSSA_LEGACY` Kconfig option set to `y` to select the right compatible SAM-BA bootloader mode. These options can also be set in `prj.conf` or any other Kconfig fragment.
3. Build and flash the SAM-BA bootloader on the device.

Note

The `CONFIG_BOOTLOADER_BOSSA_LEGACY` Kconfig option should be used as last resource. Try configure first with Devices without ROM bootloader.

Typical flash layout and configuration For bootloaders that reside on flash, the devicetree partition layout is mandatory. For devices that have a ROM bootloader, they are mandatory when the application uses a storage or other non-application partition. In this special case, the boot partition should be omitted and code_partition should start from offset 0. It is necessary to define the partitions with sizes that avoid overlaps, always.

A typical flash layout for devices without a ROM bootloader is:

```
/ {
        chosen {
                zephyr,code-partition = &code_partition;
        };
};

&flash0 {
        partitions {
                compatible = "fixed-partitions";
                #address-cells = <1>;
                #size-cells = <1>;

                boot_partition: partition@0 {
                        label = "sam-ba";
                        reg = <0x00000000 0x2000>;
                        read-only;
                };

                code_partition: partition@2000 {
                        label = "code";
                        reg = <0x2000 0x3a000>;
                        read-only;
```

(continues on next page)

(continued from previous page)

```
                };

                /*
                * The final 16 KiB is reserved for the application.
                * Storage partition will be used by FCB/LittleFS/NVS
                * if enabled.
                */
                storage_partition: partition@3c000 {
                        label = "storage";
                        reg = <0x0003c000 0x00004000>;
                };
        };
};
```

A typical flash layout for devices with a ROM bootloader and storage partition is:

```
/ {
        chosen {
                zephyr,code-partition = &code_partition;
        };
};

&flash0 {
        partitions {
                compatible = "fixed-partitions";
                #address-cells = <1>;
                #size-cells = <1>;

                code_partition: partition@0 {
                        label = "code";
                        reg = <0x0 0xF0000>;
                        read-only;
                };

                /*
                * The final 64 KiB is reserved for the application.
                * Storage partition will be used by FCB/LittleFS/NVS
                * if enabled.
                */
                storage_partition: partition@F0000 {
                        label = "storage";
                        reg = <0x000F0000 0x00100000>;
                };
        };
};
```

Enabling SAM-BA runner In order to instruct Zephyr west tool to use the SAM-BA bootloader the `board.cmake` file must have `include(${ZEPHYR_BASE}/boards/common/bossac.board.cmake)` entry. Note that Zephyr tool accept more entries to define multiple runners. By default, the first one will be selected when using `west flash` command. The remaining options are available passing the runner option, for instance `west flash -r bossac`.

More implementation details can be found in the boards documentation. As a quick reference, see these three board documentation pages:

- sam4e_xpro (ROM bootloader)
- adafruit_feather_m0_basic_proto (Adafruit UF2 bootloader)
- arduino_nano_33_iot (Arduino bootloader)
- arduino_nano_33_ble (Arduino legacy bootloader)

Enabling BOSSAC on Windows Native [Experimental] Zephyr SDK´s bossac is currently supported on Linux and macOS only. Windows support can be achieved by using the bossac version from BOSSA official releases. After installing using default options, the `bossac.exe` must be added to Windows PATH. A specific bossac executable can be used by passing the `--bossac` option, as follows:

```
west flash -r bossac --bossac="C:\Program Files (x86)\BOSSA\bossac.exe" --bossac-port="COMx"
```

Note

WSL is not currently supported.

LinkServer Debug Host Tools

Linkserver is a utility for launching and managing GDB servers for NXP debug probes, which also provides a command-line target flash programming capabilities. Linkserver can be used with the NXP MCUXpresso for Visual Studio Code implementation, with custom debug configurations based on GNU tools or as part of a headless solution for continuous integration and test. LinkServer can be used with MCU-Link, LPC-Link2, LPC11U35-based and OpenSDA based standalone or on-board debug probes from NXP.

NXP recommends installing LinkServer by using NXP's MCUXpresso Installer. This method will also install the tools supporting the debug probes below, including NXP's MCU-Link and LPC-Scrypt tools.

LinkServer is compatible with the following debug probes:

- *LPC-LINK2 CMSIS DAP Onboard Debug Probe*
- *MCU-Link CMSIS-DAP Onboard Debug Probe*
- *OpenSDA DAPLink Onboard Debug Probe*

To use LinkServer with West commands, the install folder should be added to the *PATH environment variable*. The default installation path to add is:

Linux

```
/usr/local/LinkServer
```

Windows

```
c:\nxp\LinkServer_<version>
```

Supported west commands:

1. flash
2. debug
3. debugserver
4. attach

Notes:

1. Probes can be listed with LinkServer:

```
LinkServer probes
```

2. With multiple debug probes attached to the host, use the LinkServer west runner `--probe` option to pass the probe index.

```
west flash --runner=linkserver --probe=3
```

3. Device-specific settings can be overridden with the west runner for LinkServer with the option '–override'. May be used multiple times. The format is dictated by LinkServer, e.g.:

```
west flash --runner=linkserver --override /device/memory/5/flash-driver=MIMXRT500_SFDP_MXIC_
↪OSPI_S.cfx
```

4. LinkServer does not install an implicit breakpoint at the reset handler. If you would like to single step from the start of their application, you will need to add a breakpoint at `main` or the reset handler manually.

J-Link Debug Host Tools

Segger provides a suite of debug host tools for Linux, macOS, and Windows operating systems:

- J-Link GDB Server: GDB remote debugging
- J-Link Commander: Command-line control and flash programming
- RTT Viewer: RTT terminal input and output
- SystemView: Real-time event visualization and recording

These debug host tools are compatible with the following debug probes:

- *LPC-Link2 J-Link Onboard Debug Probe*
- *OpenSDA J-Link Onboard Debug Probe*
- *MCU-Link JLink Onboard Debug Probe*
- *J-Link External Debug Probe*
- *ST-LINK/V2-1 Onboard Debug Probe*

Check if your SoC is listed in J-Link Supported Devices.

Download and install the J-Link Software and Documentation Pack to get the J-Link GDB Server and Commander, and to install the associated USB device drivers. RTT Viewer and SystemView can be downloaded separately, but are not required.

Note that the J-Link GDB server does not yet support Zephyr RTOS-awareness.

OpenOCD Debug Host Tools

OpenOCD is a community open source project that provides GDB remote debugging and flash programming support for a wide range of SoCs. A fork that adds Zephyr RTOS-awareness is included in the Zephyr SDK; otherwise see Getting OpenOCD for options to download OpenOCD from official repositories.

These debug host tools are compatible with the following debug probes:

- *OpenSDA DAPLink Onboard Debug Probe*
- *J-Link External Debug Probe*
- *ST-LINK/V2-1 Onboard Debug Probe*

Check if your SoC is listed in OpenOCD Supported Devices.

Note

On Linux, openocd is available though the Zephyr SDK. Windows users should use the following steps to install openocd:

- Download openocd for Windows from here: OpenOCD Windows
- Copy bin and share dirs to `C:\Program Files\OpenOCD\`
- Add `C:\Program Files\OpenOCD\bin` to 'PATH' environment variable

pyOCD Debug Host Tools

pyOCD is an open source project from Arm that provides GDB remote debugging and flash programming support for Arm Cortex-M SoCs. It is distributed on PyPi and installed when you complete the *Get Zephyr and install Python dependencies* step in the Getting Started Guide. pyOCD includes support for Zephyr RTOS-awareness.

These debug host tools are compatible with the following debug probes:

- *LPC-LINK2 CMSIS DAP Onboard Debug Probe*
- *MCU-Link CMSIS-DAP Onboard Debug Probe*
- *OpenSDA DAPLink Onboard Debug Probe*
- *ST-LINK/V2-1 Onboard Debug Probe*

Check if your SoC is listed in pyOCD Supported Devices.

Lauterbach TRACE32 Debug Host Tools

Lauterbach TRACE32 is a product line of microprocessor development tools, debuggers and real-time tracer with support for JTAG, SWD, NEXUS or ETM over multiple core architectures, including Arm Cortex-A/-R/-M, RISC-V, Xtensa, etc. Zephyr allows users to develop and program boards with Lauterbach TRACE32 support using *west*.

The runner consists of a wrapper around TRACE32 software, and allows a Zephyr board to execute a custom start-up script (Practice Script) for the different commands supported, including the ability to pass extra arguments from CMake. Is up to the board using this runner to define the actions performed on each command.

Install Lauterbach TRACE32 Software Download Lauterbach TRACE32 software from the Lauterbach TRACE32 download website (registration required) and follow the installation steps described in Lauterbach TRACE32 Installation Guide.

Flashing and Debugging Set the *environment variable* `T32_DIR` to the TRACE32 system directory. Then execute `west flash` or `west debug` commands to flash or debug the Zephyr application as detailed in *Building, Flashing and Debugging*. The `debug` command launches TRACE32 GUI to allow debug the Zephyr application, while the `flash` command hides the GUI and perform all operations in the background.

By default, the `t32` runner will launch TRACE32 using the default configuration file named `config.t32` located in the TRACE32 system directory. To use a different configuration file, supply the argument `--config CONFIG` to the runner, for example:

```
west flash --config myconfig.t32
```

For more options, run `west flash --context -r t32` to print the usage.

Zephyr RTOS Awareness To enable Zephyr RTOS awareness follow the steps described in Lauterbach TRACE32 Zephyr OS Awareness Manual.

NXP S32 Debug Probe Host Tools

NXP S32 Debug Probe is designed to work in conjunction with NXP S32 Design Studio for S32 Platform.

Download (registration required) NXP S32 Design Studio for S32 Platform and follow the S32 Design Studio for S32 Platform Installation User Guide to get the necessary debug host tools and associated USB device drivers.

Note that Zephyr RTOS-awareness support for the NXP S32 GDB server depends on the target device. Consult the product release notes for more information.

Supported west commands:

1. debug
2. debugserver
3. attach

Basic usage Before starting, add NXP S32 Design Studio installation directory to the system *PATH environment variable*. Alternatively, it can be passed to the runner on each invocation via `--s32ds-path` as shown below:

Linux

```
west debug --s32ds-path=/opt/NXP/S32DS.3.5
```

Windows

```
west debug --s32ds-path=C:\NXP\S32DS.3.5
```

If multiple S32 debug probes are connected to the host via USB, the runner will ask the user to select one via command line prompt before continuing. The connection string for the probe can be also specified when invoking the runner via `--dev-id=<connection-string>`. Consult NXP S32 debug probe user manual for details on how to construct the connection string. For example, if using a probe with serial ID `00:04:9f:00:ca:fe`:

```
west debug --dev-id='s32dbg:00:04:9f:00:ca:fe'
```

It is possible to pass extra options to the debug host tools via `--tool-opt`. When executing `debug` or `attach` commands, the tool options will be passed to the GDB client only. When executing `debugserver`, the tool options will be passed to the GDB server. For example, to load a Zephyr application to SRAM and afterwards detach the debug session:

```
west debug --tool-opt='--batch'
```

probe-rs Debug Host Tools

probe-rs is an open-source embedded toolkit written in Rust. It provides out-of-the-box support for a variety of debug probes, including CMSIS-DAP, ST-Link, SEGGER J-Link, FTDI and built-in USB-JTAG interface on ESP32 devices.

Check probe-rs Installation for more setup details.

Check if your SoC is listed in probe-rs Supported Devices.

2.9.2 Debug Probes

A *debug probe* is special hardware which allows you to control execution of a Zephyr application running on a separate board. Debug probes usually allow reading and writing registers and memory, and support breakpoint debugging of the Zephyr application on your host workstation using tools like GDB. They may also support other debug software and more advanced features such as *tracing program execution*. For details on the related host software supported by Zephyr, see *Flash & Debug Host Tools*.

Debug probes are usually connected to your host workstation via USB; they are sometimes also accessible via an IP network or other means. They usually connect to the device running Zephyr using the JTAG or SWD protocols. Debug probes are either separate hardware devices or circuitry integrated into the same board which runs Zephyr.

Many supported boards in Zephyr include a second microcontroller that serves as an onboard debug probe, usb-to-serial adapter, and sometimes a drag-and-drop flash programmer. This eliminates the need to purchase an external debug probe and provides a variety of debug host tool options.

Several hardware vendors have their own branded onboard debug probe implementations: NXP boards may use *OpenSDA*, *LPC-Link2*, or *MCU-Link*, probes depending on the microcontroller the debug probe firmware runs on. ST boards have the *ST-LINK probe*. Each onboard debug probe microcontroller can support one or more types of firmware that communicate with their respective debug host tools. For example, an OpenSDA microcontroller can be programmed with DAPLink firmware to communicate with pyOCD or OpenOCD debug host tools, or with J-Link firmware to communicate with J-Link debug host tools.

Debug Probes & Host Tools Compatibility Chart		Host Tools				
		J-Link Debug	**OpenOCD**	**pyOCD**	**NXP S32DS**	**NXP LinkServer**
Debug Probes	**J-Link External**	✓	✓			
	LPC-Link2 CMSIS-DAP					✓
	LPC-Link2 J-Link	✓				
	MCU-Link CMSIS-DAP					✓
	MCU-Link J-Link	✓				
	NXP S32 Debug Probe				✓	
	OpenSDA DAPLink		✓	✓		✓
	OpenSDA J-Link	✓				
	ST-LINK/V2-1	✓	✓	*some STM32 boards*		

Some supported boards in Zephyr do not include an onboard debug probe and therefore require an external debug probe. In addition, boards that do include an onboard debug probe often also have an SWD or JTAG header to enable the use of an external debug probe instead. One reason

this may be useful is that the onboard debug probe may have limitations, such as lack of support for advanced debuggers or high-speed tracing. You may need to adjust jumpers to prevent the onboard debug probe from interfering with the external debug probe.

NXP Onboard Debug Probes

NXP boards may have one of several onboard debug probes. These probes include the *MCU-Link Onboard Debug Probe*, *LPC-LINK2 Onboard Debug Probe* and *OpenSDA Onboard Debug Probe*. Each of these probes is implemented as a secondary microcontroller present on the evaluation board. The specific debug probe type present on a given board can be determined based on the debug microcontroller SOC:

- LPC55S69: *MCU-Link Onboard Debug Probe*
- LPC4322: *LPC-LINK2 Onboard Debug Probe*
- MK20: *OpenSDA Onboard Debug Probe*

For example, the frdm_k64f board has an MK20 debug microcontroller, so this board uses the *OpenSDA Onboard Debug Probe*.

MCU-Link Onboard Debug Probe

The MCU-Link onboard debug probe uses an LPC55S69 SOC. This probe supports the following firmwares:

- *MCU-Link CMSIS-DAP Onboard Debug Probe* (default firmware)
- *MCU-Link JLink Onboard Debug Probe*

This probe is programmed using the MCU-Link host tools, which are installed with the *LinkServer Debug Host Tools*. NXP recommends using NXP's MCUXpresso Installer to install the Linkserver tools.

MCU-Link CMSIS-DAP Onboard Debug Probe This is the default firmware installed on MCU-Link debug probes. The CMSIS-DAP debug probes allow debugging from any compatible toolchain, including IAR EWARM, Keil MDK, NXP's MCUXpresso IDE and MCUXpresso extension for VS Code. In addition to debug probe functionality, the MCU-Link probes may also provide:

1. SWO trace end point: this virtual device is used by MCUXpresso to retrieve SWO trace data. See the MCUXpresso IDE documentation for more information.
2. Virtual COM (VCOM) port / UART bridge connected to the target processor
3. USB to UART, SPI and/or I2C interfaces (depending on MCU-Link type/implementation)
4. Energy measurements of the target MCU

This debug probe is compatible with the following debug host tools:

- *LinkServer Debug Host Tools*

Once the MCU-Link host tools are installed, the following steps are required to program the CMSIS-DAP firmware:

1. Make sure the MCU-Link utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the MCU-Link microcontroller into DFU boot mode by attaching the DFU jumper then connecting to the USB debug port on the board. This jumper may also be referred to as the ISP jumper, and will be connected to `PIO0_5` on the LPC55S69.
3. Run the `program_CMSIS` script, found in the installed MCU-Link `scripts` folder.

4. Remove the DFU jumper and power cycle the board.

MCU-Link JLink Onboard Debug Probe This debug probe firmware provides a JLink compatible debug interface, as well as a USB-Serial adapter. It is compatible with the following debug host tools:

- *J-Link Debug Host Tools*

These probes do not have JLink firmware installed by default, and must be updated. Once the MCU-Link host tools are installed, the following steps are required to program the JLink firmware:

1. Make sure the MCU-Link utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the MCU-Link microcontroller into DFU boot mode by attaching the DFU jumper then connecting to the USB debug port on the board. This jumper may also be referred to as the ISP jumper, and will be connected to `PIO0_5` on the LPC55S69.
3. Run the `program_JLINK` script, found in the installed MCU-Link `scripts` folder.
4. Remove the DFU jumper and power cycle the board.

LPC-LINK2 Onboard Debug Probe

The LPC-LINK2 onboard debug probe uses an LPC4322 SOC. This probe supports the following firmwares:

- *LPC-LINK2 CMSIS DAP Onboard Debug Probe*
- *LPC-Link2 J-Link Onboard Debug Probe*
- *LPC-Link2 DAPLink Onboard Debug Probe* (default firmware)

This probe is programmed using the LPCScrypt host tools, which are installed with the *LinkServer Debug Host Tools*. NXP recommends using NXP's MCUXpresso Installer to install the Linkserver tools.

LPC-LINK2 CMSIS DAP Onboard Debug Probe The CMSIS-DAP debug probes allow debugging from any compatible toolchain, including IAR EWARM, Keil MDK, as well as NXP's MCUXpresso IDE and MCUXpresso extension for VS Code. As well as providing debug probe functionality, the LPC-Link2 probes also provide:

1. SWO trace end point: this virtual device is used by MCUXpresso to retrieve SWO trace data. See the MCUXpresso IDE documentation for more information.
2. Virtual COM (VCOM) port / UART bridge connected to the target processor
3. LPCSIO bridge that provides communication to I2C and SPI slave devices

This debug probe firmware is compatible with the following debug host tools:

- *LinkServer Debug Host Tools*

The probe may be updated to use CMSIS-DAP firmware with the following steps:

1. Make sure the LPCScrypt utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the LPC-Link2 microcontroller into DFU boot mode by attaching the DFU jumper, then connecting to the USB debug port on the board. This jumper is connected to `P2_6` on the LPC4322 SOC.
3. Run the `program_CMSIS` script, found in the installed LPCScrypt `scripts` folder.

4. Remove the DFU jumper and power cycle the board.

> **Note**
>
> On some boards, the J-Link probe firmware will no longer power the board via the USB debug port. On these boards, an alternative method of powering the board must be used when this firmware is programmed.

LPC-Link2 J-Link Onboard Debug Probe This debug probe firmware provides a JLink compatible debug interface, as well as a USB-Serial adapter. It is compatible with the following debug host tools:

- *J-Link Debug Host Tools*

The probe may be updated to use the J-Link firmware with the following steps:

> **Note**
>
> Verify the firmware supports your board by visiting Firmware for LPCXpresso

1. Make sure the LPCScrypt utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the LPC-Link2 microcontroller into DFU boot mode by attaching the DFU jumper, then connecting to the USB debug port on the board. This jumper is connected to `P2_6` on the LPC4322 SOC.
3. Run the `program_JLINK` script, found in the installed LPCScrypt `scripts` folder.
4. Remove the DFU jumper and power cycle the board.

LPC-Link2 DAPLink Onboard Debug Probe The LPC-Link2 DAPLink firmware is the default firmware shipped on LPC-Link2 based boards, but is not the recommended firmware. Users should update to the *LPC-LINK2 CMSIS DAP Onboard Debug Probe* firmware following the instructions provided above. For details on programming the DAPLink firmware, see NXP AN13206.

OpenSDA Onboard Debug Probe

The OpenSDA onboard debug probe is based on the NXP MK20 SOC. It features drag and drop programming supports, and supports the following debug firmwares:

- *OpenSDA DAPLink Onboard Debug Probe* (default firmware)
- *OpenSDA J-Link Onboard Debug Probe*

OpenSDA DAPLink Onboard Debug Probe This debug probe firmware is compatible with the following debug host tools:

- *pyOCD Debug Host Tools*
- *OpenOCD Debug Host Tools*
- *LinkServer Debug Host Tools*

This probe is realized by programming the OpenSDA microcontroller with DAPLink OpenSDA firmware. NXP provides OpenSDA DAPLink Board-Specific Firmwares.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you power on the board. Note that "bootloader mode" in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.
2. After you power on the board, release the reset button. A USB mass storage device called **BOOTLOADER** or **MAINTENANCE** will enumerate. If the enumerated device is named **BOOTLOADER**, please first update the bootloader to the latest revision by following the instructions for a DAPLink Bootloader Update.
3. Copy the OpenSDA firmware binary to the USB mass storage device.
4. Power cycle the board, this time without holding the reset button. You should see three USB devices enumerate: a CDC device (serial port), a HID device (debug port), and a mass storage device (drag-and-drop flash programming).

OpenSDA J-Link Onboard Debug Probe This debug probe is compatible with the following debug host tools:

- *J-Link Debug Host Tools*

This probe is realized by programming the OpenSDA microcontroller with J-Link OpenSDA firmware. Segger provides OpenSDA J-Link Generic Firmwares and OpenSDA J-Link Board-Specific Firmwares, where the latter is generally recommended when available. Board-specific firmwares are required for i.MX RT boards to support their external flash memories, whereas generic firmwares are compatible with all Kinetis boards.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you plug a USB into the board's USB debug port. Note that "bootloader mode" in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.
2. After you power on the board, release the reset button. A USB mass storage device called **BOOTLOADER** or **MAINTENANCE** will enumerate. If the enumerated device is named **BOOTLOADER**, please first update the bootloader to the latest revision by following the instructions for a DAPLink Bootloader Update.
3. Copy the OpenSDA firmware binary to the USB mass storage device.
4. Power cycle the board, this time without holding the reset button. You should see two USB devices enumerate: a CDC device (serial port) and a vendor-specific device (debug port).

J-Link External Debug Probe

Segger J-Link is a family of external debug probes, including J-Link EDU, J-Link PLUS, J-Link ULTRA+, and J-Link PRO, that support a large number of devices from different hardware architectures and vendors.

This debug probe is compatible with the following debug host tools:

- *J-Link Debug Host Tools*
- *OpenOCD Debug Host Tools*

Install the debug host tools before you program the firmware.

ST-LINK/V2-1 Onboard Debug Probe

ST-LINK/V2-1 is a serial and debug adapter built into all Nucleo and Discovery boards. It provides a bridge between your computer (or other USB host) and the embedded target processor, which can be used for debugging, flash programming, and serial communication, all over a simple USB cable.

It is compatible with the following host debug tools:

- *OpenOCD Debug Host Tools*
- *J-Link Debug Host Tools*

For some STM32 based boards, it is also compatible with:

- *pyOCD Debug Host Tools*

While it works out of the box with OpenOCD, it requires some flashing to work with J-Link. To do this, SEGGER offers a firmware upgrading the ST-LINK/V2-1 on board on the Nucleo and Discovery boards. This firmware makes the ST-LINK/V2-1 compatible with J-LinkOB, allowing users to take advantage of most J-Link features like the ultra fast flash download and debugging speed or the free-to-use GDBServer.

More information about upgrading ST-LINK/V2-1 to JLink or restore ST-Link/V2-1 firmware please visit: Segger over ST-Link

Flash and debug with ST-Link Using OpenOCD

OpenOCD is available by default on ST-Link and configured as the default flash and debug tool. Flash and debug can be done as follows:

```
# From the root of the zephyr repository
west build -b None samples/hello_world
west flash
```

```
# From the root of the zephyr repository
west build -b None samples/hello_world
west debug
```

Using Segger J-Link

Once STLink is flashed with SEGGER FW and J-Link GDB server is installed on your host computer, you can flash and debug as follows:

Use CMake with `-DBOARD_FLASH_RUNNER=jlink` to change the default OpenOCD runner to J-Link. Alternatively, you might add the following line to your application `CMakeList.txt` file.

```
set(BOARD_FLASH_RUNNER jlink)
```

If you use West (Zephyr's meta-tool) you can modify the default runner using the `--runner` (or `-r`) option.

```
west flash --runner jlink
```

To attach a debugger to your board and open up a debug console with `jlink`.

```
west debug --runner jlink
```

For more information about West and available options, see *West (Zephyr's meta-tool)*.

If you configured your Zephyr application to use Segger RTT console instead, open telnet:

```
$ telnet localhost 19021
Trying ::1...
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
SEGGER J-Link V6.30f - Real time terminal output
J-Link STLink V21 compiled Jun 26 2017 10:35:16 V1.0, SN=773895351
Process: JLinkGDBServerCLExe
Zephyr Shell, Zephyr version: 1.12.99
Type 'help' for a list of available commands
shell>
```

If you get no RTT output you might need to disable other consoles which conflict with the RTT one if they are enabled by default in the particular sample or application you are running, such as disable UART_CONSOLE in menuconfig

Updating or restoring ST-Link firmware ST-Link firmware can be updated using STM32CubeProgrammer Tool. It is usually useful when facing flashing issues, for instance when using twister's device-testing option.

Once installed, you can update attached board ST-Link firmware with the following command

```
s java -jar ~/STMicroelectronics/STM32Cube/STM32CubeProgrammer/Drivers/
↪FirmwareUpgrade/STLinkUpgrade.jar -sn <board_uid>
```

Where board_uid can be obtained using twister's generate-hardware-map option. For more information about twister and available options, see *Test Runner (Twister)*.

NXP S32 Debug Probe

NXP S32 Debug Probe enables NXP S32 target system debugging via a standard debug port while connected to a developer's workstation via USB or remotely via Ethernet.

NXP S32 Debug Probe is designed to work in conjunction with NXP S32 Design Studio (S32DS) and NXP Automotive microcontrollers and processors. Install the debug host tools as in indicated in *NXP S32 Debug Probe Host Tools* before you program the firmware.

2.10 Modules (External projects)

Zephyr relies on the source code of several externally maintained projects in order to avoid reinventing the wheel and to reuse as much well-established, mature code as possible when it makes sense. In the context of Zephyr's build system those are called *modules*. These modules must be integrated with the Zephyr build system, as described in more detail in other sections on this page.

To be classified as a candidate for being included in the default list of modules, an external project is required to have its own life-cycle outside the Zephyr Project, that is, reside in its own repository, and have its own contribution and maintenance workflow and release process. Zephyr modules should not contain code that is written exclusively for Zephyr. Instead, such code should be contributed to the main zephyr tree.

Modules to be included in the default manifest of the Zephyr project need to provide functionality or features endorsed and approved by the project Technical Steering Committee and should comply with the *module licensing requirements* and *contribution guidelines*. They should also have a Zephyr developer that is committed to maintain the module codebase.

Zephyr depends on several categories of modules, including but not limited to:

- Debugger integration
- Silicon vendor Hardware Abstraction Layers (HALs)
- Cryptography libraries
- File Systems
- Inter-Process Communication (IPC) libraries

Additionally, in some cases modules (particularly vendor HALs) can contain references to optional *binary blobs*.

This page summarizes a list of policies and best practices which aim at better organizing the workflow in Zephyr modules.

2.10.1 Modules vs west projects

Zephyr modules, described in this page, are not the same as *west projects*. In fact, modules *do not require west* at all. However, when using modules *with west*, then the build system uses west in order to find modules.

In summary:

Modules are repositories that contain a `zephyr/module.yml` file, so that the Zephyr build system can pull in the source code from the repository. *West projects* are entries in the *projects:* section in the `west.yml` manifest file. West projects are often also modules, but not always. There are west projects that are not included in the final firmware image (eg. tools) and thus do not need to be modules. Modules are found by the Zephyr build system either via *west itself*, or via the *ZEPHYR_MODULES CMake variable*.

The contents of this page only apply to modules, and not to west projects in general (unless they are a module themselves).

2.10.2 Module Repositories

- All modules included in the default manifest shall be hosted in repositories under the zephyrproject-rtos GitHub organization.
- The module repository codebase shall include a *module.yml* file in a `zephyr/` folder at the root of the repository.
- Module repository names should follow the convention of using lowercase letters and dashes instead of underscores. This rule will apply to all new module repositories, except for repositories that are directly tracking external projects (hosted in Git repositories); such modules may be named as their external project counterparts.

> **Note**
>
> Existing module repositories that do not conform to the above convention do not need to be renamed to comply with the above convention.

- Module repositories names should be explicitly set in the `zephyr/module.yml` file.
- Modules should use “zephyr” as the default name for the repository main branch. Branches for specific purposes, for example, a module branch for an LTS Zephyr version, shall have names starting with the ‘zephyr_’ prefix.
- If the module has an external (upstream) project repository, the module repository should preserve the upstream repository folder structure.

> **Note**
>
> It is not required in module repositories to maintain a 'master' branch mirroring the master branch of the external repository. It is not recommended as this may generate confusion around the module's main branch, which should be 'zephyr'.

- Modules should expose all provided header files with an include pathname beginning with the module-name. (E.g., mcuboot should expose its `bootutil/bootutil.h` as "mcuboot/bootutil/bootutil.h".)

Synchronizing with upstream

It is preferred to synchronize a module repository with the latest stable release of the corresponding external project. It is permitted, however, to update a Zephyr module repository with the latest development branch tip, if this is required to get important updates in the module codebase. When synchronizing a module with upstream it is mandatory to document the rationale for performing the particular update.

Requirements for allowed practices Changes to the main branch of a module repository, including synchronization with upstream code base, may only be applied via pull requests. These pull requests shall be *verifiable* by Zephyr CI and *mergeable* (e.g. with the *Rebase and merge*, or *Create a merge commit* option using Github UI). This ensures that the incoming changes are always **reviewable**, and the *downstream* module repository history is incremental (that is, existing commits, tags, etc. are always preserved). This policy also allows to run Zephyr CI, git lint, identity, and license checks directly on the set of changes that are to be brought into the module repository.

> **Note**
>
> Force-pushing to a module's main branch is not allowed.

Allowed practices The following practices conform to the above requirements and should be followed in all modules repositories. It is up to the module code owner to select the preferred synchronization practice, however, it is required that the selected practice is consistently followed in the respective module repository.

Updating modules with a diff from upstream: Upstream changes brought as a single *snapshot* commit (manual diff) in a pull request against the module's main branch, which may be merged using the *Rebase & merge* operation. This approach is simple and should be applicable to all modules with the downside of suppressing the upstream history in the module repository.

> **Note**
>
> The above practice is the only allowed practice in modules where the external project is not hosted in an upstream Git repository.

The commit message is expected to identify the upstream project URL, the version to which the module is updated (upstream version, tag, commit SHA, if applicable, etc.), and the reason for the doing the update.

Updating modules by merging the upstream branch: Upstream changes brought in by performing a Git merge of the intended upstream branch (e.g. main branch, latest release branch, etc.) submitting the result in pull request against the module main branch, and merging the pull

request using the *Create a merge commit* operation. This approach is applicable to modules with an upstream project Git repository. The main advantages of this approach is that the upstream repository history (that is, the original commit SHAs) is preserved in the module repository. The downside of this approach is that two additional merge commits are generated in the downstream main branch.

2.10.3 Contributing to Zephyr modules

Individual Roles & Responsibilities

To facilitate management of Zephyr module repositories, the following individual roles are defined.

Administrator: Each Zephyr module shall have an administrator who is responsible for managing access to the module repository, for example, for adding individuals as Collaborators in the repository at the request of the module owner. Module administrators are members of the Administrators team, that is a group of project members with admin rights to module GitHub repositories.

Module owner: Each module shall have a module code owner. Module owners will have the overall responsibility of the contents of a Zephyr module repository. In particular, a module owner will:

- coordinate code reviewing in the module repository
- be the default assignee in pull-requests against the repository's main branch
- request additional collaborators to be added to the repository, as they see fit
- regularly synchronize the module repository with its upstream counterpart following the policies described in *Synchronizing with upstream*
- be aware of security vulnerability issues in the external project and update the module repository to include security fixes, as soon as the fixes are available in the upstream code base
- list any known security vulnerability issues, present in the module codebase, in Zephyr release notes.

> **Note**
>
> Module owners are not required to be Zephyr *Maintainers*.

Merger: The Zephyr Release Engineering team has the right and the responsibility to merge approved pull requests in the main branch of a module repository.

Maintaining the module codebase

Updates in the zephyr main tree, for example, in public Zephyr APIs, may require patching a module's codebase. The responsibility for keeping the module codebase up to date is shared between the **contributor** of such updates in Zephyr and the module **owner**. In particular:

- the contributor of the original changes in Zephyr is required to submit the corresponding changes that are required in module repositories, to ensure that Zephyr CI on the pull request with the original changes, as well as the module integration testing are successful.
- the module owner has the overall responsibility for synchronizing and testing the module codebase with the zephyr main tree. This includes occasional advanced testing of the module's codebase in addition to the testing performed by Zephyr's CI. The module owner is

required to fix issues in the module's codebase that have not been caught by Zephyr pull request CI runs.

Contributing changes to modules

Submitting and merging changes directly to a module's codebase, that is, before they have been merged in the corresponding external project repository, should be limited to:

- changes required due to updates in the zephyr main tree
- urgent changes that should not wait to be merged in the external project first, such as fixes to security vulnerabilities.

Non-trivial changes to a module's codebase, including changes in the module design or functionality should be discouraged, if the module has an upstream project repository. In that case, such changes shall be submitted to the upstream project, directly.

Submitting changes to modules describes in detail the process of contributing changes to module repositories.

Contribution guidelines Contributing to Zephyr modules shall follow the generic project *Contribution guidelines*.

Pull Requests: may be merged with minimum of 2 approvals, including an approval by the PR assignee. In addition to this, pull requests in module repositories may only be merged if the introduced changes are verified with Zephyr CI tools, as described in more detail in other sections on this page.

The merging of pull requests in the main branch of a module repository must be coupled with the corresponding manifest file update in the zephyr main tree.

Issue Reporting: GitHub issues are intentionally disabled in module repositories, in favor of a centralized policy for issue reporting. Tickets concerning, for example, bugs or enhancements in modules shall be opened in the main zephyr repository. Issues should be appropriately labeled using GitHub labels corresponding to each module, where applicable.

> **Note**
>
> It is allowed to file bug reports for zephyr modules to track the corresponding upstream project bugs in Zephyr. These bug reports shall not affect the *Release Quality Criteria*.

2.10.4 Licensing requirements and policies

All source files in a module's codebase shall include a license header, unless the module repository has **main license file** that covers source files that do not include license headers.

Main license files shall be added in the module's codebase by Zephyr developers, only if they exist as part of the external project, and they contain a permissive OSI-compliant license. Main license files should preferably contain the full license text instead of including an SPDX license identifier. If multiple main license files are present it shall be made clear which license applies to each source file in a module's codebase.

Individual license headers in module source files supersede the main license.

Any new content to be added in a module repository will require to have license coverage.

> **Note**
>
> Zephyr recommends conveying module licensing via individual license headers and main license files. This not a hard requirement; should an external project have its own practice of conveying how licensing applies in the module's codebase (for example, by having a single or multiple main license files), this practice may be accepted by and be referred to in the Zephyr module, as long as licensing requirements, for example OSI compliance, are satisfied.

License policies

When creating a module repository a developer shall:

- import the main license files, if they exist in the external project, and
- document (for example in the module README or .yml file) the default license that covers the module's codebase.

License checks License checks (via CI tools) shall be enabled on every pull request that adds new content in module repositories.

2.10.5 Documentation requirements

All Zephyr module repositories shall include an .rst file documenting:

- the scope and the purpose of the module
- how the module integrates with Zephyr
- the owner of the module repository
- synchronization information with the external project (commit, SHA, version etc.)
- licensing information as described in *Licensing requirements and policies*.

The file shall be required for the inclusion of the module and the contained information should be kept up to date.

2.10.6 Testing requirements

All Zephyr modules should provide some level of **integration** testing, ensuring that the integration with Zephyr works correctly. Integration tests:

- may be in the form of a minimal set of samples and tests that reside in the zephyr main tree
- should verify basic usage of the module (configuration, functional APIs, etc.) that is integrated with Zephyr.
- shall be built and executed (for example in QEMU) as part of twister runs in pull requests that introduce changes in module repositories.

> **Note**
>
> New modules, that are candidates for being included in the Zephyr default manifest, shall provide some level of integration testing.

> **Note**
>
> Vendor HALs are implicitly tested via Zephyr tests built or executed on target platforms, so they do not need to provide integration tests.

The purpose of integration testing is not to provide functional verification of the module; this should be part of the testing framework of the external project.

Certain external projects provide test suites that reside in the upstream testing infrastructure but are written explicitly for Zephyr. These tests may (but are not required to) be part of the Zephyr test framework.

2.10.7 Deprecating and removing modules

Modules may be deprecated for reasons including, but not limited to:

- Lack of maintainership in the module
- Licensing changes in the external project
- Codebase becoming obsolete

The module information shall indicate whether a module is deprecated and the build system shall issue a warning when trying to build Zephyr using a deprecated module.

Deprecated modules may be removed from the Zephyr default manifest after 2 Zephyr releases.

> **Note**
>
> Repositories of removed modules shall remain accessible via their original URL, as they are required by older Zephyr versions.

2.10.8 Integrate modules in Zephyr build system

The build system variable **ZEPHYR_MODULES** is a CMake list of absolute paths to the directories containing Zephyr modules. These modules contain `CMakeLists.txt` and `Kconfig` files describing how to build and configure them, respectively. Module `CMakeLists.txt` files are added to the build using CMake's add_subdirectory() command, and the `Kconfig` files are included in the build's Kconfig menu tree.

If you have *west* installed, you don't need to worry about how this variable is defined unless you are adding a new module. The build system knows how to use west to set **ZEPHYR_MODULES**. You can add additional modules to this list by setting the **EXTRA_ZEPHYR_MODULES** CMake variable or by adding a **EXTRA_ZEPHYR_MODULES** line to `.zephyrrc` (See the section on *Environment Variables* for more details). This can be useful if you want to keep the list of modules found with west and also add your own.

> **Note**
>
> If the module `FOO` is provided by *west* but also given with `-DEXTRA_ZEPHYR_MODULES=/<path>/foo` then the module given by the command line variable **EXTRA_ZEPHYR_MODULES** will take precedence. This allows you to use a custom version of `FOO` when building and still use other Zephyr modules provided by *west*. This can for example be useful for special test purposes.

If you want to permanently add modules to the zephyr workspace and you are using zephyr as your manifest repository, you can also add a west manifest file into the submanifests directory. See submanifests/README.txt for more details.

See *Basics* for more on west workspaces.

Finally, you can also specify the list of modules yourself in various ways, or not use modules at all if your application doesn't need them.

2.10.9 Module yaml file description

A module can be described using a file named `zephyr/module.yml`. The format of `zephyr/module.yml` is described in the following:

Module name

Each Zephyr module is given a name by which it can be referred to in the build system.

The name should be specified in the `zephyr/module.yml` file. This will ensure the module name is not changeable through user-defined directory names or `west` manifest files:

```
name: <name>
```

In CMake the location of the Zephyr module can then be referred to using the CMake variable `ZEPHYR_<MODULE_NAME>_MODULE_DIR` and the variable `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` holds the location of the directory containing the module's `CMakeLists.txt` file.

> **Note**
>
> When used for CMake and Kconfig variables, all letters in module names are converted to uppercase and all non-alphanumeric characters are converted to underscores (_). As example, the module `foo-bar` must be referred to as `ZEPHYR_FOO_BAR_MODULE_DIR` in CMake and Kconfig.

Here is an example for the Zephyr module `foo`:

```
name: foo
```

> **Note**
>
> If the `name` field is not specified then the Zephyr module name will be set to the name of the module folder. As example, the Zephyr module located in `<workspace>/modules/bar` will use `bar` as its module name if nothing is specified in `zephyr/module.yml`.

Module integration files (in-module)

Inclusion of build files, `CMakeLists.txt` and `Kconfig`, can be described as:

```
build:
  cmake: <cmake-directory>
  kconfig: <directory>/Kconfig
```

The `cmake: <cmake-directory>` part specifies that `<cmake-directory>` contains the `CMakeLists.txt` to use. The `kconfig: <directory>/Kconfig` part specifies the Kconfig file to use. Neither is required: `cmake` defaults to `zephyr`, and `kconfig` defaults to `zephyr/Kconfig`.

Here is an example `module.yml` file referring to `CMakeLists.txt` and `Kconfig` files in the root directory of the module:

```
build:
  cmake: .
  kconfig: Kconfig
```

Sysbuild integration

Sysbuild is the Zephyr build system that allows for building multiple images as part of a single application, the sysbuild build process can be extended externally with modules as needed, for example to add custom build steps or add additional targets to a build. Inclusion of sysbuild-specific build files, `CMakeLists.txt` and `Kconfig`, can be described as:

```
build:
  sysbuild-cmake: <cmake-directory>
  sysbuild-kconfig: <directory>/Kconfig
```

The `sysbuild-cmake: <cmake-directory>` part specifies that `<cmake-directory>` contains the `CMakeLists.txt` to use. The `sysbuild-kconfig: <directory>/Kconfig` part specifies the Kconfig file to use.

Here is an example `module.yml` file referring to `CMakeLists.txt` and `Kconfig` files in the *sysbuild* directory of the module:

```
build:
  sysbuild-cmake: sysbuild
  sysbuild-kconfig: sysbuild/Kconfig
```

The module description file `zephyr/module.yml` can also be used to specify that the build files, `CMakeLists.txt` and `Kconfig`, are located in a *Module integration files (external)*.

Build files located in a `MODULE_EXT_ROOT` can be described as:

```
build:
  sysbuild-cmake-ext: True
  sysbuild-kconfig-ext: True
```

This allows control of the build inclusion to be described externally to the Zephyr module.

Vulnerability monitoring

The module description file `zephyr/module.yml` can be used to improve vulnerability monitoring.

If your module needs to track vulnerabilities using an external reference (e.g your module is forked from another repository), you can use the `security` section. It contains the field `external-references` that contains a list of references that needs to be monitored for your module. The supported formats are:

- CPE (Common Platform Enumeration)
- PURL (Package URL)

```
security:
  external-references:
    - <module-related-cpe>
    - <an-other-module-related-cpe>
    - <module-related-purl>
```

A real life example for *mbedTLS* module could look like this:

```
security:
  external-references:
    - cpe:2.3:a:arm:mbed_tls:3.5.2:*:*:*:*:*:*:*
    - pkg:github/Mbed-TLS/mbedtls@V3.5.2
```

Note

CPE field must follow the CPE 2.3 schema provided by NVD. PURL field must follow the PURL specification provided by Github.

Build system integration

When a module has a `module.yml` file, it will automatically be included into the Zephyr build system. The path to the module is then accessible through Kconfig and CMake variables.

Zephyr modules In both Kconfig and CMake, the variable `ZEPHYR_<MODULE_NAME>_MODULE_DIR` contains the absolute path to the module.

In CMake, `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` contains the absolute path to the directory containing the `CMakeLists.txt` file that is included into CMake build system. This variable's value is empty if the module.yml file does not specify a CMakeLists.txt.

To read these variables for a Zephyr module named `foo`:

- In CMake: use `${ZEPHYR_FOO_MODULE_DIR}` for the module's top level directory, and `${ZEPHYR_FOO_CMAKE_DIR}` for the directory containing its `CMakeLists.txt`
- In Kconfig: use `$(ZEPHYR_FOO_MODULE_DIR)` for the module's top level directory

Notice how a lowercase module name `foo` is capitalized to `FOO` in both CMake and Kconfig.

These variables can also be used to test whether a given module exists. For example, to verify that `foo` is the name of a Zephyr module:

```
if(ZEPHYR_FOO_MODULE_DIR)
  # Do something if FOO exists.
endif()
```

In Kconfig, the variable may be used to find additional files to include. For example, to include the file `some/Kconfig` in module `foo`:

```
source "$(ZEPHYR_FOO_MODULE_DIR)/some/Kconfig"
```

During CMake processing of each Zephyr module, the following variables are also available:

- the current module's name: `${ZEPHYR_CURRENT_MODULE_NAME}`
- the current module's top level directory: `${ZEPHYR_CURRENT_MODULE_DIR}`
- the current module's `CMakeLists.txt` directory: `${ZEPHYR_CURRENT_CMAKE_DIR}`

This removes the need for a Zephyr module to know its own name during CMake processing. The module can source additional CMake files using these `CURRENT` variables. For example:

```
include(${ZEPHYR_CURRENT_MODULE_DIR}/cmake/code.cmake)
```

It is possible to append values to a Zephyr CMake list variable from the module's first CMakeLists.txt file. To do so, append the value to the list and then set the list in the PARENT_SCOPE of the CMakeLists.txt file. For example, to append `bar` to the `FOO_LIST` variable in the Zephyr CMakeLists.txt scope:

```
list(APPEND FOO_LIST bar)
set(FOO_LIST ${FOO_LIST} PARENT_SCOPE)
```

An example of a Zephyr list where this is useful is when adding additional directories to the SYSCALL_INCLUDE_DIRS list.

Sysbuild modules In both Kconfig and CMake, the variable SYSBUILD_CURRENT_MODULE_DIR contains the absolute path to the sysbuild module. In CMake, SYSBUILD_CURRENT_CMAKE_DIR contains the absolute path to the directory containing the CMakeLists.txt file that is included into CMake build system. This variable's value is empty if the module.yml file does not specify a CMakeLists.txt.

To read these variables for a sysbuild module:

- In CMake: use ${SYSBUILD_CURRENT_MODULE_DIR} for the module's top level directory, and ${SYSBUILD_CURRENT_CMAKE_DIR} for the directory containing its CMakeLists.txt
- In Kconfig: use $(SYSBUILD_CURRENT_MODULE_DIR) for the module's top level directory

In Kconfig, the variable may be used to find additional files to include. For example, to include the file some/Kconfig:

```
source "$(SYSBUILD_CURRENT_MODULE_DIR)/some/Kconfig"
```

The module can source additional CMake files using these variables. For example:

```
include(${SYSBUILD_CURRENT_MODULE_DIR}/cmake/code.cmake)
```

It is possible to append values to a Zephyr CMake list variable from the module's first CMakeLists.txt file. To do so, append the value to the list and then set the list in the PARENT_SCOPE of the CMakeLists.txt file. For example, to append bar to the FOO_LIST variable in the Zephyr CMakeLists.txt scope:

```
list(APPEND FOO_LIST bar)
set(FOO_LIST ${FOO_LIST} PARENT_SCOPE)
```

Sysbuild modules hooks Sysbuild provides an infrastructure which allows a sysbuild module to define a function which will be invoked by sysbuild at a pre-defined point in the CMake flow.

Functions invoked by sysbuild:

- <module-name>_pre_cmake(IMAGES <images>): This function is called for each sysbuild module before CMake configure is invoked for all images.
- <module-name>_post_cmake(IMAGES <images>): This function is called for each sysbuild module after CMake configure has completed for all images.
- <module-name>_pre_domains(IMAGES <images>): This function is called for each sysbuild module before domains yaml is created by sysbuild.
- <module-name>_post_domains(IMAGES <images>): This function is called for each sysbuild module after domains yaml has been created by sysbuild.

arguments passed from sysbuild to the function defined by a module:

- <images> is the list of Zephyr images that will be created by the build system.

If a module foo want to provide a post CMake configure function, then the module's sysbuild CMakeLists.txt file must define function foo_post_cmake().

To facilitate naming of functions, the module name is provided by sysbuild CMake through the SYSBUILD_CURRENT_MODULE_NAME CMake variable when loading the module's sysbuild CMakeLists.txt file.

Example of how the foo sysbuild module can define foo_post_cmake():

```
function(${SYSBUILD_CURRENT_MODULE_NAME}_post_cmake)
  cmake_parse_arguments(POST_CMAKE "" "" "IMAGES" ${ARGN})

  message("Invoking ${CMAKE_CURRENT_FUNCTION}. Images: ${POST_CMAKE_IMAGES}")
endfunction()
```

Zephyr module dependencies

A Zephyr module may be dependent on other Zephyr modules to be present in order to function correctly. Or it might be that a given Zephyr module must be processed after another Zephyr module, due to dependencies of certain CMake targets.

Such a dependency can be described using the depends field.

```
build:
  depends:
    - <module>
```

Here is an example for the Zephyr module foo that is dependent on the Zephyr module bar to be present in the build system:

```
name: foo
build:
  depends:
    - bar
```

This example will ensure that bar is present when foo is included into the build system, and it will also ensure that bar is processed before foo.

Module integration files (external)

Module integration files can be located externally to the Zephyr module itself. The MODULE_EXT_ROOT variable holds a list of roots containing integration files located externally to Zephyr modules.

Module integration files in Zephyr The Zephyr repository contain CMakeLists.txt and Kconfig build files for certain known Zephyr modules.

Those files are located under

```
<ZEPHYR_BASE>
└── modules
    └── <module_name>
        ├── CMakeLists.txt
        └── Kconfig
```

Module integration files in a custom location You can create a similar MODULE_EXT_ROOT for additional modules, and make those modules known to Zephyr build system.

Create a MODULE_EXT_ROOT with the following structure

```
<MODULE_EXT_ROOT>
└── modules
    ├── modules.cmake
    └── <module_name>
```

(continues on next page)

(continued from previous page)

```
        ├── CMakeLists.txt
        └── Kconfig
```

and then build your application by specifying `-DMODULE_EXT_ROOT` parameter to the CMake build system. The `MODULE_EXT_ROOT` accepts a CMake list of roots as argument.

A Zephyr module can automatically be added to the `MODULE_EXT_ROOT` list using the module description file `zephyr/module.yml`, see *Build settings*.

Note

`ZEPHYR_BASE` is always added as a `MODULE_EXT_ROOT` with the lowest priority. This allows you to overrule any integration files under `<ZEPHYR_BASE>/modules/<module_name>` with your own implementation your own `MODULE_EXT_ROOT`.

The `modules.cmake` file must contain the logic that specifies the integration files for Zephyr modules via specifically named CMake variables.

To include a module's CMake file, set the variable `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` to the path containing the CMake file.

To include a module's Kconfig file, set the variable `ZEPHYR_<MODULE_NAME>_KCONFIG` to the path to the Kconfig file.

The following is an example on how to add support the `FOO` module.

Create the following structure

```
<MODULE_EXT_ROOT>
└── modules
    ├── modules.cmake
    └── foo
        ├── CMakeLists.txt
        └── Kconfig
```

and inside the `modules.cmake` file, add the following content

```
set(ZEPHYR_FOO_CMAKE_DIR ${CMAKE_CURRENT_LIST_DIR}/foo)
set(ZEPHYR_FOO_KCONFIG   ${CMAKE_CURRENT_LIST_DIR}/foo/Kconfig)
```

Module integration files (zephyr/module.yml) The module description file `zephyr/module.yml` can be used to specify that the build files, `CMakeLists.txt` and `Kconfig`, are located in a *Module integration files (external)*.

Build files located in a `MODULE_EXT_ROOT` can be described as:

```
build:
  cmake-ext: True
  kconfig-ext: True
```

This allows control of the build inclusion to be described externally to the Zephyr module.

The Zephyr repository itself is always added as a Zephyr module ext root.

Build settings

It is possible to specify additional build settings that must be used when including the module into the build system.

All `root` settings are relative to the root of the module.

Build settings supported in the `module.yml` file are:

- `board_root`: Contains additional boards that are available to the build system. Additional boards must be located in a `<board_root>/boards` folder.
- `dts_root`: Contains additional dts files related to the architecture/soc families. Additional dts files must be located in a `<dts_root>/dts` folder.
- `snippet_root`: Contains additional snippets that are available for use. These snippets must be defined in `snippet.yml` files underneath the `<snippet_root>/snippets` folder. For example, if you have `snippet_root: foo`, then you should place your module's `snippet.yml` files in `<your-module>/foo/snippets` or any nested subdirectory.
- `soc_root`: Contains additional SoCs that are available to the build system. Additional SoCs must be located in a `<soc_root>/soc` folder.
- `arch_root`: Contains additional architectures that are available to the build system. Additional architectures must be located in a `<arch_root>/arch` folder.
- `module_ext_root`: Contains `CMakeLists.txt` and `Kconfig` files for Zephyr modules, see also *Module integration files (external)*.
- `sca_root`: Contains additional *SCA* tool implementations available to the build system. Each tool must be located in `<sca_root>/sca/<tool>` folder. The folder must contain a `sca.cmake`.

Example of a `module.yaml` file containing additional roots, and the corresponding file system layout.

```
build:
  settings:
    board_root: .
    dts_root: .
    soc_root: .
    arch_root: .
    module_ext_root: .
```

requires the following folder structure:

```
<zephyr-module-root>
├── arch
├── boards
├── dts
├── modules
└── soc
```

Twister (Test Runner)

To execute both tests and samples available in modules, the Zephyr test runner (twister) should be pointed to the directories containing those samples and tests. This can be done by specifying the path to both samples and tests in the `zephyr/module.yml` file. Additionally, if a module defines out of tree boards, the module file can point twister to the path where those files are maintained in the module. For example:

```
build:
  cmake: .
samples:
  - samples
tests:
  - tests
```

(continues on next page)

(continued from previous page)

```
boards:
  - boards
```

Binary Blobs

Zephyr supports fetching and using *binary blobs*, and their metadata is contained entirely in `zephyr/module.yml`. This is because a binary blob must always be associated with a Zephyr module, and thus the blob metadata belongs in the module's description itself.

Binary blobs are fetched using *west blobs*. If `west` is *not used*, they must be downloaded and verified manually.

The `blobs` section in `zephyr/module.yml` consists of a sequence of maps, each of which has the following entries:

- `path`: The path to the binary blob, relative to the `zephyr/blobs/` folder in the module repository
- `sha256`: SHA-256 checksum of the binary blob file
- `type`: The *type of binary blob*. Currently limited to `img` or `lib`
- `version`: A version string
- `license-path`: Path to the license file for this blob, relative to the root of the module repository
- `url`: URL that identifies the location the blob will be fetched from, as well as the fetching scheme to use
- `description`: Human-readable description of the binary blob
- `doc-url`: A URL pointing to the location of the official documentation for this blob

Module Inclusion

Using West If west is installed and `ZEPHYR_MODULES` is not already set, the build system finds all the modules in your *west installation* and uses those. It does this by running *west list* to get the paths of all the projects in the installation, then filters the results to just those projects which have the necessary module metadata files.

Each project in the `west list` output is tested like this:

- If the project contains a file named `zephyr/module.yml`, then the content of that file will be used to determine which files should be added to the build, as described in the previous section.
- Otherwise (i.e. if the project has no `zephyr/module.yml`), the build system looks for `zephyr/CMakeLists.txt` and `zephyr/Kconfig` files in the project. If both are present, the project is considered a module, and those files will be added to the build.
- If neither of those checks succeed, the project is not considered a module, and is not added to `ZEPHYR_MODULES`.

Without West If you don't have west installed or don't want the build system to use it to find Zephyr modules, you can set `ZEPHYR_MODULES` yourself using one of the following options. Each of the directories in the list must contain either a `zephyr/module.yml` file or the files `zephyr/CMakeLists.txt` and `Kconfig`, as described in the previous section.

1. At the CMake command line, like this:

```
cmake -DZEPHYR_MODULES=<path-to-module1>[;<path-to-module2>[...]] ...
```

2. At the top of your application's top level `CMakeLists.txt`, like this:

```
set(ZEPHYR_MODULES <path-to-module1> <path-to-module2> [...])
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

   If you choose this option, make sure to set the variable **before** calling `find_package(Zephyr ...)`, as shown above.

3. In a separate CMake script which is pre-loaded to populate the CMake cache, like this:

```
# Put this in a file with a name like "zephyr-modules.cmake"
set(ZEPHYR_MODULES <path-to-module1> <path-to-module2>
  CACHE STRING "pre-cached modules")
```

   You can tell the build system to use this file by adding `-C zephyr-modules.cmake` to your CMake command line.

Not using modules If you don't have west installed and don't specify `ZEPHYR_MODULES` yourself, then no additional modules are added to the build. You will still be able to build any applications that don't require code or Kconfig options defined in an external repository.

2.10.10 Submitting changes to modules

When submitting new or making changes to existing modules the main repository Zephyr needs a reference to the changes to be able to verify the changes. In the main tree this is done using revisions. For code that is already merged and part of the tree we use the commit hash, a tag, or a branch name. For pull requests however, we require specifying the pull request number in the revision field to allow building the zephyr main tree with the changes submitted to the module.

To avoid merging changes to master with pull request information, the pull request should be marked as `DNM` (Do Not Merge) or preferably a draft pull request to make sure it is not merged by mistake and to allow for the module to be merged first and be assigned a permanent commit hash. Drafts reduce noise by not automatically notifying anyone until marked as "Ready for review". Once the module is merged, the revision will need to be changed either by the submitter or by the maintainer to the commit hash of the module which reflects the changes.

Note that multiple and dependent changes to different modules can be submitted using exactly the same process. In this case you will change multiple entries of all modules that have a pull request against them.

Process for submitting a new module

Please follow the process in *Submission and review process* and obtain the TSC approval to integrate the external source code as a module

If the request is approved, a new repository will created by the project team and initialized with basic information that would allow submitting code to the module project following the project contribution guidelines.

If a module is maintained as a fork of another project on Github, the Zephyr module related files and changes in relation to upstream need to be maintained in a special branch named `zephyr`.

Maintainers from the Zephyr project will create the repository and initialize it. You will be added as a collaborator in the new repository. Submit the module content (code) to the new repository following the guidelines described *here*, and then add a new entry to the west.yml with the following information:

```
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add *my_module* to the manifest:

```
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the *my_module* repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

Process for submitting changes to existing modules

1. Submit the changes using a pull request to an existing repository following the *contribution guidelines* and *expectations*.
2. Submit a pull request changing the entry referencing the module into the west.yml of the main Zephyr tree with the following information:

```
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add *my_module* to the manifest:

```
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the *my_module* repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

2.11 West (Zephyr's meta-tool)

The Zephyr project includes a swiss-army knife command line tool named `west`[1]. West is developed in its own repository.

West's built-in commands provide a multiple repository management system with features inspired by Google's Repo tool and Git submodules. West is also "pluggable": you can write your own west extension commands which add additional features to west. Zephyr uses this to provide conveniences for building applications, flashing and debugging them, and more.

Like `git` and `docker`, the top-level `west` command takes some common options, a sub-command to run, and then options and arguments for that sub-command:

```
west [common-opts] <command> [opts] <args>
```

Since west v0.8, you can also run west like this:

```
python3 -m west [common-opts] <command> [opts] <args>
```

You can run `west --help` (or `west -h` for short) to get top-level help for available west commands, and `west <command> -h` for detailed help on each command.

[1] Zephyr is an English name for the Latin Zephyrus, the ancient Greek god of the west wind.

2.11.1 Installing west

West is written in Python 3 and distributed through PyPI. Use `pip3` to install or upgrade west:

On Linux:

```
pip3 install --user -U west
```

On Windows and macOS:

```
pip3 install -U west
```

Note

See *Python and pip* for additional clarification on using the `--user` switch.

Afterwards, you can run `pip3 show -f west` for information on where the west binary and related files were installed.

Once west is installed, you can use it to *clone the Zephyr repositories*.

Structure

West's code is distributed via PyPI in a Python package named `west`. This distribution includes a launcher executable, which is also named `west` (or `west.exe` on Windows).

When west is installed, the launcher is placed by `pip3` somewhere in the user's filesystem (exactly where depends on the operating system, but should be on the `PATH` *environment variable*). This launcher is the command-line entry point to running both built-in commands like `west init`, `west update`, along with any extensions discovered in the workspace.

In addition to its command-line interface, you can also use west's Python APIs directly. See west-apis for details.

Enabling shell completion

West currently supports shell completion in the following shells:

- bash
- zsh
- fish

In order to enable shell completion, you will need to obtain the corresponding completion script and have it sourced. Using the completion scripts:

bash

One-time setup:

```
source <(west completion bash)
```

Permanent setup:

```
west completion bash > ~/west-completion.bash; echo "source ~/west-completion.bash" >> ~/.
↪bashrc
```

zsh

One-time setup:

```
source <(west completion zsh)
```

Permanent setup:

```
west completion zsh > "${fpath[1]}/_west"
```

fish

One-time setup:

```
west completion fish | source
```

Permanent setup:

```
west completion fish > $HOME/.config/fish/completions/west.fish
```

2.11.2 West Release Notes

v1.2.0

Major changes:

- New `west grep` command for running a "grep tool" in your west workspace's repositories. Currently, `git grep`, ripgrep, and standard `grep` are supported grep tools.

  To run this command to get `git grep foo` results from all cloned, active repositories, run:

  ```
  west grep foo
  ```

  Here are some other examples for running different grep commands with `west grep`:

`git grep --untracked`	`west grep --untracked foo`
`ripgrep`	`west grep --tool ripgrep foo`
`grep --recursive`	`west grep --tool grep foo`

  To switch the default grep tool in your workspace, run the appropriate command in this table:

`ripgrep`	`west config grep.tool ripgrep`
`grep`	`west config grep.tool grep`

  For more details, run `west help grep`.

Other changes:

- The manifest file format now supports a `description` field in each `projects:` element. See *Projects* for examples.
- `west list --format` now accepts `{description}` in the format string, which prints the project's `description:` value.
- `west compare` now always prints information about *The manifest-rev branch*.

Bug fixes:

- `west init` aborts if the destination directory already exists.

API changes:

- `west.commands.WestCommand` methods `check_call()` and `check_output()` now take any kwargs that can be passed on to the underlying subprocess function.

- `west.commands.WestCommand.run_subprocess()`: new wrapper around `subprocess.run()`. This could not be named `run()` because `WestCommand` already had a method by this name.
- `west.commands.WestCommand` methods `dbg()`, `inf()`, `wrn()`, and `err()` now all take an `end` kwarg, which is passed on to the call to `print()`.
- `west.manifest.Project` now has a `description` attribute, which contains the parsed value of the `description:` field in the manifest data.

v1.1.0

Major changes:

- `west compare`: new command that compares the state of the workspace against the manifest.
- Support for a new `manifest.project-filter` configuration option. See *Built-in Configuration Options* for details. The `west manifest --freeze` and `west manifest --resolve` commands currently cannot be used when this option is set. This restriction can be removed in a later release.
- Project names which contain comma (`,`) or whitespace now generate warnings. These warnings are errors if the new `manifest.project-filter` configuration option is set. The warnings may be promoted to errors in a future major version of west.

Other changes:

- `west forall` now takese a `--group` argument that can be used to restrict the command to only run in one or more groups. Run `west help forall` for details.
- All west commands will now output log messages from west API modules at warning level or higher. In addition, the `--verbose` argument to west can be used once to include informational messages, or twice to include debug messages, from all commands.

Bug fixes:

- Various improvements to error messages, debug logging, and error handling.

API changes:

- `west.manifest.Manifest.is_active()` now respects the `manifest.project-filter` configuration option's value.

v1.0.1

Major changes:

- Manifest schema version "1.0" is now available for use in this release. This is identical to the "0.13" schema version in terms of features, but can be used by applications that do not wish to use a "0.x" manifest "version:" field. See *Version* for details on this feature.

Bug fixes:

- West no longer exits with a successful error code when sent an interrupt signal. Instead, it exits with a platform-specific error code and signals to the calling environment that the process was interrupted.

v1.0.0

Major changes in this release:

- The west-apis are now declared stable. Any breaking changes will be communicated by a major version bump from v1.x.y to v2.x.y.

- West v1.0 no longer works with the Zephyr v1.14 LTS releases. This LTS has long been obsoleted by Zephyr v2.7 LTS. If you need to use Zephyr v1.14, you must use west v0.14 or earlier.
- Like the rest of Zephyr, west now requires Python v3.8 or later
- West commands no longer accept abbreviated command line arguments. For example, you must now specify `west update --keep-descendants` instead of using an abbreviation like `west update --keep-d`. This is part of a change applied to all of Zephyr's Python scripts' command-line interfaces. The abbreviations were causing problems in practice when commands were updated to add new options with similar names but different behavior to existing ones.

Other changes:

- All built-in west functions have stopped using `west.log`
- `west update`: new `--submodule-init-config` option. See commit 9ba92b05 for details.

Bug fixes:

- West extension commands that failed to load properly sometimes dumped stack. This has been fixed and west now prints a sensible error message in this case.
- `west config` now fails on malformed configuration option arguments which lack a `.` in the option name

API changes:

- The west package now contains the metadata files necessary for some static analyzers (such as mypy) to auto-detect its type annotations. See commit d9f00e24 for details.
- the deprecated `west.build` module used for Zephyr v1.14 LTS compatibility was removed
- the deprecated `west.cmake` module used for Zephyr v1.14 LTS compatibility was removed
- the `west.log` module is now deprecated. This module uses global state, which can make it awkward to use it as an API which multiple different python modules may rely on.
- The west-apis-commands module got some new APIs which lay groundwork for a future change to add a global verbosity control to a command's output, and work to remove global state from the `west` package's API:
  - New `west.commands.WestCommand.__init__()` keyword argument: `verbosity`
  - New `west.commands.WestCommand` property: `color_ui`
  - New `west.commands.WestCommand` methods, which should be used to print output from extension commands instead of writing directly to sys.stdout or sys.stderr: `inf()`, `wrn()`, `err()`, `die()`, `banner()`, `small_banner()`
  - New `west.commands.VERBOSITY` enum

v0.14.0

Bug fixes:

- West commands that were run with a bad local configuration file dumped stack in a confusing way. This has been fixed and west now prints a sensible error message in this case.
- A bug in the way west looks for the zephyr repository was fixed. The bug itself usually appeared when running an extension command like `west build` in a new workspace for the first time; this used to fail (just for the first time, not on subsequent command invocations) unless you ran the command in the workspace's top level directory.
- West now prints sensible error messages when the user lacks permission to open the manifest file instead of dumping stack traces.

API changes:

- The `west.manifest.MalformedConfig` exception type has been moved to the `west.configuration` module
- The `west.manifest.MalformedConfig` exception type has been moved to the west.configuration module
- The `west.configuration.Configuration` class now raises `MalformedConfig` instead of `RuntimeError` in some cases

v0.13.1

Bug fix:

- When calling west.manifest.Manifest.from_file() when outside of a workspace, west again falls back on the ZEPHYR_BASE environment variable to locate the workspace.

v0.13.0

New features:

- You can now associate arbitrary user data with the manifest repository itself in the `manifest: self: userdata:` value, like so:

```
manifest:
  self:
    userdata: <any YAML value can go here>
```

Bug fixes:

- The path to the manifest repository reported by west could be incorrect in certain circumstances detailed in [issue #572](https://github.com/zephyrproject-rtos/west/issues/572). This has been fixed as part of a larger overhaul of path handling support in the `west.manifest` API module.
- The `west.Manifest.ManifestProject.__repr__` return value was fixed

API changes:

- `west.configuration.Configuration`: new object-oriented interface to the current configuration. This reflects the system, global, and workspace-local configuration values, and allows you to read, write, and delete configuration options from any or all of these locations.
- `west.commands.WestCommand`:
  - `config`: new attribute, returns a `Configuration` object or aborts the program if none is set. This is always usable from within extension command `do_run()` implementations.
  - `has_config`: new boolean attribute, which is `True` if and only if reading `self.config` will abort the program.
- The path handling in the `west.manifest` package has been overhauled in a backwards-incompatible way. For more details, see commit [56cfe8d1d1](https://github.com/zephyrproject-rtos/west/commit/56cfe8d1d1f3c9b45de3e793c738acd62db52aca).
- `west.manifest.Manifest.validate()`: this now returns the validated data as a Python dict. This can be useful if the value passed to this function was a str, and the dict is desired.
- `west.manifest.Manifest`: new:
  - path attributes `abspath`, `posixpath`, `relative_path`, `yaml_path`, `repo_path`, `repo_posixpath`

  - `userdata` attribute, which contains the parsed value from `manifest: self: userdata:`, or is None
  - `from_topdir()` factory method
- `west.manifest.ManifestProject`: new `userdata` attribute, which also contains the parsed value from `manifest: self: userdata:`, or is None
- `west.manifest.ManifestImportFailed`: the constructor can now take any value; this can be used to reflect failed imports from a *map* or other compound value.
- Deprecated configuration APIs:

  The following APIs are now deprecated in favor of using a `Configuration` object. Usually this will be done via `self.config` from a `WestCommand` instance, but this can be done directly by instantiating a `Configuration` object for other usages.

  - `west.configuration.config`
  - `west.configuration.read_config`
  - `west.configuration.update_config`
  - `west.configuration.delete_config`

v0.12.0

New features:

- West now works on the MSYS2 platform.
- West manifest files can now contain arbitrary user data associated with each project. See *Repository user data* for details.

Bug fixes:

- The `west list` command's `{sha}` format key has been fixed for the manifest repository; it now prints `N/A` ("not applicable") as expected.

API changes:

- The `west.manifest.Project.userdata` attribute was added to support project user data.

v0.11.1

New features:

- `west status` now only prints output for projects which have a nonempty status.

Bug fixes:

- The manifest file parser was incorrectly allowing project names which contain the path separator characters `/` and `\`. These invalid characters are now rejected.

  Note: if you need to place a project within a subdirectory of the workspace topdir, use the `path:` key. If you need to customize a project's fetch URL relative to its remote `url-base:`, use `repo-path:`. See *Projects* for examples.
- The changes made in west v0.10.1 to the `west init --manifest-rev` option which selected the default branch name were leaving the manifest repository in a detached HEAD state. This has been fixed by using `git clone` internally instead of `git init` and `git fetch`. See issue #522 for details.
- The `WEST_CONFIG_LOCAL` environment variable now correctly overrides the default location, `<workspace topdir>/.west/config`.

- `west update --fetch=smart` (`smart` is the default) now correctly skips fetches for project revisions which are lightweight tags (it already worked correctly for annotated tags; only lightweight tags were unnecessarily fetched).

Other changes:

- The fix for issue #522 mentioned above introduces a new restriction. The `west init --manifest-rev` option value, if given, must now be either a branch or a tag. In particular, "pseudo-branches" like GitHub's `pull/1234/head` references which could previously be used to fetch a pull request can no longer be passed to `--manifest-rev`. Users must now fetch and check out such revisions manually after running `west init`.

API changes:

- `west.manifest.Manifest.get_projects()` avoids incorrect results in some edge cases described in issue #523.
- `west.manifest.Project.sha()` now works correctly for tag revisions. (This applies to both lightweight and annotated tags.)

v0.11.0

New features:

- `west update` now supports `--narrow`, `--name-cache`, and `--path-cache` options. These can be influenced by the `update.narrow`, `update.name-cache`, and `update.path-cache` *Configuration* options. These can be used to optimize the speed of the update.
- `west update` now supports a `--fetch-opt` option that will be passed to the `git fetch` command used to fetch remote revisions when updating each project.

Bug fixes:

- `west update` now synchronizes Git submodules in projects by default. This avoids issues if the URL changes in the manifest file from when the submodule was first initialized. This behavior can be disabled by setting the `update.sync-submodules` configuration option to `false`.

Other changes:

- the west-apis-manifest module has fixed docstrings for the Project class

v0.10.1

New features:

- The *west init* command's `--manifest-rev` (`--mr`) option no longer defaults to `master`. Instead, the command will query the repository for its default branch name and use that instead. This allows users to move from `master` to `main` without breaking scripts that do not provide this option.

v0.10.0

New features:

- The `name` key in a project's *submodules list* is now optional.

Bug fixes:

- West now checks that the manifest schema version is one of the explicitly allowed values documented in *Version*. The old behavior was just to check that the schema version was

newer than the west version where the `manifest: version:` key was introduced. This incorrectly allowed invalid schema versions, like `0.8.2`.

Other changes:

- A manifest file's `group-filter` is now propagated through an `import`. This is a change from how west v0.9.x handled this. In west v0.9.x, only the top level manifest file's `group-filter` had any effect; the group filter lists from any imported manifests were ignored.

  Starting with west v0.10.0, the group filter lists from imported manifests are also imported. For details, see *Group Filters and Imports*.

  The new behavior will take effect if `manifest: version:` is not given or is at least `0.10`. The old behavior is still available in the top level manifest file only with an explicit `manifest: version: 0.9`. See *Version* for more information on schema versions.

  See west pull request #482 for the motivation for this change and additional context.

v0.9.1

Bug fixes:

- Commands like `west manifest --resolve` now correctly include group and group filter information.

Other changes:

- West now warns if you combine `import` with `group-filter`. Semantics for this combination have changed starting with v0.10.x. See the v0.10.0 release notes above for more information.

v0.9.0

Warning

The `west config` fix described below comes at a cost: any comments or other manual edits in configuration files will be removed when setting a configuration option via that command or the `west.configuration` API.

Warning

Combining the `group-filter` feature introduced in this release with manifest imports is discouraged. The resulting behavior has changed in west v0.10.

New features:

- West manifests now support *Git Submodules in Projects*. This allows you to clone Git submodules into a west project repository in addition to the project repository itself.
- West manifests now support *Project Groups*. Project groups can be enabled and disabled to determine what projects are "active", and therefore will be acted upon by the following commands: `west update`, `west list`, `west diff`, `west status`, `west forall`.
- `west update` no longer updates inactive projects by default. It now supports a `--group-filter` option which allows for one-time modifications to the set of enabled and disabled project groups.

- Running `west list`, `west diff`, `west status`, or `west forall` with no arguments does not print information for inactive projects by default. If the user specifies a list of projects explicitly at the command line, output for them is included regardless of whether they are active.

  These commands also now support `--all` arguments to include all projects, even inactive ones.

- `west list` now supports a `{groups}` format string key in its `--format` argument.

Bug fixes:

- The `west config` command and `west.configuration` API did not correctly store some configuration values, such as strings which contain commas. This has been fixed; see commit 36f3f91e for details.
- A manifest file with an empty `manifest: self: path:` value is invalid, but west used to let it pass silently. West now rejects such manifests.
- A bug affecting the behavior of the `west init -l .` command was fixed; see issue #435.

API changes:

- added `west.manifest.Manifest.is_active()`
- added `west.manifest.Manifest.group_filter`
- added `submodules` attribute to `west.manifest.Project`, which has newly added type `west.manifest.Submodule`

Other changes:

- The *Manifest Imports* feature now supports the terms `allowlist` and `blocklist` instead of `whitelist` and `blacklist`, respectively.

  The old terms are still supported for compatibility, but the documentation has been updated to use the new ones exclusively.

v0.8.0

This is a feature release which changes the manifest schema by adding support for a `path-prefix:` key in an `import:` mapping, along with some other features and fixes.

- Manifest import mappings now support a `path-prefix:` key, which places the project and its imported repositories in a subdirectory of the workspace. See *Example 3.4: Import into a subdirectory* for an example.
- The west command line application can now also be run using `python3 -m west`. This makes it easier to run west under a particular Python interpreter without modifying the *PATH* environment variable.
- *west manifest –path* prints the absolute path to west.yml
- `west init` now supports an `--mf foo.yml` option, which initializes the workspace using `foo.yml` instead of `west.yml`.
- `west list` now prints the manifest repository's path using the `manifest.path` *configuration option*, which may differ from the `self: path:` value in the manifest data. The old behavior is still available, but requires passing a new `--manifest-path-from-yaml` option.
- Various Python API changes; see west-apis for details.

v0.7.3

This is a bugfix release.

- Fix an error where a failed import could leave the workspace in an unusable state (see [PR #415](https://github.com/zephyrproject-rtos/west/pull/415) for details)

v0.7.2

This is a bugfix and minor feature release.

- Filter out duplicate extension commands brought in by manifest imports
- Fix `west.Manifest.get_projects()` when finding the manifest repository by path

v0.7.1

This is a bugfix and minor feature release.

- `west update --stats` now prints timing for operations which invoke a subprocess, time spent in west's Python process for each project, and total time updating each project.
- `west topdir` always prints a POSIX style path
- minor console output changes

v0.7.0

The main user-visible feature in west 0.7 is the *Manifest Imports* feature. This allows users to load west manifest data from multiple different files, resolving the results into a single logical manifest.

Additional user-visible changes:

- The idea of a "west installation" has been renamed to "west workspace" in this documentation and in the west API documentation. The new term seems to be easier for most people to work with than the old one.
- West manifests now support a *schema version*.
- The "west config" command can now be run outside of a workspace, e.g. to run `west config --global section.key value` to set a configuration option's value globally.
- There is a new *west topdir* command, which prints the root directory of the current west workspace.
- The `west -vv init` command now prints the git operations being performed, and their results.
- The restriction that no project can be named "manifest" is now enforced; the name "manifest" is reserved for the manifest repository, and is usable as such in commands like `west list manifest`, instead of `west list path-to-manifest-repository` being the only way to say that
- It's no longer an error if there is no project named "zephyr". This is part of an effort to make west generally usable for non-Zephyr use cases.
- Various bug fixes.

The developer-visible changes to the west-apis are:

- west.build and west.cmake: deprecated; this is Zephyr-specific functionality and should never have been part of west. Since Zephyr v1.14 LTS relies on it, it will continue to be included in the distribution, but will be removed when that version of Zephyr is obsoleted.
- west.commands:
  - WestCommand.requires_installation: deprecated; use requires_workspace instead

  - WestCommand.requires_workspace: new
  - WestCommand.has_manifest: new
  - WestCommand.manifest: this is now settable
- west.configuration: callers can now identify the workspace directory when reading and writing configuration files
- west.log:
  - msg(): new
- west.manifest:
  - The module now uses the standard logging module instead of west.log
  - QUAL_REFS_WEST: new
  - SCHEMA_VERSION: new
  - Defaults: removed
  - Manifest.as_dict(): new
  - Manifest.as_frozen_yaml(): new
  - Manifest.as_yaml(): new
  - Manifest.from_file() and from_data(): these factory methods are more flexible to use and less reliant on global state
  - Manifest.validate(): new
  - ManifestImportFailed: new
  - ManifestProject: semi-deprecated and will likely be removed later.
  - Project: the constructor now takes a topdir argument
  - Project.format() and its callers are removed. Use f-strings instead.
  - Project.name_and_path: new
  - Project.remote_name: new
  - Project.sha() now captures stderr
  - Remote: removed

West now requires Python 3.6 or later. Additionally, some features may rely on Python dictionaries being insertion-ordered; this is only an implementation detail in CPython 3.6, but it is part of the language specification as of Python 3.7.

v0.6.3

This point release fixes an error in the behavior of the deprecated `west.cmake` module.

v0.6.2

This point release fixes an error in the behavior of `west update --fetch=smart`, introduced in v0.6.1.

All v0.6.1 users must upgrade.

v0.6.1

Warning

Do not use this point release. Make sure to use v0.6.2 instead.

The user-visible features in this point release are:

- The *west update* command has a new `--fetch` command line flag and `update.fetch` *configuration option*. The default value, "smart", skips fetching SHAs and tags which are available locally.
- Better and more consistent error-handling in the `west diff`, `west status`, `west forall`, and `west update` commands. Each of these commands can operate on multiple projects; if a subprocess related to one project fails, these commands now continue to operate on the rest of the projects. All of them also now report a nonzero error code from the west process if any of these subprocesses fails (this was previously not true of `west forall` in particular).
- The *west manifest* command also handles errors better.
- The *west list* command now works even when the projects are not cloned, as long as its format string only requires information which can be read from the manifest file. It still fails if the format string requires data stored in the project repository, e.g. if it includes the `{sha}` format string key.
- Commands and options which operate on git revisions now accept abbreviated SHAs. For example, `west init --mr SHA_PREFIX` now works. Previously, the `--mr` argument needed to be the entire 40 character SHA if it wasn't a branch or a tag.

The developer-visible changes to the west-apis are:

- west.log.banner(): new
- west.log.small_banner(): new
- west.manifest.Manifest.get_projects(): new
- west.manifest.Project.is_cloned(): new
- west.commands.WestCommand instances can now access the parsed Manifest object via a new self.manifest property during the do_run() call. If read, it returns the Manifest object or aborts the command if it could not be parsed.
- west.manifest.Project.git() now has a capture_stderr kwarg

v0.6.0

- No separate bootstrapper

  In west v0.5.x, the program was split into two components, a bootstrapper and a per-installation clone. See Multiple Repository Management in the v1.14 documentation for more details.

  This is similar to how Google's Repo tool works, and lets west iterate quickly at first. It caused confusion, however, and west is now stable enough to be distributed entirely as one piece via PyPI.

  From v0.6.x onwards, all of the core west commands and helper classes are part of the west package distributed via PyPI. This eliminates complexity and makes it possible to import west modules from anywhere in the system, not just extension commands.

- The `selfupdate` command still exists for backwards compatibility, but now simply exits after printing an error message.
- Manifest syntax changes
  - A west manifest file's `projects` elements can now specify their fetch URLs directly, like so:

```
manifest:
  projects:
    - name: example-project-name
      url: https://github.com/example/example-project
```

    Project elements with `url` attributes set in this way may not also have `remote` attributes.
  - Project names must be unique: this restriction is needed to support future work, but was not possible in west v0.5.x because distinct projects may have URLs with the same final pathname component, like so:

```
manifest:
  remotes:
    - name: remote-1
      url-base: https://github.com/remote-1
    - name: remote-2
      url-base: https://github.com/remote-2
  projects:
    - name: project
      remote: remote-1
      path: remote-1-project
    - name: project
      remote: remote-2
      path: remote-2-project
```

    These manifests can now be written with projects that use `url` instead of `remote`, like so:

```
manifest:
  projects:
    - name: remote-1-project
      url: https://github.com/remote-1/project
    - name: remote-2-project
      url: https://github.com/remote-2/project
```

- The `west list` command now supports a `{sha}` format string key
- The default format string for `west list` was changed to `"{name:12} {path:28} {revision:40} {url}"`.
- The command `west manifest --validate` can now be run to load and validate the current manifest file, among other error-handling fixes related to manifest parsing.
- Incompatible API changes were made to west's APIs. Further changes are expected until API stability is declared in west v1.0.
  - The `west.manifest.Project` constructor's `remote` and `defaults` positional arguments are now kwargs. A new `url` kwarg was also added; if given, the `Project` URL is set to that value, and the `remote` kwarg is ignored.
  - `west.manifest.MANIFEST_SECTIONS` was removed. There is only one section now, namely `manifest`. The *sections* kwargs in the `west.manifest.Manifest` factory methods and constructor were also removed.
  - The `west.manifest.SpecialProject` class was removed. Use `west.manifest.ManifestProject` instead.

v0.5.x

West v0.5.x is the first version used widely by the Zephyr Project as part of its v1.14 Long-Term Support (LTS) release. The west v0.5.x documentation is available as part of the Zephyr's v1.14 documentation.

West's main features in v0.5.x are:

- Multiple repository management using Git repositories, including self-update of west itself
- Hierarchical configuration files
- Extension commands

Versions Before v0.5.x

Tags in the west repository before v0.5.x are prototypes which are of historical interest only.

2.11.3 Troubleshooting West

This page covers common issues with west and how to solve them.

`west update` fetching failures

One good way to troubleshoot fetching issues is to run `west update` in verbose mode, like this:

```
west -v update
```

The output includes Git commands run by west and their outputs. Look for something like this:

```
=== updating your_project (path/to/your/project):
west.manifest: your_project: checking if cloned
[...other west.manifest logs...]
--- your_project: fetching, need revision SOME_SHA
west.manifest: running 'git fetch ... https://github.com/your-username/your_project ...' in␣
↪/some/directory
```

The `git fetch` command example in the last line above is what needs to succeed.

One strategy is to go to `/path/to/your/project`, copy/paste and run the entire `git fetch` command, then debug from there using the documentation for your credential storage helper.

If you're behind a corporate firewall and may have proxy or other issues, `curl -v FETCH_URL` (for HTTPS URLs) or `ssh -v FETCH_URL` (for SSH URLs) may be helpful.

If you can get the `git fetch` command to run successfully without prompting for a password when you run it directly, you will be able to run `west update` without entering your password in that same shell.

"'west' is not recognized as an internal or external command, operable program or batch file."

On Windows, this means that either west is not installed, or your *PATH* environment variable does not contain the directory where pip installed `west.exe`.

First, make sure you've installed west; see *Installing west*. Then try running `west` from a new `cmd.exe` window. If that still doesn't work, keep reading.

You need to find the directory containing `west.exe`, then add it to your *PATH*. (This *PATH* change should have been done for you when you installed Python and pip, so ordinarily you should not need to follow these steps.)

Run this command in `cmd.exe`:

```
pip3 show west
```

Then:

1. Look for a line in the output that looks like `Location: C:\foo\python\python38\lib\site-packages`. The exact location will be different on your computer.
2. Look for a file named `west.exe` in the `scripts` directory `C:\foo\python\python38\scripts`.

   Important

   Notice how `lib\site-packages` in the `pip3 show` output was changed to `scripts`!

3. If you see `west.exe` in the `scripts` directory, add the full path to `scripts` to your *PATH* using a command like this:

   ```
   setx PATH "%PATH%;C:\foo\python\python38\scripts"
   ```

   Do not just copy/paste this command. The `scripts` directory location will be different on your system.

4. Close your `cmd.exe` window and open a new one. You should be able to run `west`.

"Error: unexpected keyword argument 'requires_workspace'"

This error occurs on some Linux distributions after upgrading to west 0.7.0 or later from 0.6.x. For example:

```
$ west update
[... stack trace ...]
TypeError: __init__() got an unexpected keyword argument 'requires_workspace'
```

This appears to be a problem with the distribution's pip; see this comment in west issue 373 for details. Some versions of **Ubuntu** and **Linux Mint** are known to have this problem. Some users report issues on Fedora as well.

Neither macOS nor Windows users have reported this issue. There have been no reports of this issue on other Linux distributions, like Arch Linux, either.

Workaround 1: remove the old version, then upgrade:

```
$ pip3 show west | grep Location: | cut -f 2 -d ' '
/home/foo/.local/lib/python3.6/site-packages
$ rm -r /home/foo/.local/lib/python3.6/site-packages/west
$ pip3 install --user west==0.7.0
```

Workaround 2: install west in a Python virtual environment

One option is to use the venv module that's part of the Python 3 standard library. Some distributions remove this module from their base Python 3 packages, so you may need to do some additional work to get it installed on your system.

"invalid choice: 'build'" (or 'flash', etc.)

If you see an unexpected error like this when trying to run a Zephyr extension command (like *west flash*, *west build*, etc.):

```
$ west build [...]
west: error: argument <command>: invalid choice: 'build' (choose from 'init', [...])

$ west flash [...]
west: error: argument <command>: invalid choice: 'flash' (choose from 'init', [...])
```

The most likely cause is that you're running the command outside of a *west workspace*. West needs to know where your workspace is to find *Extensions*.

To fix this, you have two choices:

1. Run the command from inside a workspace (e.g. the `zephyrproject` directory you created when you *got started*).

   For example, create your build directory inside the workspace, or run `west flash --build-dir YOUR_BUILD_DIR` from inside the workspace.

2. Set the *ZEPHYR_BASE environment variable* and re-run the west extension command. If set, west will use *ZEPHYR_BASE* to find your workspace.

If you're unsure whether a command is built-in or an extension, run `west help` from inside your workspace. The output prints extension commands separately, and looks like this for mainline Zephyr:

```
$ west help

built-in commands for managing git repositories:
  init:                 create a west workspace
  [...]

other built-in commands:
  help:                 get help for west or a command
  [...]

extension commands from project manifest (path: zephyr):
  build:                compile a Zephyr application
  flash:                flash and run a binary on a board
  [...]
```

"invalid choice: 'post-init'"

If you see this error when running `west init`:

```
west: error: argument <command>: invalid choice: 'post-init'
(choose from 'init', 'update', 'list', 'manifest', 'diff',
'status', 'forall', 'config', 'selfupdate', 'help')
```

Then you have an old version of west installed, and are trying to use it in a workspace that requires a more recent version.

The easiest way to resolve this issue is to upgrade west and retry as follows:

1. Install the latest west with the `-U` option for `pip3 install` as shown in *Installing west*.
2. Back up any contents of `zephyrproject/.west/config` that you want to save. (If you don't have any configuration options set, it's safe to skip this step.)
3. Completely remove the `zephyrproject/.west` directory (if you don't, you will get the "already in a workspace" error message discussed next).

4. Run `west init` again.

"already in an installation"

You may see this error when running `west init` with west 0.6:

```
FATAL ERROR: already in an installation (<some directory>), aborting
```

If this is unexpected and you're really trying to create a new west workspace, then it's likely that west is using the *ZEPHYR_BASE environment variable* to locate a workspace elsewhere on your system.

This is intentional; it allows you to put your Zephyr applications in any directory and still use west to build, flash, and debug them, for example.

To resolve this issue, unset *ZEPHYR_BASE* and try again.

2.11.4 Basics

This page introduces west's basic concepts and provides references to further reading.

West's built-in commands allow you to work with *projects* (Git repositories) under a common *workspace* directory.

West works in the following manner: the `west init` command creates the *west workspace*, and clones the *manifest repo*, while the `west update` command initially clones, and later updates, the *projects* listed in the manifest in the workspace.

Example workspace

If you've followed the *Getting Started Guide*, your local *west workspace*, which in this case is the folder named `zephyrproject` as well as all its subfolders, looks like this:

```
zephyrproject/                # west topdir
├── .west/                    # marks the location of the topdir
│   └── config                # per-workspace local configuration file
│
│   # The manifest repository, never modified by west after creation:
├── zephyr/                   # .git/ repo
│   ├── west.yml              # manifest file
│   └── [... other files ...]
│
│   # Projects managed by west:
├── modules/
│   └── lib/
│       └── zcbor/            # .git/ project
├── net-tools/                # .git/ project
└── [ ... other projects ...]
```

Workspace concepts

Here are the basic concepts you should understand about this structure. Additional details are in *Workspaces*.

topdir
: Above, `zephyrproject` is the name of the workspace's top level directory, or *topdir*. (The

name `zephyrproject` is just an example – it could be anything, like `z`, `my-zephyr-workspace`, etc.)

You'll typically create the topdir and a few other files and directories using *west init*.

.west directory
The topdir contains the `.west` directory. When west needs to find the topdir, it searches for `.west`, and uses its parent directory. The search starts from the current working directory (and starts again from the location in the *ZEPHYR_BASE* environment variable as a fallback if that fails).

configuration file
The file `.west/config` is the workspace's *local configuration file*.

manifest repository
Every west workspace contains exactly one *manifest repository*, which is a Git repository containing a *manifest file*. The location of the manifest repository is given by the *manifest.path configuration option* in the local configuration file.

For upstream Zephyr, `zephyr` is the manifest repository, but you can configure west to use any Git repository in the workspace as the manifest repository. The only requirement is that it contains a valid manifest file. See *Topologies supported* for information on other options, and *West Manifests* for details on the manifest file format.

manifest file
The manifest file is a YAML file that defines *projects*, which are the additional Git repositories in the workspace managed by west. The manifest file is named `west.yml` by default; this can be overridden using the `manifest.file` local configuration option.

You use the *west update* command to update the workspace's projects based on the contents of the manifest file.

projects
Projects are Git repositories managed by west. Projects are defined in the manifest file and can be located anywhere inside the workspace. In the above example workspace, `zcbor` and `net-tools` are projects.

By default, the Zephyr *build system* uses west to get the locations of all the projects in the workspace, so any code they contain can be used as *Modules (External projects)*. Note however that modules and projects *are conceptually different*.

extensions
Any repository known to west (either the manifest repository or any project repository) can define *Extensions*. Extensions are extra west commands you can run when using that workspace.

The zephyr repository uses this feature to provide Zephyr-specific commands like *west build*. Defining these as extensions keeps west's core agnostic to the specifics of any workspace's Zephyr version, etc.

ignored files
A workspace can contain additional Git repositories or other files and directories not managed by west. West basically ignores anything in the workspace except `.west`, the manifest repository, and the projects specified in the manifest file.

west init and west update

The two most important workspace-related commands are `west init` and `west update`.

`west init` basics This command creates a west workspace.

Important

West doesn't change your manifest repository contents after `west init` is run. Use ordinary Git commands to pull new versions, etc.

You will typically run it once, like this:

```
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v2.5.0 zephyrproject
```

This will:

1. Create the topdir, `zephyrproject`, along with `.west` and `.west/config` inside it
2. Clone the manifest repository from https://github.com/zephyrproject-rtos/zephyr, placing it into `zephyrproject/zephyr`
3. Check out the `v2.5.0` git tag in your local zephyr clone
4. Set `manifest.path` to `zephyr` in `.west/config`
5. Set `manifest.file` to `west.yml`

Your workspace is now almost ready to use; you just need to run `west update` to clone the rest of the projects into the workspace to finish.

For more details, see *west init*.

`west update` basics This command makes sure your workspace contains Git repositories matching the projects in the manifest file.

Important

Whenever you check out a different revision in your manifest repository, you should run `west update` to make sure your workspace contains the project repositories the new revision expects.

The `west update` command reads the manifest file's contents by:

1. Finding the topdir. In the `west init` example above, that means finding `zephyrproject`.
2. Loading `.west/config` in the topdir to read the `manifest.path` (e.g. `zephyr`) and `manifest.file` (e.g. `west.yml`) options.
3. Loading the manifest file given by these options (e.g. `zephyrproject/zephyr/west.yml`).

It then uses the manifest file to decide where missing projects should be placed within the workspace, what URLs to clone them from, and what Git revisions should be checked out locally. Project repositories which already exist are updated in place by fetching and checking out their respective Git revisions in the manifest file.

For more details, see *west update*.

Other built-in commands

See *Built-in commands*.

Zephyr Extensions

See the following pages for information on Zephyr's extension commands:

- *Building, Flashing and Debugging*
- *Signing Binaries*
- *Additional Zephyr extension commands*
- *Enabling shell completion*

Troubleshooting

See *Troubleshooting West*.

2.11.5 Built-in commands

This page describes west's built-in commands, some of which were introduced in *Basics*, in more detail.

Some commands are related to Git commands with the same name, but operate on the entire workspace. For example, `west diff` shows local changes in multiple Git repositories in the workspace.

Some commands take projects as arguments. These arguments can be project names as specified in the manifest file, or (as a fallback) paths to them on the local file system. Omitting project arguments to commands which accept them (such as `west list`, `west forall`, etc.) usually defaults to using all projects in the manifest file plus the manifest repository itself.

For additional help, run `west <command> -h` (e.g. `west init -h`).

west init

This command creates a west workspace. It can be used in two ways:

1. Cloning a new manifest repository from a remote URL
2. Creating a workspace around an existing local manifest repository

Option 1: to clone a new manifest repository from a remote URL, use:

```
west init [-m URL] [--mr REVISION] [--mf FILE] [directory]
```

The new workspace is created in the given `directory`, creating a new `.west` inside this directory. You can give the manifest URL using the `-m` switch, the initial revision to check out using `--mr`, and the location of the manifest file within the repository using `--mf`.

For example, running:

```
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v1.14.0 zp
```

would clone the upstream official zephyr repository into `zp/zephyr`, and check out the `v1.14.0` release. This command creates `zp/.west`, and set the `manifest.path` *configuration option* to `zephyr` to record the location of the manifest repository in the workspace. The default manifest file location is used.

The `-m` option defaults to `https://github.com/zephyrproject-rtos/zephyr`. The `--mf` option defaults to `west.yml`. Since west v0.10.1, west will use the default branch in the manifest repository unless the `--mr` option is used to override it. (In prior versions, `--mr` defaulted to `master`.)

If no `directory` is given, the current working directory is used.

Option 2: to create a workspace around an existing local manifest repository, use:

```
west init -l [--mf FILE] directory
```

This creates `.west` **next to** `directory` in the file system, and sets `manifest.path` to `directory`.

As above, `--mf` defaults to `west.yml`.

Reconfiguring the workspace:

If you change your mind later, you are free to change `manifest.path` and `manifest.file` using *west config* after running `west init`. Just be sure to run `west update` afterwards to update your workspace to match the new manifest file.

west update

```
west update [-f {always,smart}] [-k] [-r]
            [--group-filter FILTER] [--stats] [PROJECT ...]
```

Which projects are updated:

By default, this command parses the manifest file, usually `west.yml`, and updates each project specified there. If your manifest uses *project groups*, then only the active projects are updated.

To operate on a subset of projects only, give `PROJECT` argument(s). Each `PROJECT` is either a project name as given in the manifest file, or a path that points to the project within the workspace. If you specify projects explicitly, they are updated regardless of whether they are active.

Project update procedure:

For each project that is updated, this command:

1. Initializes a local Git repository for the project in the workspace, if it does not already exist
2. Inspects the project's `revision` field in the manifest, and fetches it from the remote if it is not already available locally
3. Sets the project's *manifest-rev* branch to the commit specified by the revision in the previous step
4. Checks out `manifest-rev` in the local working copy as a detached HEAD
5. If the manifest file specifies a *submodules* key for the project, recursively updates the project's submodules as described below.

To avoid unnecessary fetches, `west update` will not fetch project `revision` values which are Git SHAs or tags that are already available locally. This is the behavior when the `-f` (`--fetch`) option has its default value, `smart`. To force this command to fetch from project remotes even if the revisions appear to be available locally, either use `-f always` or set the `update.fetch` *configuration option* to `always`. SHAs may be given as unique prefixes as long as they are acceptable to Git[1].

If the project `revision` is a Git ref that is neither a tag nor a SHA (i.e. if the project is tracking a branch), `west update` always fetches, regardless of `-f` and `update.fetch`.

Some branch names might look like short SHAs, like `deadbeef`. West treats these like SHAs. You can disambiguate by prefixing the `revision` value with `refs/heads/`, e.g. `revision: refs/heads/deadbeef`.

For safety, `west update` uses `git checkout --detach` to check out a detached `HEAD` at the manifest revision for each updated project, leaving behind any branches which were already checked out. This is typically a safe operation that will not modify any of your local branches.

However, if you had added some local commits onto a previously detached `HEAD` checked out by west, then git will warn you that you've left behind some commits which are no longer referred

[1] West may fetch all refs from the Git server when given a SHA as a revision. This is because some Git servers have historically not allowed fetching SHAs directly.

to by any branch. These may be garbage-collected and lost at some point in the future. To avoid this if you have local commits in the project, make sure you have a local branch checked out before running `west update`.

If you would rather rebase any locally checked out branches instead, use the `-r` (`--rebase`) option.

If you would like `west update` to keep local branches checked out as long as they point to commits that are descendants of the new `manifest-rev`, use the `-k` (`--keep-descendants`) option.

Note

`west update --rebase` will fail in projects that have git conflicts between your branch and new commits brought in by the manifest. You should immediately resolve these conflicts as you usually do with `git`, or you can use `git -C <project_path> rebase --abort` to ignore incoming changes for the moment.

With a clean working tree, a plain `west update` never fails because it does not try to hold on to your commits and simply leaves them aside.

`west update --keep-descendants` offers an intermediate option that never fails either but does not treat all projects the same:

- in projects where your branch diverged from the incoming commits, it does not even try to rebase and leaves your branches behind just like a plain `west update` does;
- in all other projects where no rebase or merge is needed it keeps your branches in place.

One-time project group manipulation:

The `--group-filter` option can be used to change which project groups are enabled or disabled for the duration of a single `west update` command. See *Project Groups* for details on the project group feature.

The `west update` command behaves as if the `--group-filter` option's value were appended to the `manifest.group-filter` *configuration option*.

For example, running `west update --group-filter=+foo,-bar` would behave the same way as if you had temporarily appended the string `"+foo,-bar"` to the value of `manifest.group-filter`, run `west update`, then restored `manifest.group-filter` to its original value.

Note that using the syntax `--group-filter=VALUE` instead of `--group-filter VALUE` avoids issues parsing command line options if you just want to disable a single group, e.g. `--group-filter=-bar`.

Submodule update procedure:

If a project in the manifest has a `submodules` key, the submodules are updated as follows, depending on the value of the `submodules` key.

If the project has `submodules: true`, west first synchronizes the project's submodules with:

```
git submodule sync --recursive
```

West then runs one of the following in the project repository, depending on whether you run `west update` with the `--rebase` option or without it:

```
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive
```

Otherwise, the project has `submodules: <list-of-submodules>`. In this case, west synchronizes the project's submodules with:

```
git submodule sync --recursive -- <submodule-path>
```

Then it updates each submodule in the list as follows, depending on whether you run `west update` with the `--rebase` option or without it:

```
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive <submodule-path>

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive <submodule-path>
```

The `git submodule sync` commands are skipped if the `update.sync-submodules` *Configuration* option is false.

Other project commands

West has a few more commands for managing the projects in the workspace, which are summarized here. Run `west <command> -h` for detailed help.

- `west compare`: compare the state of the workspace against the manifest
- `west diff`: run `git diff` in local project repositories
- `west forall`: run an arbitrary command in local project repositories
- `west grep`: search for patterns in local project repositories
- `west list`: print a line of information about each project in the manifest, according to a format string
- `west manifest`: manage the manifest file. See *Manifest Command*.
- `west status`: run `git status` in local project repositories

Other built-in commands

Finally, here is a summary of other built-in commands.

- `west config`: get or set *configuration options*
- `west topdir`: print the top level directory of the west workspace
- `west help`: get help about a command, or print information about all commands in the workspace, including *Extensions*

2.11.6 Workspaces

This page describes the *west workspace* concept introduced in *Basics* in more detail.

The `manifest-rev` branch

West creates and controls a Git branch named `manifest-rev` in each project. This branch points to the revision that the manifest file specified for the project at the time *west update* was last run. Other workspace management commands may use `manifest-rev` as a reference point for the upstream revision as of this latest update. Among other purposes, the `manifest-rev` branch allows the manifest file to use SHAs as project revisions.

Although `manifest-rev` is a normal Git branch, west will recreate and/or reset it on the next update. For this reason, it is **dangerous** to check it out or otherwise modify it yourself. For

instance, any commits you manually add to this branch may be lost the next time you run `west update`. Instead, check out a local branch with another name, and either rebase it on top of a new `manifest-rev`, or merge `manifest-rev` into it.

Note

West does not create a `manifest-rev` branch in the manifest repository, since west does not manage the manifest repository's branches or revisions.

The `refs/west/*` Git refs

West also reserves all Git refs that begin with `refs/west/` (such as `refs/west/foo`) for itself in local project repositories. Unlike `manifest-rev`, these refs are not regular branches. West's behavior here is an implementation detail; users should not rely on these refs' existence or behavior.

Private repositories

You can use west to fetch from private repositories. There is nothing west-specific about this.

The `west update` command essentially runs `git fetch YOUR_PROJECT_URL` when a project's `manifest-rev` branch must be updated to a newly fetched commit. It's up to your environment to make sure the fetch succeeds.

You can either enter the password manually or use any of the credential helpers built in to Git. Since Git has credential storage built in, there is no need for a west-specific feature.

The following sections cover common cases for running `west update` without having to enter your password, as well as how to troubleshoot issues.

Fetching via HTTPS On Windows when fetching from GitHub, recent versions of Git prompt you for your GitHub password in a graphical window once, then store it for future use (in a default installation). Passwordless fetching from GitHub should therefore work "out of the box" on Windows after you have done it once.

In general, you can store your credentials on disk using the "store" git credential helper. See the git-credential-store manual page for details.

To use this helper for all the repositories in your workspace, run:

```
west forall -c "git config credential.helper store"
```

To use this helper on just the projects `foo` and `bar`, run:

```
west forall -c "git config credential.helper store" foo bar
```

To use this helper by default on your computer, run:

```
git config --global credential.helper store
```

On GitHub, you can set up a personal access token to use in place of your account password. (This may be required if your account has two-factor authentication enabled, and may be preferable to storing your account password in plain text even if two-factor authentication is disabled.)

You can use the Git credential store to authenticate with a GitHub PAT (Personal Access Token) like so:

```
echo "https://x-access-token:$GH_TOKEN@github.com" >> ~/.git-credentials
```

If you don't want to store any credentials on the file system, you can store them in memory temporarily using git-credential-cache instead.

If you setup fetching via SSH, you can use Git URL rewrite feature. The following command instructs Git to use SSH URLs for GitHub instead of HTTPS ones:

```
git config --global url."git@github.com:".insteadOf "https://github.com/"
```

Fetching via SSH If your SSH key has no password, fetching should just work. If it does have a password, you can avoid entering it manually every time using ssh-agent.

On GitHub, see Connecting to GitHub with SSH for details on configuration and key creation.

Project locations

Projects can be located anywhere inside the workspace, but they may not "escape" it.

In other words, project repositories need not be located in subdirectories of the manifest repository or as immediate subdirectories of the topdir. However, projects must have paths inside the workspace.

You may replace a project's repository directory within the workspace with a symbolic link to elsewhere on your computer, but west will not do this for you.

Topologies supported

The following are example source code topologies supported by west.

- T1: star topology, zephyr is the manifest repository
- T2: star topology, a Zephyr application is the manifest repository
- T3: forest topology, freestanding manifest repository

T1: Star topology, zephyr is the manifest repository

- The zephyr repository acts as the central repository and specifies its *Modules (External projects)* in its `west.yml`
- Analogy with existing mechanisms: Git submodules with zephyr as the super-project

This is the default. See *Workspace concepts* for how mainline Zephyr is an example of this topology.

T2: Star topology, application is the manifest repository

- Useful for those focused on a single application
- A repository containing a Zephyr application acts as the central repository and names other projects required to build it in its `west.yml`. This includes the zephyr repository and any modules.
- Analogy with existing mechanisms: Git submodules with the application as the super-project, zephyr and other projects as submodules

A workspace using this topology looks like this:

```
west-workspace/
|
├── application/         # .git/     |
|   ├── CMakeLists.txt                |
|   ├── prj.conf                      |  never modified by west
|   ├── src/                          |
|   |   └── main.c                    |
|   └── west.yml         # main manifest with optional import(s) and override(s)
|                                     |
├── modules/
|   └── lib/
|       └── zcbor/       # .git/ project from either the main manifest or some import.
|
└── zephyr/              # .git/ project
    └── west.yml         # This can be partially imported with lower precedence or ignored.
                         # Only the 'manifest-rev' version can be imported.
```

Here is an example `application/west.yml` which uses *Manifest Imports*, available since west 0.7, to import Zephyr v2.5.0 and its modules into the application manifest file:

```
# Example T2 west.yml, using manifest imports.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.5.0
      import: true
  self:
    path: application
```

You can still selectively "override" individual Zephyr modules if you use `import:` in this way; see *Example 1.3: Downstream of a Zephyr release, with module fork* for an example.

Another way to do the same thing is to copy/paste `zephyr/west.yml` to `application/west.yml`, adding an entry for the zephyr project itself, like this:

```
# Equivalent to the above, but with manually maintained Zephyr modules.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  defaults:
    remote: zephyrproject-rtos
  projects:
    - name: zephyr
      revision: v2.5.0
      west-commands: scripts/west-commands.yml
    - name: net-tools
      revision: some-sha-goes-here
      path: tools/net-tools
    # ... other Zephyr modules go here ...
  self:
    path: application
```

(The `west-commands` is there for *Building, Flashing and Debugging* and other Zephyr-specific *Extensions*. It's not necessary when using `import`.)

The main advantage to using `import` is not having to track the revisions of imported projects separately. In the above example, using `import` means Zephyr's *module* versions are automatically determined from the `zephyr/west.yml` revision, instead of having to be copy/pasted (and

maintained) on their own.

T3: Forest topology

- Useful for those supporting multiple independent applications or downstream distributions with no "central" repository
- A dedicated manifest repository which contains no Zephyr source code, and specifies a list of projects all at the same "level"
- Analogy with existing mechanisms: Google repo-based source distribution

A workspace using this topology looks like this:

```
west-workspace/
├── app1/               # .git/ project
│   ├── CMakeLists.txt
│   ├── prj.conf
│   └── src/
│       └── main.c
├── app2/               # .git/ project
│   ├── CMakeLists.txt
│   ├── prj.conf
│   └── src/
│       └── main.c
├── manifest-repo/      # .git/ never modified by west
│   └── west.yml        # main manifest with optional import(s) and override(s)
├── modules/
│   └── lib/
│       └── zcbor/      # .git/ project from either the main manifest or
│                       #       from some import
│
└── zephyr/             # .git/ project
    └── west.yml        # This can be partially imported with lower precedence or ignored.
                        # Only the 'manifest-rev' version can be imported.
```

Here is an example T3 `manifest-repo/west.yml` which uses *Manifest Imports*, available since west 0.7, to import Zephyr v2.5.0 and its modules, then add the `app1` and `app2` projects:

```
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
    - name: your-git-server
      url-base: https://git.example.com/your-company
  defaults:
    remote: your-git-server
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.5.0
      import: true
    - name: app1
      revision: SOME_SHA_OR_BRANCH_OR_TAG
    - name: app2
      revision: ANOTHER_SHA_OR_BRANCH_OR_TAG
  self:
    path: manifest-repo
```

You can also do this "by hand" by copy/pasting `zephyr/west.yml` as shown *above* for the T2 topology, with the same caveats.

2.11.7 West Manifests

This page contains detailed information about west's multiple repository model, manifest files, and the `west manifest` command. For API documentation on the `west.manifest` module, see west-apis-manifest. For a more general introduction and command overview, see *Basics*.

Multiple Repository Model

West's view of the repositories in a *west workspace*, and their history, looks like the following figure (though some parts of this example are specific to upstream Zephyr's use of west):

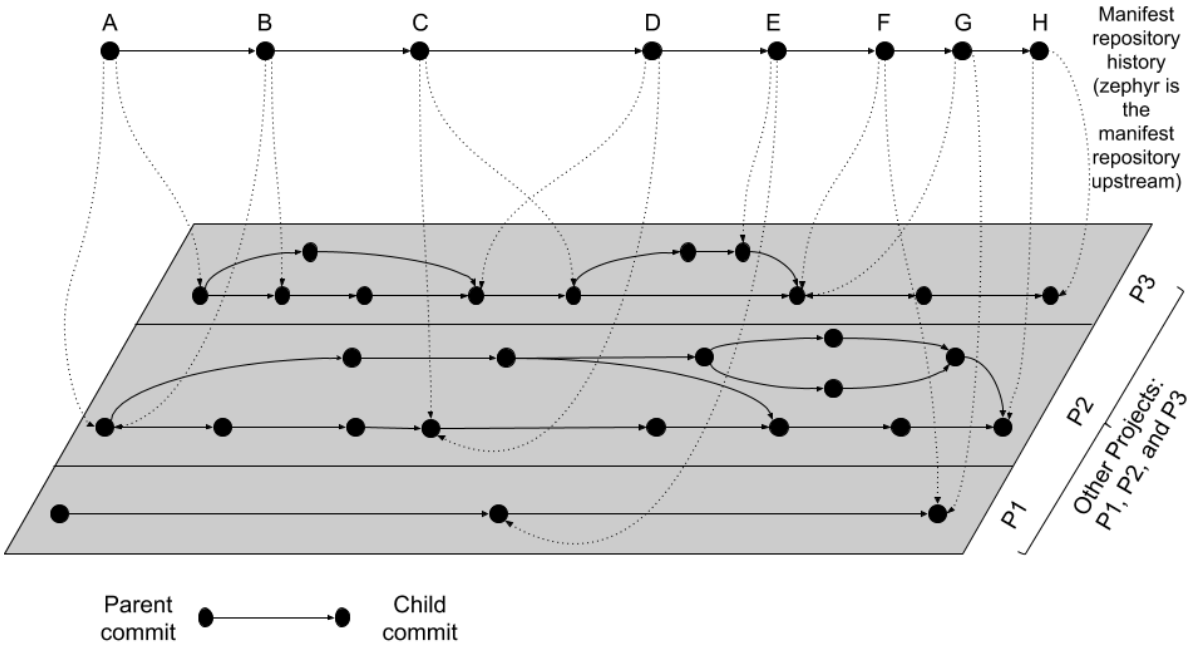

Fig. 3: West multi-repo history

The history of the manifest repository is the line of Git commits which is "floating" on top of the gray plane. Parent commits point to child commits using solid arrows. The plane below contains the Git commit history of the repositories in the workspace, with each project repository boxed in by a rectangle. Parent/child commit relationships in each repository are also shown with solid arrows.

The commits in the manifest repository (again, for upstream Zephyr this is the zephyr repository itself) each have a manifest file. The manifest file in each commit specifies the corresponding commits which it expects in each of the project repositories. This relationship is shown using dotted line arrows in the diagram. Each dotted line arrow points from a commit in the manifest repository to a corresponding commit in a project repository.

Notice the following important details:

- Projects can be added (like `P1` between manifest repository commits `D` and `E`) and removed (`P2` between the same manifest repository commits)
- Project and manifest repository histories don't have to move forwards or backwards together:
  - `P2` stays the same from `A` → `B`, as do `P1` and `P3` from `F` → `G`.
  - `P3` moves forward from `A` → `B`.
  - `P3` moves backward from `C` → `D`.

One use for moving backward in project history is to "revert" a regression by going back to a revision before it was introduced.

- Project repository commits can be "skipped": `P3` moves forward multiple commits in its history from `B → C`.
- In the above diagram, no project repository has two revisions "at the same time": every manifest file refers to exactly one commit in the projects it cares about. This can be relaxed by using a branch name as a manifest revision, at the cost of being able to bisect manifest repository history.

Manifest Files

West manifests are YAML files. Manifests have a top-level `manifest` section with some subsections, like this:

```
manifest:
  remotes:
    # short names for project URLs
  projects:
    # a list of projects managed by west
  defaults:
    # default project attributes
  self:
    # configuration related to the manifest repository itself,
    # i.e. the repository containing west.yml
  version: "<schema-version>"
  group-filter:
    # a list of project groups to enable or disable
```

In YAML terms, the manifest file contains a mapping, with a `manifest` key. Any other keys and their contents are ignored (west v0.5 also required a `west` key, but this is ignored starting with v0.6).

The manifest contains subsections, like `defaults`, `remotes`, `projects`, and `self`. In YAML terms, the value of the `manifest` key is also a mapping, with these "subsections" as keys. As of west v0.10, all of these "subsection" keys are optional.

The `projects` value is a list of repositories managed by west and associated metadata. We'll discuss it soon, but first we will describe the `remotes` section, which can be used to save typing in the `projects` list.

Remotes The `remotes` subsection contains a sequence which specifies the base URLs where projects can be fetched from.

Each `remotes` element has a name and a "URL base". These are used to form the complete Git fetch URL for each project. A project's fetch URL can be set by appending a project-specific path onto a remote URL base. (As we'll see below, projects can also specify their complete fetch URLs.)

For example:

```
manifest:
  # ...
  remotes:
    - name: remote1
      url-base: https://git.example.com/base1
    - name: remote2
      url-base: https://git.example.com/base2
```

The `remotes` keys and their usage are in the following table.

Table 2: remotes keys

Key	Description
name	Mandatory; a unique name for the remote.
url-base	A prefix that is prepended to the fetch URL for each project with this remote.

Above, two remotes are given, with names remote1 and remote2. Their URL bases are respectively https://git.example.com/base1 and https://git.example.com/base2. You can use SSH URL bases as well; for example, you might use git@example.com:base1 if remote1 supported Git over SSH as well. Anything acceptable to Git will work.

Projects The projects subsection contains a sequence describing the project repositories in the west workspace. Every project has a unique name. You can specify what Git remote URLs to use when cloning and fetching the projects, what revisions to track, and where the project should be stored on the local file system. Note that west projects *are different from modules*.

Here is an example. We'll assume the remotes given above.

```
manifest:
  # [... same remotes as above...]
  projects:
    - name: proj1
      description: the first example project
      remote: remote1
      path: extra/project-1
    - name: proj2
      description: |
        A multi-line description of the second example
        project.
      repo-path: my-path
      remote: remote2
      revision: v1.3
    - name: proj3
      url: https://github.com/user/project-three
      revision: abcde413a111
```

In this manifest:

- proj1 has remote remote1, so its Git fetch URL is https://git.example.com/base1/proj1. The remote url-base is appended with a / and the project name to form the URL.

  Locally, this project will be cloned at path extra/project-1 relative to the west workspace's root directory, since it has an explicit path attribute with this value.

  Since the project has no revision specified, master is used by default. The current tip of this branch will be fetched and checked out as a detached HEAD when west next updates this project.

- proj2 has a remote and a repo-path, so its fetch URL is https://git.example.com/base2/my-path. The repo-path attribute, if present, overrides the default name when forming the fetch URL.

  Since the project has no path attribute, its name is used by default. It will be cloned into a directory named proj2. The commit pointed to by the v1.3 tag will be checked out when west updates the project.

- proj3 has an explicit url, so it will be fetched from https://github.com/user/project-three.

  Its local path defaults to its name, proj3. Commit abcde413a111 will be checked out when it is next updated.

The available project keys and their usage are in the following table. Sometimes we'll refer to the `defaults` subsection; it will be described next.

Table 3: projects elements keys

Key(s)	Description
`name`	Mandatory; a unique name for the project. The name cannot be one of the reserved values "west" or "manifest". The name must be unique in the manifest file.
`description`	Optional, an informational description of the project. Added in west v1.2.0.
`remote`, `url`	Mandatory (one of the two, but not both). If the project has a `remote`, that remote's `url-base` will be combined with the project's `name` (or `repo-path`, if it has one) to form the fetch URL instead. If the project has a `url`, that's the complete fetch URL for the remote Git repository. If the project has neither, the `defaults` section must specify a `remote`, which will be used as the project's remote. Otherwise, the manifest is invalid.
`repo-path`	Optional. If given, this is concatenated on to the remote's `url-base` instead of the project's `name` to form its fetch URL. Projects may not have both `url` and `repo-path` attributes.
`revision`	Optional. The Git revision that `west update` should check out. This will be checked out as a detached HEAD by default, to avoid conflicting with local branch names. If not given, the `revision` value from the `defaults` subsection will be used if present. A project revision can be a branch, tag, or SHA. The default `revision` is `master` if not otherwise specified. Using `HEAD~0`[1] as the `revision` will cause west to keep the current state of the project.
`path`	Optional. Relative path specifying where to clone the repository locally, relative to the top directory in the west workspace. If missing, the project's `name` is used as a directory name.
`clone-depth`	Optional. If given, a positive integer which creates a shallow history in the cloned repository limited to the given number of commits. This can only be used if the `revision` is a branch or tag.
`west-commands`	Optional. If given, a relative path to a YAML file within the project which describes additional west commands provided by that project. This file is named `west-commands.yml` by convention. See *Extensions* for details.
`import`	Optional. If `true`, imports projects from manifest files in the given repository into the current manifest. See *Manifest Imports* for details.
`groups`	Optional, a list of groups the project belongs to. See *Project Groups* for details.
`submodules`	Optional. You can use this to make `west update` also update Git submodules defined by the project. See *Git Submodules in Projects* for details.
`userdata`	Optional. The value is an arbitrary YAML value. See *Repository user data*.

Defaults The `defaults` subsection can provide default values for project attributes. In particular, the default remote name and revision can be specified here. Another way to write the same manifest we have been describing so far using `defaults` is:

```
manifest:
  defaults:
    remote: remote1
    revision: v1.3
```

(continues on next page)

[1] In git, HEAD is a reference, whereas HEAD~<n> is a valid revision but not a reference. West fetches references, such as refs/heads/main or HEAD, and commits not available locally, but will not fetch commits if they are already available. HEAD~0 is resolved to a specific commit that is locally available, and therefore west will simply checkout the locally available commit, identified by HEAD~0.

(continued from previous page)

```
remotes:
  - name: remote1
    url-base: https://git.example.com/base1
  - name: remote2
    url-base: https://git.example.com/base2

projects:
  - name: proj1
    description: the first example project
    path: extra/project-1
    revision: master
  - name: proj2
    description: |
      A multi-line description of the second example
      project.
    repo-path: my-path
    remote: remote2
  - name: proj3
    url: https://github.com/user/project-three
    revision: abcde413a111
```

The available `defaults` keys and their usage are in the following table.

Table 4: defaults keys

Key	Description
`remote`	Optional. This will be used for a project's `remote` if it does not have a `url` or `remote` key set.
`revision`	Optional. This will be used for a project's `revision` if it does not have one set. If not given, the default is `master`.

Self The `self` subsection can be used to control the manifest repository itself.

As an example, let's consider this snippet from the zephyr repository's `west.yml`:

```
manifest:
  # ...
  self:
    path: zephyr
    west-commands: scripts/west-commands.yml
```

This ensures that the zephyr repository is cloned into path `zephyr`, though as explained above that would have happened anyway if cloning from the default manifest URL, `https://github.com/zephyrproject-rtos/zephyr`. Since the zephyr repository does contain extension commands, its `self` entry declares the location of the corresponding `west-commands.yml` relative to the repository root.

The available `self` keys and their usage are in the following table.

Table 5: self keys

Key	Description
path	Optional. The path `west init` should clone the manifest repository into, relative to the west workspace topdir. If not given, the basename of the path component in the manifest repository URL will be used by default. For example, if the URL is `https://git.example.com/project-repo`, the manifest repository would be cloned to the directory `project-repo`.
west-commands	Optional. This is analogous to the same key in a project sequence element.
import	Optional. This is also analogous to the `projects` key, but allows importing projects from other files in the manifest repository. See *Manifest Imports*.

Version The `version` subsection declares that the manifest file uses features which were introduced in some version of west. Attempts to load the manifest with older versions of west will fail with an error message that explains the minimum required version of west which is needed.

Here is an example:

```
manifest:
  # Marks that this file uses version 0.10 of the west manifest
  # file format.
  #
  # An attempt to load this manifest file with west v0.8.0 will
  # fail with an error message saying that west v0.10.0 or
  # later is required.
  version: "0.10"
```

The pykwalify schema `manifest-schema.yml` in the west source code repository is used to validate the manifest section.

Here is a table with the valid `version` values, along with information about the manifest file features that were introduced in that version.

version	New features
"0.7"	Initial support for the version feature. All manifest file features that are not otherwise mentioned in this table were introduced in west v0.7.0 or earlier.
"0.8"	Support for import: path-prefix: (*Option 3: Mapping*)
"0.9"	**Use of west v0.9.x is discouraged.** This schema version is provided to allow users to explicitly request compatibility with west *v0.9.0*. However, west *v0.10.0* and later have incompatible behavior for features that were introduced in west v0.9.0. You should ignore version "0.9" if possible.
"0.10"	Support for: • submodules: in projects: (*Git Submodules in Projects*) • manifest: group-filter:, and groups: in projects: (*Project Groups*) • The import: feature now supports allowlist: and blocklist:; these are respectively recommended as replacements for older names as part of a general Zephyr-wide inclusive language change. The older key names are still supported for backwards compatibility. (*Manifest Imports*, *Option 3: Mapping*)
"0.12"	Support for userdata: in projects: (*Repository user data*)
"0.13"	Support for self: userdata: (*Repository user data*)
"1.0"	Identical to "0.13", but available for use by users that do not wish to use a "0.x" version field.
"1.2"	Support for description: in projects: (*Projects*)

Note

Versions of west without any new features in the manifest file format do not change the list of valid version values. For example, version: "0.11" is **not** valid, because west v0.11.x did not introduce new manifest file format features.

Quoting the version value as shown above forces the YAML parser to treat it as a string. Without quotes, 0.10 in YAML is just the floating point value 0.1. You can omit the quotes if the value is the same when cast to string, but it's best to include them. Always use quotes if you're not sure.

If you do not include a version in your manifest, each new release of west assumes that it should try to load it using the features that were available in that release. This may result in error messages that are harder to understand if that version of west is too old to load the manifest.

Group-filter See *Project Groups*.

Active and Inactive Projects

Projects defined in the west manifest can be *inactive* or *active*. The difference is that an inactive project is generally ignored by west. For example, west update will not update inactive projects, and west list will not print information about them by default. As another example, any *Manifest Imports* in an inactive project will be ignored by west.

There are two ways to make a project inactive:

1. Using the manifest.project-filter configuration option. If a project is made active or inactive using this option, then the rules related to making a project inactive using its

`groups:` are ignored. That is, if a regular expression in `manifest.project-filter` applies to a project, the project's groups have no effect on whether it is active or inactive.

See the entry for this option in *Built-in Configuration Options* for details.

2. Otherwise, if a project has groups, and they are all disabled, then the project is inactive.

   See the following section for details.

Project Groups

You can use the `groups` and `group-filter` keys briefly described *above* to place projects into groups, and to enable or disable groups.

For example, this lets you run a `west forall` command only on the projects in the group by using `west forall --group`. This can also let you make projects inactive; see the previous section for more information on inactive projects.

The next section introduces project groups. The following section describes *Enabled and Disabled Project Groups*. There are some basic examples in *Project Group Examples*. Finally, *Group Filters and Imports* provides a simplified overview of how `group-filter` interacts with the *Manifest Imports* feature.

Groups Basics The `groups:` and `group-filter:` keys appear in the manifest like this:

```
manifest:
  projects:
    - name: some-project
      groups: ...
  group-filter: ...
```

The `groups` key's value is a list of group names. Group names are strings.

You can enable or disable project groups using `group-filter`. Projects whose groups are all disabled, and which are not otherwise made active by a `manifest.project-filter` configuration option, are inactive.

For example, in this manifest fragment:

```
manifest:
  projects:
    - name: project-1
      groups:
        - groupA
    - name: project-2
      groups:
        - groupB
        - groupC
    - name: project-3
```

The projects are in these groups:

- `project-1`: one group, named `groupA`
- `project-2`: two groups, named `groupB` and `groupC`
- `project-3`: no groups

Project group names must not contain commas (,), colons (:), or whitespace.

Group names must not begin with a dash (-) or the plus sign (+), but they may contain these characters elsewhere in their names. For example, `foo-bar` and `foo+bar` are valid groups, but `-foobar` and `+foobar` are not.

Group names are otherwise arbitrary strings. Group names are case sensitive.

As a restriction, no project may use both `import:` and `groups:`. (This is necessary to avoid some pathological edge cases.)

Enabled and Disabled Project Groups All project groups are enabled by default. You can enable or disable groups in both your manifest file and *Configuration*.

Within a manifest file, `manifest: group-filter:` is a YAML list of groups to enable and disable.

To enable a group, prefix its name with a plus sign (+). For example, `groupA` is enabled in this manifest fragment:

```
manifest:
  group-filter: [+groupA]
```

Although this is redundant for groups that are already enabled by default, it can be used to override settings in an imported manifest file. See *Group Filters and Imports* for more information.

To disable a group, prefix its name with a dash (-). For example, `groupA` and `groupB` are disabled in this manifest fragment:

```
manifest:
  group-filter: [-groupA,-groupB]
```

Note

Since `group-filter` is a YAML list, you could have written this fragment as follows:

```
manifest:
  group-filter:
    - -groupA
    - -groupB
```

However, this syntax is harder to read and therefore discouraged.

In addition to the manifest file, you can control which groups are enabled and disabled using the `manifest.group-filter` configuration option. This option is a comma-separated list of groups to enable and/or disable.

To enable a group, add its name to the list prefixed with `+`. To disable a group, add its name prefixed with `-`. For example, setting `manifest.group-filter` to `+groupA,-groupB` enables `groupA`, and disables `groupB`.

The value of the configuration option overrides any data in the manifest file. You can think of this as if the `manifest.group-filter` configuration option is appended to the `manifest: group-filter:` list from YAML, with "last entry wins" semantics.

Project Group Examples This section contains example situations involving project groups and active projects. The examples use both `manifest: group-filter:` YAML lists and `manifest.group-filter` configuration lists, to show how they work together.

Note that the `defaults` and `remotes` data in the following manifests isn't relevant except to make the examples complete and self-contained.

Note

In all of the examples that follow, the `manifest.project-filter` option is assumed to be unset.

Example 1: no disabled groups The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB
    - name: baz

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

No groups are disabled, because all groups are enabled by default. Therefore, all three projects (`foo`, `bar`, and `baz`) are active. Note that there is no way to make project `baz` inactive, since it has no groups.

Example 2: Disabling one group via manifest The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  group-filter: [-groupA]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

Since `groupA` is disabled, project `foo` is inactive. Project `bar` is active, because `groupB` is enabled.

Example 3: Disabling multiple groups via manifest The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
```

(continues on next page)

(continued from previous page)

```
      - groupB

  group-filter: [-groupA,-groupB]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

Both `foo` and `bar` are inactive, because all of their groups are disabled.

Example 4: Disabling a group via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `-groupA` (you can ensure this by running `west config manifest.group-filter -- -groupA`; the extra `--` is required so the argument parser does not treat `-groupA` as a command line option `-g` with value `roupA`).

Project `foo` is inactive because `groupA` has been disabled by the `manifest.group-filter` configuration option. Project `bar` is active because `groupB` is enabled.

Example 5: Overriding a disabled group via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
      groups:
        - groupA
        - groupB

  group-filter: [-groupA]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `+groupA` (you can ensure this by running `west config manifest.group-filter +groupA`).

In this case, `groupA` is enabled: the `manifest.group-filter` configuration option has higher precedence than the `manifest: group-filter: [-groupA]` content in the manifest file.

Therefore, projects `foo` and `bar` are both active.

Example 6: Overriding multiple disabled groups via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
      groups:
        - groupA
        - groupB

  group-filter: [-groupA,-groupB]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `+groupA,+groupB` (you can ensure this by running `west config manifest.group-filter "+groupA,+groupB"`).

In this case, both `groupA` and `groupB` are enabled, because the configuration value overrides the manifest file for both groups.

Therefore, projects `foo` and `bar` are both active.

Example 7: Disabling multiple groups via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
      groups:
        - groupA
        - groupB

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `-groupA,-groupB` (you can ensure this by running `west config manifest.group-filter -- "-groupA,-groupB"`).

In this case, both `groupA` and `groupB` are disabled.

Therefore, projects `foo` and `bar` are both inactive.

Group Filters and Imports This section provides a simplified description of how the `manifest: group-filter:` value behaves when combined with *Manifest Imports*. For complete details, see *Manifest Import Details*.

Warning

The below semantics apply to west v0.10.0 and later. West v0.9.x semantics are different, and combining `group-filter` with `import` in west v0.9.x is discouraged.

In short:

- if you only import one manifest, any groups it disables in its `group-filter` are also disabled in your manifest
- you can override this in your manifest file's `manifest: group-filter:` value, your workspace's `manifest.group-filter` configuration option, or both

Here are some examples.

Example 1: no overrides You are using this `parent/west.yml` manifest:

```
# parent/west.yml:
manifest:
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And `child/west.yml` contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

Only `child` and `project-2` are active in the resolved manifest.

The `unstable` group is disabled in `child/west.yml`, and that is not overridden in `parent/west.yml`. Therefore, the final `group-filter` for the resolved manifest is `[-unstable]`.

Since `project-1` and `project-3` are in the `unstable` group and are not in any other group, they are inactive.

Example 2: overriding an imported `group-filter` via manifest You are using this `parent/west.yml` manifest:

```
# parent/west.yml:
manifest:
  group-filter: [+unstable,-optional]
  projects:
```

(continues on next page)

(continued from previous page)

```
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And `child/west.yml` contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
      groups:
        - optional
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

Only the `child`, `project-1`, and `project-3` projects are active.

The `[-unstable]` group filter in `child/west.yml` is overridden in `parent/west.yml`, so the `unstable` group is enabled. Since `project-1` and `project-3` are in the `unstable` group, they are active.

The same `parent/west.yml` file disables the `optional` group, so `project-2` is inactive.

The final group filter specified by `parent/west.yml` is `[+unstable,-optional]`.

Example 3: overriding an imported `group-filter` via configuration You are using this `parent/west.yml` manifest:

```
# parent/west.yml:
manifest:
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And `child/west.yml` contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
      groups:
        - optional
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

If you run:

```
west config manifest.group-filter +unstable,-optional
```

Then only the `child`, `project-1`, and `project-3` projects are active.

The `-unstable` group filter in `child/west.yml` is overridden in the `manifest.group-filter` configuration option, so the `unstable` group is enabled. Since `project-1` and `project-3` are in the `unstable` group, they are active.

The same configuration option disables the `optional` group, so `project-2` is inactive.

The final group filter specified by `parent/west.yml` and the `manifest.group-filter` configuration option is `[+unstable,-optional]`.

Git Submodules in Projects

You can use the `submodules` keys briefly described *above* to force `west update` to also handle any Git submodules configured in project's git repository. The `submodules` key can appear inside `projects`, like this:

```
manifest:
  projects:
    - name: some-project
      submodules: ...
```

The `submodules` key can be a boolean or a list of mappings. We'll describe these in order.

Option 1: Boolean This is the easiest way to use `submodules`.

If `submodules` is `true` as a `projects` attribute, `west update` will recursively update the project's Git submodules whenever it updates the project itself. If it's `false` or missing, it has no effect.

For example, let's say you have a source code repository `foo`, which has some submodules, and you want `west update` to keep all of them in sync, along with another project named `bar` in the same workspace.

You can do that with this manifest file:

```
manifest:
  projects:
    - name: foo
      submodules: true
    - name: bar
```

Here, `west update` will initialize and update all submodules in `foo`. If `bar` has any submodules, they are ignored, because `bar` does not have a `submodules` value.

Option 2: List of mappings The `submodules` key may be a list of mappings, one list element for each desired submodule. Each submodule listed is updated recursively. You can still track and update unlisted submodules with `git` commands manually; present or not they will be completely ignored by `west`.

The `path` key must match exactly the path of one submodule relative to its parent west project, as shown in the output of `git submodule status`. The `name` key is optional and not used by west for now; it's not passed to `git submodule` commands either. The `name` key was briefly mandatory in west version 0.9.0, but was made optional in 0.9.1.

For example, let's say you have a source code repository `foo`, which has many submodules, and you want `west update` to keep some but not all of them in sync, along with another project named `bar` in the same workspace.

You can do that with this manifest file:

```
manifest:
  projects:
    - name: foo
      submodules:
        - path: path/to/foo-first-sub
        - name: foo-second-sub
          path: path/to/foo-second-sub
    - name: bar
```

Here, `west update` will recursively initialize and update just the submodules in `foo` with paths `path/to/foo-first-sub` and `path/to/foo-second-sub`. Any submodules in `bar` are still ignored.

Repository user data

West versions v0.12 and later support an optional `userdata` key in projects.

West versions v0.13 and later supports this key in the `manifest: self:` section.

It is meant for consumption by programs that require user-specific project metadata. Beyond parsing it as YAML, west itself ignores the value completely.

The key's value is arbitrary YAML. West parses the value and makes it accessible to programs using west-apis as the `userdata` attribute of the corresponding `west.manifest.Project` object.

Example manifest fragment:

```
manifest:
  projects:
    - name: foo
    - name: bar
      userdata: a-string
    - name: baz
      userdata:
        key: value
  self:
    userdata: blub
```

Example Python usage:

```
manifest = west.manifest.Manifest.from_file()

foo, bar, baz = manifest.get_projects(['foo', 'bar', 'baz'])

foo.userdata # None
bar.userdata # 'a-string'
baz.userdata # {'key': 'value'}
manifest.userdata # 'blub'
```

Manifest Imports

You can use the `import` key briefly described above to include projects from other manifest files in your `west.yml`. This key can be either a `project` or `self` section attribute:

```
manifest:
  projects:
    - name: some-project
      import: ...
  self:
    import: ...
```

You can use a "self: import:" to load additional files from the repository containing your `west.yml`. You can use a "project: ... import:" to load additional files defined in that project's Git history.

West resolves the final manifest from individual manifest files in this order:

1. imported files in `self`
2. your `west.yml` file
3. imported files in `projects`

During resolution, west ignores projects which have already been defined in other files. For example, a project named `foo` in your `west.yml` makes west ignore other projects named `foo` imported from your `projects` list.

The `import` key can be a boolean, path, mapping, or sequence. We'll describe these in order, using examples:

- ***Boolean***
  - *Example 1.1: Downstream of a Zephyr release*
  - *Example 1.2: "Rolling release" Zephyr downstream*
  - *Example 1.3: Downstream of a Zephyr release, with module fork*
- ***Relative path***
  - *Example 2.1: Downstream of a Zephyr release with explicit path*
  - *Example 2.2: Downstream with directory of manifest files*
  - *Example 2.3: Continuous Integration overrides*
- ***Mapping with additional configuration***
  - *Example 3.1: Downstream with name allowlist*
  - *Example 3.2: Downstream with path allowlist*
  - *Example 3.3: Downstream with path blocklist*
  - *Example 3.4: Import into a subdirectory*
- ***Sequence of paths and mappings***
  - *Example 4.1: Downstream with sequence of manifest files*
  - *Example 4.2: Import order illustration*

A more *formal description* of how this works is last, after the examples.

Troubleshooting Note If you're using this feature and find west's behavior confusing, try *resolving your manifest* to see the final results after imports are done.

Option 1: Boolean This is the easiest way to use `import`.

If `import` is `true` as a `projects` attribute, west imports projects from the `west.yml` file in that project's root directory. If it's `false` or missing, it has no effect. For example, this manifest would import `west.yml` from the `p1` git repository at revision `v1.0`:

```
manifest:
  # ...
  projects:
    - name: p1
      revision: v1.0
      import: true    # Import west.yml from p1's v1.0 git tag
    - name: p2
```

(continues on next page)

(continued from previous page)

```
      import: false   # Nothing is imported from p2.
    - name: p3        # Nothing is imported from p3 either.
```

It's an error to set `import` to either `true` or `false` inside `self`, like this:

```
manifest:
  # ...
  self:
    import: true  # Error
```

Example 1.1: Downstream of a Zephyr release You have a source code repository you want to use with Zephyr v1.14.1 LTS. You want to maintain the whole thing using west. You don't want to modify any of the mainline repositories.

In other words, the west workspace you want looks like this:

```
my-downstream/
├── .west/                    # west directory
├── zephyr/                   # mainline zephyr repository
│   └── west.yml              # the v1.14.1 version of this file is imported
├── modules/                  # modules from mainline zephyr
│   ├── hal/
│   └── [...other directories..]
├── [ ... other projects ...]  # other mainline repositories
└── my-repo/                  # your downstream repository
    ├── west.yml              # main manifest importing zephyr/west.yml v1.14.1
    └── [...other files..]
```

You can do this with the following `my-repo/west.yml`:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v1.14.1
      import: true
```

You can then create the workspace on your computer like this, assuming `my-repo` is hosted at `https://git.example.com/my-repo`:

```
west init -m https://git.example.com/my-repo my-downstream
cd my-downstream
west update
```

After `west init`, `my-downstream/my-repo` will be cloned.

After `west update`, all of the projects defined in the `zephyr` repository's `west.yml` at revision `v1.14.1` will be cloned into `my-downstream` as well.

You can add and commit any code to `my-repo` you please at this point, including your own Zephyr applications, drivers, etc. See *Application Development*.

Example 1.2: "Rolling release" Zephyr downstream This is similar to *Example 1.1: Downstream of a Zephyr release*, except we'll use `revision: main` for the zephyr repository:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
```

You can create the workspace in the same way:

```
west init -m https://git.example.com/my-repo my-downstream
cd my-downstream
west update
```

This time, whenever you run `west update`, the special *manifest-rev* branch in the `zephyr` repository will be updated to point at a newly fetched `main` branch tip from the URL https://github.com/zephyrproject-rtos/zephyr.

The contents of `zephyr/west.yml` at the new `manifest-rev` will then be used to import projects from Zephyr. This lets you stay up to date with the latest changes in the Zephyr project. The cost is that running `west update` will not produce reproducible results, since the remote `main` branch can change every time you run it.

It's also important to understand that west **ignores your working tree's** `zephyr/west.yml` entirely when resolving imports. West always uses the contents of imported manifests as they were committed to the latest `manifest-rev` when importing from a project.

You can only import manifest from the file system if they are in your manifest repository's working tree. See *Example 2.2: Downstream with directory of manifest files* for an example.

Example 1.3: Downstream of a Zephyr release, with module fork This manifest is similar to the one in *Example 1.1: Downstream of a Zephyr release*, except it:

- is a downstream of Zephyr 2.0
- includes a downstream fork of the `modules/hal/nordic` *module* which was included in that release

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
    - name: my-remote
      url-base: https://git.example.com
  projects:
    - name: hal_nordic         # higher precedence
      remote: my-remote
      revision: my-sha
      path: modules/hal/nordic
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.0.0
      import: true             # imported projects have lower precedence

# subset of zephyr/west.yml contents at v2.0.0:
manifest:
  defaults:
    remote: zephyrproject-rtos
```

(continues on next page)

(continued from previous page)

```
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
  # ...
  - name: hal_nordic           # lower precedence, values ignored
    path: modules/hal/nordic
    revision: another-sha
```

With this manifest file, the project named `hal_nordic`:

- is cloned from `https://git.example.com/hal_nordic` instead of `https://github.com/zephyrproject-rtos/hal_nordic`.
- is updated to commit `my-sha` by `west update`, instead of the mainline commit `another-sha`

In other words, when your top-level manifest defines a project, like `hal_nordic`, west will ignore any other definition it finds later on while resolving imports.

This does mean you have to copy the `path: modules/hal/nordic` value into `my-repo/west.yml` when defining `hal_nordic` there. The value from `zephyr/west.yml` is ignored entirely. See *Resolving Manifests* for troubleshooting advice if this gets confusing in practice.

When you run `west update`, west will:

- update zephyr's `manifest-rev` to point at the `v2.0.0` tag
- import `zephyr/west.yml` at that `manifest-rev`
- locally check out the `v2.0.0` revisions for all zephyr projects except `hal_nordic`
- update `hal_nordic` to `my-sha` instead of `another-sha`

Option 2: Relative path The `import` value can also be a relative path to a manifest file or a directory containing manifest files. The path is relative to the root directory of the `projects` or `self` repository the `import` key appears in.

Here is an example:

```
manifest:
  projects:
    - name: project-1
      revision: v1.0
      import: west.yml
    - name: project-2
      revision: main
      import: p2-manifests
  self:
    import: submanifests
```

This will import the following:

- the contents of `project-1/west.yml` at `manifest-rev`, which points at tag `v1.0` after running `west update`
- any YAML files in the directory tree `project-2/p2-manifests` at the latest commit in the `main` branch, as fetched by `west update`, sorted by file name
- YAML files in `submanifests` in your manifest repository, as they appear on your file system, sorted by file name

Notice how `projects` imports get data from Git using `manifest-rev`, while `self` imports get data from your file system. This is because as usual, west leaves version control for your manifest repository up to you.

Example 2.1: Downstream of a Zephyr release with explicit path This is an explicit way to write an equivalent manifest to the one in *Example 1.1: Downstream of a Zephyr release*.

```
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v1.14.1
      import: west.yml
```

The setting `import: west.yml` means to use the file `west.yml` inside the `zephyr` project. This example is contrived, but shows the idea.

This can be useful in practice when the name of the manifest file you want to import is not `west.yml`.

Example 2.2: Downstream with directory of manifest files Your Zephyr downstream has a lot of additional repositories. So many, in fact, that you want to split them up into multiple manifest files, but keep track of them all in a single manifest repository, like this:

```
my-repo/
├── submanifests
│   ├── 01-libraries.yml
│   ├── 02-vendor-hals.yml
│   └── 03-applications.yml
└── west.yml
```

You want to add all the files in `my-repo/submanifests` to the main manifest file, `my-repo/west.yml`, in addition to projects in `zephyr/west.yml`. You want to track the latest development code in the Zephyr repository's `main` branch instead of using a fixed revision.

Here's how:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
  self:
    import: submanifests
```

Manifest files are imported in this order during resolution:

1. `my-repo/submanifests/01-libraries.yml`
2. `my-repo/submanifests/02-vendor-hals.yml`
3. `my-repo/submanifests/03-applications.yml`
4. `my-repo/west.yml`
5. `zephyr/west.yml`

Note

The `.yml` file names are prefixed with numbers in this example to make sure they are imported in the specified order.

You can pick arbitrary names. West sorts files in a directory by name before importing.

Notice how the manifests in `submanifests` are imported *before* `my-repo/west.yml` and `zephyr/west.yml`. In general, an `import` in the `self` section is processed before the manifest files in `projects` and the main manifest file.

This means projects defined in `my-repo/submanifests` take highest precedence. For example, if `01-libraries.yml` defines `hal_nordic`, the project by the same name in `zephyr/west.yml` is simply ignored. As usual, see *Resolving Manifests* for troubleshooting advice.

This may seem strange, but it allows you to redefine projects "after the fact", as we'll see in the next example.

Example 2.3: Continuous Integration overrides Your continuous integration system needs to fetch and test multiple repositories in your west workspace from a developer's forks instead of your mainline development trees, to see if the changes all work well together.

Starting with *Example 2.2: Downstream with directory of manifest files*, the CI scripts add a file `00-ci.yml` in `my-repo/submanifests`, with these contents:

```
# my-repo/submanifests/00-ci.yml:
manifest:
  projects:
    - name: a-vendor-hal
      url: https://github.com/a-developer/hal
      revision: a-pull-request-branch
    - name: an-application
      url: https://github.com/a-developer/application
      revision: another-pull-request-branch
```

The CI scripts run `west update` after generating this file in `my-repo/submanifests`. The projects defined in `00-ci.yml` have higher precedence than other definitions in `my-repo/submanifests`, because the name `00-ci.yml` comes before the other file names.

Thus, `west update` always checks out the developer's branches in the projects named `a-vendor-hal` and `an-application`, even if those same projects are also defined elsewhere.

Option 3: Mapping The `import` key can also contain a mapping with the following keys:

- `file`: Optional. The name of the manifest file or directory to import. This defaults to `west.yml` if not present.
- `name-allowlist`: Optional. If present, a name or sequence of project names to include.
- `path-allowlist`: Optional. If present, a path or sequence of project paths to match against. This is a shell-style globbing pattern, currently implemented with pathlib. Note that this means case sensitivity is platform specific.
- `name-blocklist`: Optional. Like `name-allowlist`, but contains project names to exclude rather than include.
- `path-blocklist`: Optional. Like `path-allowlist`, but contains project paths to exclude rather than include.

- `path-prefix`: Optional (new in v0.8.0). If given, this will be prepended to the project's path in the workspace, as well as the paths of any imported projects. This can be used to place these projects in a subdirectory of the workspace.

Allowlists override blocklists if both are given. For example, if a project is blocked by path, then allowed by name, it will still be imported.

Example 3.1: Downstream with name allowlist Here is a pair of manifest files, representing a mainline and a downstream. The downstream doesn't want to use all the mainline projects, however. We'll assume the mainline `west.yml` is hosted at `https://git.example.com/mainline/manifest`.

```
# mainline west.yml:
manifest:
  projects:
    - name: mainline-app                # included
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib
      path: libraries/lib
      url: https://git.example.com/mainline/lib
    - name: lib2                        # included
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        name-allowlist:
          - mainline-app
          - lib2
    - name: downstream-app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

An equivalent manifest in a single file would be:

```
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
    - name: downstream-app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
    - name: mainline-app                # imported
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib2                        # imported
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2
```

If an allowlist had not been used, the `lib` project from the mainline manifest would have been imported.

Example 3.2: Downstream with path allowlist Here is an example showing how to allowlist mainline's libraries only, using `path-allowlist`.

```
# mainline west.yml:
manifest:
  projects:
    - name: app
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib
      path: libraries/lib                  # included
      url: https://git.example.com/mainline/lib
    - name: lib2
      path: libraries/lib2                 # included
      url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        path-allowlist: libraries/*
    - name: app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

An equivalent manifest in a single file would be:

```
manifest:
  projects:
    - name: lib                          # imported
      path: libraries/lib
      url: https://git.example.com/mainline/lib
    - name: lib2                         # imported
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2
    - name: mainline
      url: https://git.example.com/mainline/manifest
    - name: app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

Example 3.3: Downstream with path blocklist Here's an example showing how to block all vendor HALs from mainline by common path prefix in the workspace, add your own version for the chip you're targeting, and keep everything else.

```
# mainline west.yml:
manifest:
  defaults:
    remote: mainline
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app
    - name: lib
```

(continues on next page)

(continued from previous page)

```
      path: libraries/lib
    - name: lib2
      path: libraries/lib2
    - name: hal_foo
      path: modules/hals/foo     # excluded
    - name: hal_bar
      path: modules/hals/bar     # excluded
    - name: hal_baz
      path: modules/hals/baz     # excluded

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        path-blocklist: modules/hals/*
    - name: hal_foo
      path: modules/hals/foo
      url: https://git.example.com/downstream/hal_foo
```

An equivalent manifest in a single file would be:

```
manifest:
  defaults:
    remote: mainline
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app                  # imported
    - name: lib                  # imported
      path: libraries/lib
    - name: lib2                 # imported
      path: libraries/lib2
    - name: mainline
      repo-path: https://git.example.com/mainline/manifest
    - name: hal_foo
      path: modules/hals/foo
      url: https://git.example.com/downstream/hal_foo
```

Example 3.4: Import into a subdirectory You want to import a manifest and its projects, placing everything into a subdirectory of your *west workspace*.

For example, suppose you want to import this manifest from project `foo`, adding this project and its projects `bar` and `baz` to your workspace:

```
# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
    - name: example
      url-base: https://git.example.com
  projects:
    - name: bar
    - name: baz
```

Instead of importing these into the top level workspace, you want to place all three project repositories in an `external-code` subdirectory, like this:

```
workspace/
└── external-code/
    ├── foo/
    ├── bar/
    └── baz/
```

You can do this using this manifest:

```yaml
manifest:
  projects:
    - name: foo
      url: https://git.example.com/foo
      import:
        path-prefix: external-code
```

An equivalent manifest in a single file would be:

```yaml
# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
    - name: example
      url-base: https://git.example.com
  projects:
    - name: foo
      path: external-code/foo
    - name: bar
      path: external-code/bar
    - name: baz
      path: external-code/baz
```

Option 4: Sequence The `import` key can also contain a sequence of files, directories, and mappings.

Example 4.1: Downstream with sequence of manifest files This example manifest is equivalent to the manifest in *Example 2.2: Downstream with directory of manifest files*, with a sequence of explicitly named files.

```yaml
# my-repo/west.yml:
manifest:
  projects:
    - name: zephyr
      url: https://github.com/zephyrproject-rtos/zephyr
      import: west.yml
  self:
    import:
      - submanifests/01-libraries.yml
      - submanifests/02-vendor-hals.yml
      - submanifests/03-applications.yml
```

Example 4.2: Import order illustration This more complicated example shows the order that west imports manifest files:

```yaml
# my-repo/west.yml
manifest:
  # ...
```

(continues on next page)

(continued from previous page)

```
  projects:
    - name: my-library
    - name: my-app
    - name: zephyr
      import: true
    - name: another-manifest-repo
      import: submanifests
  self:
    import:
      - submanifests/libraries.yml
      - submanifests/vendor-hals.yml
      - submanifests/applications.yml
  defaults:
    remote: my-remote
```

For this example, west resolves imports in this order:

1. the listed files in `my-repo/submanifests` are first, in the order they occur (e.g. `libraries.yml` comes before `applications.yml`, since this is a sequence of files), since the `self: import:` is always imported first
2. `my-repo/west.yml` is next (with projects `my-library` etc. as long as they weren't already defined somewhere in `submanifests`)
3. `zephyr/west.yml` is after that, since that's the first `import` key in the `projects` list in `my-repo/west.yml`
4. files in `another-manifest-repo/submanifests` are last (sorted by file name), since that's the final project `import`

Manifest Import Details This section describes how west resolves a manifest file that uses `import` a bit more formally.

Overview The `import` key can appear in a west manifest's `projects` and `self` sections. The general case looks like this:

```
# Top-level manifest file.
manifest:
  projects:
    - name: foo
      import:
        ... # import-1
    - name: bar
      import:
        ... # import-2
    # ...
    - name: baz
      import:
        ... # import-N
  self:
    import:
      ... # self-import
```

Import keys are optional. If any of `import-1`, `...`, `import-N` are missing, west will not import additional manifest data from that project. If `self-import` is missing, no additional files in the manifest repository (beyond the top-level file) are imported.

The ultimate outcomes of resolving manifest imports are:

- a `projects` list, which is produced by combining the `projects` defined in the top-level file with those defined in imported files

- a set of extension commands, which are drawn from the `west-commands` keys in the top-level file and any imported files
- a `group-filter` list, which is produced by combining the top-level and any imported filters

Importing is done in this order:

1. Manifests from `self-import` are imported first.
2. The top-level manifest file's definitions are handled next.
3. Manifests from `import-1`, ..., `import-N`, are imported in that order.

When an individual `import` key refers to multiple manifest files, they are processed in this order:

- If the value is a relative path naming a directory (or a map whose `file` is a directory), the manifest files it contains are processed in lexicographic order – i.e., sorted by file name.
- If the value is a sequence, its elements are recursively imported in the order they appear.

This process recurses if necessary. E.g., if `import-1` produces a manifest file that contains an `import` key, it is resolved recursively using the same rules before its contents are processed further.

The following sections describe these outcomes.

Projects This section describes how the final `projects` list is created.

Projects are identified by name. If the same name occurs in multiple manifests, the first definition is used, and subsequent definitions are ignored. For example, if `import-1` contains a project named `bar`, that is ignored, because the top-level `west.yml` has already defined a project by that name.

The contents of files named by `import-1` through `import-N` are imported from Git at the latest `manifest-rev` revisions in their projects. These revisions can be updated to the values `rev-1` through `rev-N` by running `west update`. If any `manifest-rev` reference is missing or out of date, `west update` also fetches project data from the remote fetch URL and updates the reference.

Also note that all imported manifests, from the root manifest to the repository which defines a project `P`, must be up to date in order for west to update `P` itself. For example, this means `west update P` would update `manifest-rev` in the `baz` project if `baz/west.yml` defines `P`, as well as updating the `manifest-rev` branch in the local git clone of `P`. Confusingly, updating `baz` may result in the removal of `P` from `baz/west.yml`, which "should" cause `west update P` to fail with an unrecognized project!

For this reason, it's not possible to run `west update P` if `P` is defined in an imported manifest; you must update this project along with all the others with a plain `west update`.

By default, west won't fetch any project data over the network if a project's revision is a SHA or tag which is already available locally, so updating the extra projects shouldn't take too much time unless it's really needed. See the documentation for the *update.fetch* configuration option for more information.

Extensions All extension commands defined using `west-commands` keys discovered while handling imports are available in the resolved manifest.

If an imported manifest file has a `west-commands:` definition in its `self:` section, the extension commands defined there are added to the set of available extensions at the time the manifest is imported. They will thus take precedence over any extension commands with the same names added later on.

Group filters The resolved manifest has a `group-filter` value which is the result of concatenating the `group-filter` values in the top-level manifest and any imported manifests.

Manifest files which appear earlier in the import order have higher precedence and are therefore concatenated later into the final `group-filter`.

In other words, let:

- the submanifest resolved from `self-import` have group filter `self-filter`
- the top-level manifest file have group filter `top-filter`
- the submanifests resolved from `import-1` through `import-N` have group filters `filter-1` through `filter-N` respectively

The final resolved `group-filter` value is then `filterN + ... + filter-2 + filter-1 + top-filter + self-filter`, where `+` here refers to list concatenation.

Important

The order that filters appear in the above list matters.

The last filter element in the final concatenated list "wins" and determines if the group is enabled or disabled.

For example, in `[-foo] + [+foo]`, group `foo` is *enabled*. However, in `[+foo] + [-foo]`, group `foo` is *disabled*.

For simplicity, west and this documentation may elide concatenated group filter elements which are redundant using these rules. For example, `[+foo] + [-foo]` could be written more simply as `[-foo]`, for the reasons given above. As another example, `[-foo] + [+foo]` could be written as the empty list `[]`, since all groups are enabled by default.

Manifest Command

The `west manifest` command can be used to manipulate manifest files. It takes an action, and action-specific arguments.

The following sections describe each action and provides a basic signature for simple uses. Run `west manifest --help` for full details on all options.

Resolving Manifests The `--resolve` action outputs a single manifest file equivalent to your current manifest and all its *imported manifests*:

```
west manifest --resolve [-o outfile]
```

The main use for this action is to see the "final" manifest contents after performing any `imports`.

To print detailed information about each imported manifest file and how projects are handled during manifest resolution, set the maximum verbosity level using `-v`:

```
west -v manifest --resolve
```

Freezing Manifests The `--freeze` action outputs a frozen manifest:

```
west manifest --freeze [-o outfile]
```

A "frozen" manifest is a manifest file where every project's revision is a SHA. You can use `--freeze` to produce a frozen manifest that's equivalent to your current manifest file. The `-o` option specifies an output file; if not given, standard output is used.

Validating Manifests The `--validate` action either succeeds if the current manifest file is valid, or fails with an error:

```
west manifest --validate
```

The error message can help diagnose errors.

Here, "invalid" means that the syntax of the manifest file doesn't follow the rules documented on this page.

If your manifest is valid but it's not working the way you want it to, turning up the verbosity with `-v` is a good way to get detailed information about what decisions west made about your manifest, and why:

```
west -v manifest --validate
```

Get the manifest path The `--path` action prints the path to the top level manifest file:

```
west manifest --path
```

The output is something like `/path/to/workspace/west.yml`. The path format depends on your operating system.

2.11.8 Configuration

This page documents west's configuration file system, the `west config` command, and configuration options used by built-in commands. For API documentation on the `west.configuration` module, see west-apis-configuration.

West Configuration Files

West's configuration file syntax is INI-like; here is an example file:

```
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

Above, the `manifest` section has option `path` set to `zephyr`. Another way to say the same thing is that `manifest.path` is `zephyr` in this file.

There are three types of configuration file:

1. **System**: Settings in this file affect west's behavior for every user logged in to the computer. Its location depends on the platform:
   - Linux: `/etc/westconfig`
   - macOS: `/usr/local/etc/westconfig`
   - Windows: `%PROGRAMDATA%\west\config`
2. **Global** (per user): Settings in this file affect how west behaves when run by a particular user on the computer.
   - All platforms: the default is `.westconfig` in the user's home directory.
   - Linux note: if the environment variable `XDG_CONFIG_HOME` is set, then `$XDG_CONFIG_HOME/west/config` is used.

- Windows note: the following environment variables are tested to find the home directory: `%HOME%`, then `%USERPROFILE%`, then a combination of `%HOMEDRIVE%` and `%HOMEPATH%`.

3. **Local**: Settings in this file affect west's behavior for the current *west workspace*. The file is `.west/config`, relative to the workspace's root directory.

A setting in a file which appears lower down on this list overrides an earlier setting. For example, if `color.ui` is `true` in the system's configuration file, but `false` in the workspace's, then the final value is `false`. Similarly, settings in the user configuration file override system settings, and so on.

west config

The built-in `config` command can be used to get and set configuration values. You can pass `west config` the options `--system`, `--global`, or `--local` to specify which configuration file to use. Only one of these can be used at a time. If none is given, then writes default to `--local`, and reads show the final value after applying overrides.

Some examples for common uses follow; run `west config -h` for detailed help, and see *Built-in Configuration Options* for more details on built-in options.

To set `manifest.path` to `some-other-manifest`:

```
west config manifest.path some-other-manifest
```

Doing the above means that commands like `west update` will look for the *west manifest* inside the `some-other-manifest` directory (relative to the workspace root directory) instead of the directory given to `west init`, so be careful!

To read `zephyr.base`, the value which will be used as `ZEPHYR_BASE` if it is unset in the calling environment (also relative to the workspace root):

```
west config zephyr.base
```

You can switch to another zephyr repository without changing `manifest.path` – and thus the behavior of commands like `west update` – using:

```
west config zephyr.base some-other-zephyr
```

This can be useful if you use commands like `git worktree` to create your own zephyr directories, and want commands like `west build` to use them instead of the zephyr repository specified in the manifest. (You can go back to using the directory in the upstream manifest by running `west config zephyr.base zephyr`.)

To set `color.ui` to `false` in the global (user-wide) configuration file, so that west will no longer print colored output for that user when run in any workspace:

```
west config --global color.ui false
```

To undo the above change:

```
west config --global color.ui true
```

Built-in Configuration Options

The following table documents configuration options supported by west's built-in commands. Configuration options supported by Zephyr's extension commands are documented in the pages for those commands.

Option	Description
`color.ui`	Boolean. If `true` (the default), then west output is colorized when stdout is a terminal.
`commands.allow_extensions`	Boolean, default `true`, disables *Extensions* if `false`
`grep.color`	String, default empty. Set this to `never` to disable `west grep` color output. If set, `west grep` passes the value to the grep tool's `--color` option.
`grep.tool`	String, one of `"git-grep"` (default), `"ripgrep"`, or `"grep"`. The grep tool that `west grep` should use.
`grep.<TOOL>-args`	String, default empty. The `<TOOL>` part is a pattern that can be any `grep.tool` value, so `grep.ripgrep-args` is an example configuration option. If set, arguments that `west grep` should pass to the corresponding grep tool. Run `west help grep` for details.
`grep.<TOOL>-path`	String, default empty. The `<TOOL>` part is a pattern that can be any `grep.tool` value, so `grep.ripgrep-path` is an example configuration option. The path to the corresponding tool that `west grep` should use instead of searching for the command. Run `west help grep` for details.
`manifest.file`	String, default `west.yml`. Relative path from the manifest repository root directory to the manifest file used by `west init` and other commands which parse the manifest.
`manifest.group-filter`	String, default empty. A comma-separated list of project groups to enable and disable within the workspace. Prefix enabled groups with `+` and disabled groups with `-`. For example, the value `"+foo,-bar"` enables group `foo` and disables `bar`. See *Project Groups*.
`manifest.path`	String, relative path from the *west workspace* root directory to the manifest repository used by `west update` and other commands which parse the manifest. Set locally by `west init`.

`manifest.project-filter`	Comma-separated list of strings.
	The option's value is a comma-separated list of regular expressions, each prefixed with `+` or `-`, like this:
	`+re1,-re2,-re3`
	Project names are matched against each regular expression (`re1`, `re2`, `re3`, ...) in the list, in order. If the entire project name matches the regular expression, that element of the list either deactivates or activates the project. The project is deactivated if the element begins with `-`. The project is activated if the element begins with `+`. (Project names cannot contain `,` if this option is used, so the regular expressions do not need to contain a literal `,` character.)
	If a project's name matches multiple regular expressions in the list, the result from the last regular expression is used. For example, if `manifest.project-filter` is:
	`-hal_.*,+hal_foo`
	Then a project named `hal_bar` is inactive, but a project named `hal_foo` is active.
	If a project is made inactive or active by a list element, the project is active or not regardless of whether any or all of its groups are disabled. (This is currently the only way to make a project that has no groups inactive.)
	Otherwise, i.e. if a project does not match any regular expressions in the list, it is active or inactive according to the usual rules related to its groups (see *Project Group Examples* for examples in that case).
	Within an element of a `manifest.project-filter` list, leading and trailing whitespace are ignored. That means these example values are equivalent:
	`+foo,-bar`
	`+foo , -bar`
	Any empty elements are ignored. That means these example values are equivalent:
	`+foo,,-bar`
	`+foo,-bar`

`update.fetch`	String, one of `"smart"` (the default behavior starting in v0.6.1) or `"al-`

2.11.9 Extensions

West is "pluggable": you can add your own commands to west without editing its source code. These are called **west extension commands**, or just "extensions" for short. Extensions show up in the `west --help` output in a special section for the project which defines them. This page provides general information on west extension commands, and has a tutorial for writing your own.

Some commands you can run when using west with Zephyr, like the ones used to *build, flash, and debug* and the *ones described here* , are extensions. That's why help for them shows up like this in `west --help`:

```
commands from project at "zephyr":
  completion:           display shell completion scripts
  boards:               display information about supported boards
  build:                compile a Zephyr application
  sign:                 sign a Zephyr binary for bootloader chain-loading
  flash:                flash and run a binary on a board
  debug:                flash and interactively debug a Zephyr application
  debugserver:          connect to board and launch a debug server
  attach:               interactively debug a board
```

See `zephyr/scripts/west-commands.yml` and the `zephyr/scripts/west_commands` directory for the implementation details.

Disabling Extension Commands

To disable support for extension commands, set the `commands.allow_extensions` *configuration* option to `false`. To set this globally for whenever you run west, use:

```
west config --global commands.allow_extensions false
```

If you want to, you can then re-enable them in a particular *west workspace* with:

```
west config --local commands.allow_extensions true
```

Note that the files containing extension commands are not imported by west unless the commands are explicitly run. See below for details.

Adding a West Extension

There are three steps to adding your own extension:

1. Write the code implementing the command.
2. Add information about it to a `west-commands.yml` file.
3. Make sure the `west-commands.yml` file is referenced in the *west manifest*.

Note that west ignores extension commands whose names are the same as a built-in command.

Step 1: Implement Your Command Create a Python file to contain your command implementation (see the "Meta > Requires" information on the west PyPI page for details on the currently supported versions of Python). You can put it in anywhere in any project tracked by your *west manifest*, or the manifest repository itself. This file must contain a subclass of the `west.commands.WestCommand` class; this class will be instantiated and used when your extension is run.

Here is a basic skeleton you can use to get started. It contains a subclass of `WestCommand`, with implementations for all the abstract methods. For more details on the west APIs you can use, see west-apis.

```
'''my_west_extension.py

Basic example of a west extension.'''

from textwrap import dedent            # just for nicer code indentation

from west.commands import WestCommand  # your extension must subclass this
from west import log                   # use this for user output

class MyCommand(WestCommand):

    def __init__(self):
        super().__init__(
            'my-command-name',  # gets stored as self.name
            'one-line help for what my-command-name does',  # self.help
            # self.description:
            dedent('''
            A multi-line description of my-command.

            You can split this up into multiple paragraphs and they'll get
            reflowed for you. You can also pass
            formatter_class=argparse.RawDescriptionHelpFormatter when calling
            parser_adder.add_parser() below if you want to keep your line
            endings.'''))

    def do_add_parser(self, parser_adder):
        # This is a bit of boilerplate, which allows you full control over the
        # type of argparse handling you want. The "parser_adder" argument is
        # the return value of an argparse.ArgumentParser.add_subparsers() call.
        parser = parser_adder.add_parser(self.name,
                                         help=self.help,
                                         description=self.description)

        # Add some example options using the standard argparse module API.
        parser.add_argument('-o', '--optional', help='an optional argument')
        parser.add_argument('required', help='a required argument')

        return parser           # gets stored as self.parser

    def do_run(self, args, unknown_args):
        # This gets called when the user runs the command, e.g.:
        #
        #   $ west my-command-name -o FOO BAR
        #   --optional is FOO
        #   required is BAR
        log.inf('--optional is', args.optional)
        log.inf('required is', args.required)
```

You can ignore the second argument to `do_run()` (`unknown_args` above), as `WestCommand` will reject unknown arguments by default. If you want to be passed a list of unknown arguments instead, add `accepts_unknown_args=True` to the `super().__init__()` arguments.

Step 2: Add or Update Your `west-commands.yml` You now need to add a `west-commands.yml` file to your project which describes your extension to west.

Here is an example for the above class definition, assuming it's in `my_west_extension.py` at the project root directory:

```
west-commands:
  - file: my_west_extension.py
    commands:
```

(continues on next page)

(continued from previous page)

```
    - name: my-command-name
      class: MyCommand
      help: one-line help for what my-command-name does
```

The top level of this YAML file is a map with a `west-commands` key. The key's value is a sequence of "command descriptors". Each command descriptor gives the location of a file implementing west extensions, along with the names of those extensions, and optionally the names of the classes which define them (if not given, the `class` value defaults to the same thing as `name`).

Some information in this file is redundant with definitions in the Python code. This is because west won't import `my_west_extension.py` until the user runs `west my-command-name`, since:

- It allows users to run `west update` with a manifest from an untrusted source, then use other west commands without your code being imported along the way. Since importing a Python module is shell-equivalent, this provides some peace of mind.
- It's a small optimization, since your code will only be imported if it is needed.

So, unless your command is explicitly run, west will just load the `west-commands.yml` file to get the basic information it needs to display information about your extension to the user in `west --help` output, etc.

If you have multiple extensions, or want to split your extensions across multiple files, your `west-commands.yml` will look something like this:

```
west-commands:
  - file: my_west_extension.py
    commands:
      - name: my-command-name
        class: MyCommand
        help: one-line help for what my-command-name does
  - file: another_file.py
    commands:
      - name: command2
        help: another cool west extension
      - name: a-third-command
        class: ThirdCommand
        help: a third command in the same file as command2
```

Above:

- `my_west_extension.py` defines extension `my-command-name` with class `MyCommand`
- `another_file.py` defines two extensions:
  1. `command2` with class `command2`
  2. `a-third-command` with class `ThirdCommand`

See the file `west-commands-schema.yml` in the west repository for a schema describing the contents of a `west-commands.yml`.

Step 3: Update Your Manifest Finally, you need to specify the location of the `west-commands.yml` you just edited in your west manifest. If your extension is in a project, add it like this:

```
manifest:
   # [... other contents ...]

   projects:
     - name: your-project
       west-commands: path/to/west-commands.yml
     # [... other projects ...]
```

Where `path/to/west-commands.yml` is relative to the root of the project. Note that the name `west-commands.yml`, while encouraged, is just a convention; you can name the file something else if you need to.

Alternatively, if your extension is in the manifest repository, just do the same thing in the manifest's `self` section, like this:

```
manifest:
  # [... other contents ...]

  self:
    west-commands: path/to/west-commands.yml
```

That's it; you can now run `west my-command-name`. Your command's name, help, and the project which contains its code will now also show up in the `west --help` output. If you share the updated repositories with others, they'll be able to use it, too.

2.11.10 Building, Flashing and Debugging

Zephyr provides several *west extension commands* for building, flashing, and interacting with Zephyr programs running on a board: `build`, `flash`, `debug`, `debugserver` and `attach`.

For information on adding board support for the flashing and debugging commands, see *Flash and debug support* in the board porting guide.

Building: `west build`

> **Tip**
>
> Run `west build -h` for a quick overview.

The `build` command helps you build Zephyr applications from source. You can use *west config* to configure its behavior.

Its default behavior tries to "do what you mean":

- If there is a Zephyr build directory named `build` in your current working directory, it is incrementally re-compiled. The same is true if you run `west build` from a Zephyr build directory.
- Otherwise, if you run `west build` from a Zephyr application's source directory and no build directory is found, a new one is created and the application is compiled in it.

Basics The easiest way to use `west build` is to go to an application's root directory (i.e. the folder containing the application's `CMakeLists.txt`) and then run:

```
west build -b <BOARD>
```

Where `<BOARD>` is the name of the board you want to build for. This is exactly the same name you would supply to CMake if you were to invoke it with: `cmake -DBOARD=<BOARD>`.

> **Tip**
>
> You can use the *west boards* command to list all supported boards.

A build directory named `build` will be created, and the application will be compiled there after `west build` runs CMake to create a build system in that directory. If `west build` finds an existing build directory, the application is incrementally re-compiled there without re-running CMake. You can force CMake to run again with `--cmake`.

You don't need to use the `--board` option if you've already got an existing build directory; `west build` can figure out the board from the CMake cache. For new builds, the `--board` option, *BOARD* environment variable, or `build.board` configuration option are checked (in that order).

Sysbuild (multi-domain builds) *Sysbuild (System build)* can be used to create a multi-domain build system combining multiple images for a single or multiple boards.

Use `--sysbuild` to select the *Sysbuild (System build)* build infrastructure with `west build` to build multiple domains.

More detailed information regarding the use of sysbuild can be found in the *Sysbuild (System build)* guide.

Tip

The `build.sysbuild` configuration option can be enabled to tell `west build` to default build using sysbuild. `--no-sysbuild` can be used to disable sysbuild for a specific build.

`west build` will build all domains through the top-level build folder of the domains specified by sysbuild.

A single domain from a multi-domain project can be built by using `--domain` argument.

Examples Here are some `west build` usage examples, grouped by area.

Forcing CMake to Run Again To force a CMake re-run, use the `--cmake` (or `-c`) option:

```
west build -c
```

Setting a Default Board To configure `west build` to build for the `reel_board` by default:

```
west config build.board reel_board
```

(You can use any other board supported by Zephyr here; it doesn't have to be `reel_board`.)

Setting Source and Build Directories To set the application source directory explicitly, give its path as a positional argument:

```
west build -b <BOARD> path/to/source/directory
```

To set the build directory explicitly, use `--build-dir` (or `-d`):

```
west build -b <BOARD> --build-dir path/to/build/directory
```

To change the default build directory from `build`, use the `build.dir-fmt` configuration option. This lets you name build directories using format strings, like this:

```
west config build.dir-fmt "build/{board}/{app}"
```

With the above, running `west build -b reel_board samples/hello_world` will use build directory `build/reel_board/hello_world`. See *Configuration Options* for more details on this option.

Setting the Build System Target To specify the build system target to run, use `--target` (or `-t`).

For example, on host platforms with QEMU, you can use the `run` target to build and run the hello_world sample for the emulated qemu_x86 board in one command:

```
west build -b qemu_x86 -t run samples/hello_world
```

As another example, to use `-t` to list all build system targets:

```
west build -t help
```

As a final example, to use `-t` to run the `pristine` target, which deletes all the files in the build directory:

```
west build -t pristine
```

Pristine Builds A *pristine* build directory is essentially a new build directory. All byproducts from previous builds have been removed.

To force `west build` make the build directory pristine before re-running CMake to generate a build system, use the `--pristine=always` (or `-p=always`) option.

Giving `--pristine` or `-p` without a value has the same effect as giving it the value `always`. For example, these commands are equivalent:

```
west build -p -b reel_board samples/hello_world
west build -p=always -b reel_board samples/hello_world
```

By default, `west build` makes no attempt to detect if the build directory needs to be made pristine. This can lead to errors if you do something like try to reuse a build directory for a different `--board`.

Using `--pristine=auto` makes `west build` detect some of these situations and make the build directory pristine before trying the build.

Tip

You can run `west config build.pristine always` to always do a pristine build, or `west config build.pristine never` to disable the heuristic. See the `west build` *Configuration Options* for details.

Verbose Builds To print the CMake and compiler commands run by `west build`, use the global west verbosity option, `-v`:

```
west -v build -b reel_board samples/hello_world
```

One-Time CMake Arguments To pass additional arguments to the CMake invocation performed by `west build`, pass them after a `--` at the end of the command line.

Important

Passing additional CMake arguments like this forces `west build` to re-run the CMake build configuration step, even if a build system has already been generated. This will make incremental builds slower (but still much faster than building from scratch).

After using `--` once to generate the build directory, use `west build -d <build-dir>` on subsequent runs to do incremental builds.

Alternatively, make your CMake arguments permanent as described in the next section; it will not slow down incremental builds.

For example, to use the Unix Makefiles CMake generator instead of Ninja (which `west build` uses by default), run:

```
west build -b reel_board -- -G'Unix Makefiles'
```

To use Unix Makefiles and set CMAKE_VERBOSE_MAKEFILE to ON:

```
west build -b reel_board -- -G'Unix Makefiles' -DCMAKE_VERBOSE_MAKEFILE=ON
```

Notice how the `--` only appears once, even though multiple CMake arguments are given. All command-line arguments to `west build` after a `--` are passed to CMake.

To set *DTC_OVERLAY_FILE* to `enable-modem.overlay`, using that file as a *devicetree overlay*:

```
west build -b reel_board -- -DDTC_OVERLAY_FILE=enable-modem.overlay
```

To merge the `file.conf` Kconfig fragment into your build's `.config`:

```
west build -- -DEXTRA_CONF_FILE=file.conf
```

Permanent CMake Arguments The previous section describes how to add CMake arguments for a single `west build` command. If you want to save CMake arguments for `west build` to use every time it generates a new build system instead, you should use the `build.cmake-args` configuration option. Whenever `west build` runs CMake to generate a build system, it splits this option's value according to shell rules and includes the results in the `cmake` command line.

Remember that, by default, `west build` **tries to avoid generating a new build system if one is present** in your build directory. Therefore, you need to either delete any existing build directories or do a *pristine build* after setting `build.cmake-args` to make sure it will take effect.

For example, to always enable **CMAKE_EXPORT_COMPILE_COMMANDS**, you can run:

```
west config build.cmake-args -- -DCMAKE_EXPORT_COMPILE_COMMANDS=ON
```

(The extra `--` is used to force the rest of the command to be treated as a positional argument. Without it, *west config* would treat the `-DVAR=VAL` syntax as a use of its `-D` option.)

To enable **CMAKE_VERBOSE_MAKEFILE**, so CMake always produces a verbose build system:

```
west config build.cmake-args -- -DCMAKE_VERBOSE_MAKEFILE=ON
```

To save more than one argument in `build.cmake-args`, use a single string whose value can be split into distinct arguments (`west build` uses the Python function shlex.split() internally to split the value).

For example, to enable both **CMAKE_EXPORT_COMPILE_COMMANDS** and **CMAKE_VERBOSE_MAKEFILE**:

```
west config build.cmake-args -- "-DCMAKE_EXPORT_COMPILE_COMMANDS=ON -DCMAKE_VERBOSE_
↪MAKEFILE=ON"
```

If you want to save your CMake arguments in a separate file instead, you can combine CMake's `-C <initial-cache>` option with `build.cmake-args`. For instance, another way to set the options used in the previous example is to create a file named `~/my-cache.cmake` with the following contents:

```
set(CMAKE_EXPORT_COMPILE_COMMANDS ON CACHE BOOL "")
set(CMAKE_VERBOSE_MAKEFILE ON CACHE BOOL "")
```

Then run:

```
west config build.cmake-args "-C ~/my-cache.cmake"
```

See the cmake(1) manual page and the set() command documentation for more details.

Build tool arguments Use `-o` to pass options to the underlying build tool.

This works with both `ninja` (*the default*) and `make` based build systems.

For example, to pass `-dexplain` to `ninja`:

```
west build -o=-dexplain
```

As another example, to pass `--keep-going` to `make`:

```
west build -o=--keep-going
```

Note that using `-o=--foo` instead of `-o --foo` is required to prevent `--foo` from being treated as a `west build` option.

Build parallelism By default, `ninja` uses all of your cores to build, while `make` uses only one. You can control this explicitly with the `-j` option supported by both tools.

For example, to build with 4 cores:

```
west build -o=-j4
```

The `-o` option is described further in the previous section.

Build a single domain In a multi-domain build with hello_world and MCUboot, you can use `--domain hello_world` to only build this domain:

```
west build --sysbuild --domain hello_world
```

The `--domain` argument can be combined with the `--target` argument to build the specific target for the target, for example:

```
west build --sysbuild --domain hello_world --target help
```

Use a snippet See *Using Snippets*.

Configuration Options You can *configure* `west build` using these options.

Option	Description
build.board	String. If given, this the board used by *west build* when --board is not given and BOARD is unset in the environment.
build.board_warn	Boolean, default true. If false, disables warnings when west build can't figure out the target board.
build.cmake-args	String. If present, the value will be split according to shell rules and passed to CMake whenever a new build system is generated. See *Permanent CMake Arguments*.
build.dir-fmt	String, default build. The build folder format string, used by west whenever it needs to create or locate a build folder. The currently available arguments are: • board: The board name • source_dir: The relative path from the current working directory to the source directory. If the current working directory is inside the source directory this will be set to an empty string. • app: The name of the source directory.
build.generator	String, default Ninja. The CMake Generator to use to create a build system. (To set a generator for a single build, see the *above example*)
build.guess-dir	String, instructs west whether to try to guess what build folder to use when build.dir-fmt is in use and not enough information is available to resolve the build folder name. Can take these values: • never (default): Never try to guess, bail out instead and require the user to provide a build folder with -d. • runners: Try to guess the folder when using any of the 'runner' commands. These are typically all commands that invoke an external tool, such as flash and debug.
build.pristine	String. Controls the way in which west build may clean the build folder before building. Can take the following values: • never (default): Never automatically make the build folder pristine. • auto: west build will automatically make the build folder pristine before building, if a build system is present and the build would fail otherwise (e.g. the user has specified a different board or application from the one previously used to make the build directory). • always: Always make the build folder pristine before building, if a build system is present.
build.sysbuild	Boolean, default false. If true, build application using the sysbuild infrastructure.

Flashing: west flash

Tip

Run west flash -h for additional help.

Basics From a Zephyr build directory, re-build the binary and flash it to your board:

```
west flash
```

Without options, the behavior is the same as ninja flash (or make flash, etc.).

To specify the build directory, use `--build-dir` (or `-d`):

```
west flash --build-dir path/to/build/directory
```

If you don't specify the build directory, `west flash` searches for one in `build`, then the current working directory. If you set the `build.dir-fmt` configuration option (see *Setting Source and Build Directories*), `west flash` searches there instead of `build`.

Choosing a Runner If your board's Zephyr integration supports flashing with multiple programs, you can specify which one to use using the `--runner` (or `-r`) option. For example, if West flashes your board with `nrfjprog` by default, but it also supports JLink, you can override the default with:

```
west flash --runner jlink
```

You can override the default flash runner at build time by using the `BOARD_FLASH_RUNNER` CMake variable, and the debug runner with `BOARD_DEBUG_RUNNER`.

For example:

```
# Set the default runner to "jlink", overriding the board's
# usual default.
west build [...] -- -DBOARD_FLASH_RUNNER=jlink
```

See *One-Time CMake Arguments* and *Permanent CMake Arguments* for more information on setting CMake arguments.

See *Flash and debug runners* below for more information on the `runner` library used by West. The list of runners which support flashing can be obtained with `west flash -H`; if run from a build directory or with `--build-dir`, this will print additional information on available runners for your board.

Configuration Overrides The CMake cache contains default values West uses while flashing, such as where the board directory is on the file system, the path to the zephyr binaries to flash in several formats, and more. You can override any of this configuration at runtime with additional options.

For example, to override the HEX file containing the Zephyr image to flash (assuming your runner expects a HEX file), but keep other flash configuration at default values:

```
west flash --hex-file path/to/some/other.hex
```

The `west flash -h` output includes a complete list of overrides supported by all runners.

Runner-Specific Overrides Each runner may support additional options related to flashing. For example, some runners support an `--erase` flag, which mass-erases the flash storage on your board before flashing the Zephyr image.

To view all of the available options for the runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west flash --context
```

Important

Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

When running West outside of a build directory, `west flash -H` just prints a list of runners. You can use `west flash -H -r <runner-name>` to print usage information for options supported by that runner.

For example, to print usage information about the `jlink` runner:

```
west flash -H -r jlink
```

Multi-domain flashing When a *Sysbuild (multi-domain builds)* folder is detected, then `west flash` will flash all domains in the order defined by sysbuild.

It is possible to flash the image from a single domain in a multi-domain project by using `--domain`.

For example, in a multi-domain build with hello_world and MCUboot, you can use the `--domain hello_world` domain to only flash only the image from this domain:

```
west flash --domain hello_world
```

Debugging: `west debug`, `west debugserver`

> **Tip**
>
> Run `west debug -h` or `west debugserver -h` for additional help.

Basics From a Zephyr build directory, to attach a debugger to your board and open up a debug console (e.g. a GDB session):

```
west debug
```

To attach a debugger to your board and open up a local network port you can connect a debugger to (e.g. an IDE debugger):

```
west debugserver
```

Without options, the behavior is the same as `ninja debug` and `ninja debugserver` (or `make debug`, etc.).

To specify the build directory, use `--build-dir` (or `-d`):

```
west debug --build-dir path/to/build/directory
west debugserver --build-dir path/to/build/directory
```

If you don't specify the build directory, these commands search for one in `build`, then the current working directory. If you set the `build.dir-fmt` configuration option (see *Setting Source and Build Directories*), `west debug` searches there instead of `build`.

Choosing a Runner If your board's Zephyr integration supports debugging with multiple programs, you can specify which one to use using the `--runner` (or `-r`) option. For example, if West debugs your board with `pyocd-gdbserver` by default, but it also supports JLink, you can override the default with:

```
west debug --runner jlink
west debugserver --runner jlink
```

See *Flash and debug runners* below for more information on the `runner` library used by West. The list of runners which support debugging can be obtained with `west debug -H`; if run from a

build directory or with `--build-dir`, this will print additional information on available runners for your board.

Configuration Overrides The CMake cache contains default values West uses for debugging, such as where the board directory is on the file system, the path to the zephyr binaries containing symbol tables, and more. You can override any of this configuration at runtime with additional options.

For example, to override the ELF file containing the Zephyr binary and symbol tables (assuming your runner expects an ELF file), but keep other debug configuration at default values:

```
west debug --elf-file path/to/some/other.elf
west debugserver --elf-file path/to/some/other.elf
```

The `west debug -h` output includes a complete list of overrides supported by all runners.

Runner-Specific Overrides Each runner may support additional options related to debugging. For example, some runners support flags which allow you to set the network ports used by debug servers.

To view all of the available options for the runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west debug --context
```

(The command `west debugserver --context` will print the same output.)

Important

Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

When running West outside of a build directory, `west debug -H` just prints a list of runners. You can use `west debug -H -r <runner-name>` to print usage information for options supported by that runner.

For example, to print usage information about the `jlink` runner:

```
west debug -H -r jlink
```

Multi-domain debugging `west debug` can only debug a single domain at a time. When a *Sysbuild (multi-domain builds)* folder is detected, `west debug` will debug the `default` domain specified by sysbuild.

The default domain will be the application given as the source directory. See the following example:

```
west build --sysbuild path/to/source/directory
```

For example, when building `hello_world` with MCUboot using sysbuild, `hello_world` becomes the default domain:

```
west build --sysbuild samples/hello_world
```

So to debug `hello_world` you can do:

```
west debug
```

or:

```
west debug --domain hello_world
```

If you wish to debug MCUboot, you must explicitly specify MCUboot as the domain to debug:

```
west debug --domain mcuboot
```

Flash and debug runners

The flash and debug commands use Python wrappers around various *Flash & Debug Host Tools*. These wrappers are all defined in a Python library at scripts/west_commands/runners. Each wrapper is called a *runner*. Runners can flash and/or debug Zephyr programs.

The central abstraction within this library is `ZephyrBinaryRunner`, an abstract class which represents runners. The set of available runners is determined by the imported subclasses of `ZephyrBinaryRunner`. `ZephyrBinaryRunner` is available in the `runners.core` module; individual runner implementations are in other submodules, such as `runners.nrfjprog`, `runners.openocd`, etc.

Running Robot Framework tests: `west robot`

> **Tip**
>
> Run `west robot -h` for additional help.

Basics Currently the command supports only one runner which is using `renode-test`, (essentially a wrapper for running Robot tests in Renode), but can be easily extended by adding other runners.

From a Zephyr build directory, to run a Robot test suite:

```
west robot --runner=renode-robot --testsuite path/to/testsuite.robot
```

This will run all tests from testsuite.robot and print output provided by Robot Framework.

To pass additional parameters to Renode use `--renode-robot-args` switch. For example to show Renode logs in addition to Robot Framework's output:

> west robot –runner=renode-robot –testsuite path/to/testsuite.robot –renode-robot-arg="–show-log"

Runner-Specific Overrides To view all of the available options for the Robot runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west robot --runner=renode-robot --context
```

To view all available options "renode-test" runner supports, use:

```
west robot --runner=renode-robot --renode-robot-help
```

Simulating a board with: `west simulate`

Basics Currently the command supports only one runner which is using Renode, but can be easily extended by adding other runners.

From a Zephyr build directory, to run the built binary:

```
west simulate --runner=renode
```

This will start Renode and configure simulation based on a default `.resc` script for the current platform with the zephyr.elf file loaded by default. The simulation then can be started by typing "start" or "s" in Renode's Monitor. This can also be done by passing a command to Renode, using an argument provided by the runner:

west simulate –runner=renode –renode-command start

To pass an argument to Renode itself, for example to start Renode in console mode instead of a separate window:

west simulate –runner=renode –renode-arg="–console"

From that point on Renode can be used normally in both console and window modes. For details on using Renode see Renode - documentation.

Runner-Specific Overrides To view all of the available options supported by the runners, as well as their usage information, use `--context` (or"-H"):

```
west simulate --runner=renode --context
```

To view all available options Renode supports, use:

```
west simulate --runner=renode --renode-help
```

Hacking

This section documents the `runners.core` module used by the flash and debug commands. This is the core abstraction used to implement support for these features.

Warning

These APIs are provided for reference, but they are more "shared code" used to implement multiple extension commands than a stable API.

Developers can add support for new ways to flash and debug Zephyr programs by implementing additional runners. To get this support into upstream Zephyr, the runner should be added into a new or existing `runners` module, and imported from `runners/__init__.py`.

Note

The test cases in scripts/west_commands/tests add unit test coverage for the runners package and individual runner classes.

Please try to add tests when adding new runners. Note that if your changes break existing test cases, CI testing on upstream pull requests will fail.

Zephyr binary runner core interfaces

This provides the core ZephyrBinaryRunner class meant for public use, as well as some other helpers for concrete runner classes.

class runners.core.**BuildConfiguration**(*build_dir: str*)

This helper class provides access to build-time configuration.

Configuration options can be read as if the object were a dict, either object['CONFIG_FOO'] or object.get('CONFIG_FOO').

Kconfig configuration values are available (parsed from .config).

getboolean(*option*)

If a boolean option is explicitly set to y or n, returns its value. Otherwise, falls back to False.

class runners.core.**DeprecatedAction**(*option_strings*, *dest*, *nargs=None*, *const=None*, *default=None*, *type=None*, *choices=None*, *required=False*, *help=None*, *metavar=None*)

class runners.core.**FileType**(*value*, *names=<not given>*, **values*, *module=None*, *qualname=None*, *type=None*, *start=1*, *boundary=None*)

exception runners.core.**MissingProgram**(*program*)

FileNotFoundError subclass for missing program dependencies.

No significant changes from the parent FileNotFoundError; this is useful for explicitly signaling that the file in question is a program that some class requires to proceed.

The filename attribute contains the missing program.

class runners.core.**NetworkPortHelper**

Helper class for dealing with local IP network ports.

get_unused_ports(*starting_from*)

Find unused network ports, starting at given values.

starting_from is an iterable of ports the caller would like to use.

The return value is an iterable of ports, in the same order, using the given values if they were unused, or the next sequentially available unused port otherwise.

Ports may be bound between this call's check and actual usage, so callers still need to handle errors involving returned ports.

class runners.core.**RunnerCaps**(*commands: ~typing.Set[str] = <factory>*, *dev_id: bool = False*, *flash_addr: bool = False*, *erase: bool = False*, *reset: bool = False*, *extload: bool = False*, *tool_opt: bool = False*, *file: bool = False*, *hide_load_files: bool = False*)

This class represents a runner class's capabilities.

Each capability is represented as an attribute with the same name. Flag attributes are True or False.

Available capabilities:

- commands: set of supported commands; default is {'flash', 'debug', 'debugserver', 'attach', 'simulate', 'robot'}.
- dev_id: whether the runner supports device identifiers, in the form of an -i, –dev-id option. This is useful when the user has multiple debuggers connected to a single computer, in order to select which one will be used with the command provided.
- flash_addr: whether the runner supports flashing to an arbitrary address. Default is False. If true, the runner must honor the –dt-flash option.
- erase: whether the runner supports an –erase option, which does a mass-erase of the entire addressable flash on the target before flashing. On multi-core SoCs, this may only erase portions of flash specific the actual target core. (This option can be useful for things like clearing out old settings values or other subsystem state that may affect

the behavior of the zephyr image. It is also sometimes needed by SoCs which have flash-like areas that can't be sector erased by the underlying tool before flashing; UICR on nRF SoCs is one example.)

- reset: whether the runner supports a –reset option, which resets the device after a flash operation is complete.
- extload: whether the runner supports a –extload option, which must be given one time and is passed on to the underlying tool that the runner wraps.
- tool_opt: whether the runner supports a –tool-opt (-O) option, which can be given multiple times and is passed on to the underlying tool that the runner wraps.
- file: whether the runner supports a –file option, which specifies exactly the file that should be used to flash, overriding any default discovered in the build directory.
- hide_load_files: whether the elf/hex/bin file arguments should be hidden.

class runners.core.**RunnerConfig**(*build_dir: str*, *board_dir: str*, *elf_file: str | None*, *exe_file: str | None*, *hex_file: str | None*, *bin_file: str | None*, *uf2_file: str | None*, *file: str | None*, *file_type:* FileType *| None = FileType.OTHER*, *gdb: str | None = None*, *openocd: str | None = None*, *openocd_search: List[str] = []*)

Runner execution-time configuration.

This is a common object shared by all runners. Individual runners can register specific configuration options using their do_add_parser() hooks.

bin_file: str | None
Alias for field number 5

board_dir: str
Alias for field number 1

build_dir: str
Alias for field number 0

elf_file: str | None
Alias for field number 2

exe_file: str | None
Alias for field number 3

file: str | None
Alias for field number 7

file_type: *FileType* **| None**
Alias for field number 8

gdb: str | None
Alias for field number 9

hex_file: str | None
Alias for field number 4

openocd: str | None
Alias for field number 10

openocd_search: List[str]
Alias for field number 11

uf2_file: str | None
Alias for field number 6

class runners.core.**SysbuildConfiguration**(*build_dir: str*)

This helper class provides access to sysbuild-time configuration.

Configuration options can be read as if the object were a dict, either object['SB_CONFIG_FOO'] or object.get('SB_CONFIG_FOO').

Kconfig configuration values are available (parsed from .config).

class runners.core.**ZephyrBinaryRunner**(*cfg:* RunnerConfig)

Abstract superclass for binary runners (flashers, debuggers).

Note: this class's API has changed relatively rarely since it as added, but it is not considered a stable Zephyr API, and may change without notice.

With some exceptions, boards supported by Zephyr must provide generic means to be flashed (have a Zephyr firmware binary permanently installed on the device for running) and debugged (have a breakpoint debugger and program loader on a host workstation attached to a running target).

This is supported by four top-level commands managed by the Zephyr build system:

- 'flash': flash a previously configured binary to the board, start execution on the target, then return.
- 'debug': connect to the board via a debugging protocol, program the flash, then drop the user into a debugger interface with symbol tables loaded from the current binary, and block until it exits.
- 'debugserver': connect via a board-specific debugging protocol, then reset and halt the target. Ensure the user is now able to connect to a debug server with symbol tables loaded from the binary.
- 'attach': connect to the board via a debugging protocol, then drop the user into a debugger interface with symbol tables loaded from the current binary, and block until it exits. Unlike 'debug', this command does not program the flash.

This class provides an API for these commands. Every subclass is called a 'runner' for short. Each runner has a name (like 'pyocd'), and declares commands it can handle (like 'flash'). Boards (like 'nrf52dk/nrf52832') declare which runner(s) are compatible with them to the Zephyr build system, along with information on how to configure the runner to work with the board.

The build system will then place enough information in the build directory to create and use runners with this class's create() method, which provides a command line argument parsing API. You can also create runners by instantiating subclasses directly.

In order to define your own runner, you need to:

1. Define a ZephyrBinaryRunner subclass, and implement its abstract methods. You may need to override capabilities().
2. Make sure the Python module defining your runner class is imported, e.g. by editing this package's __init__.py (otherwise, get_runners() won't work).
3. Give your runner's name to the Zephyr build system in your board's board.cmake.

Additional advice:

- If you need to import any non-standard-library modules, make sure to catch ImportError and defer complaints about it to a RuntimeError if one is missing. This avoids affecting users that don't require your runner, while still making it clear what went wrong to users that do require it that don't have the necessary modules installed.
- If you need to ask the user something (e.g. using input()), do it in your create() classmethod, not do_run(). That ensures your __init__() really has everything it needs to call do_run(), and also avoids calling input() when not instantiating within a command line application.

- Use self.logger to log messages using the standard library's logging API; your logger is named "runner.<your-runner-name()>"

For command-line invocation from the Zephyr build system, runners define their own argparse-based interface through the common add_parser() (and runner-specific do_add_parser() it delegates to), and provide a way to create instances of themselves from a RunnerConfig and parsed runner-specific arguments via create().

Runners use a variety of host tools and configuration values, the user interface to which is abstracted by this class. Each runner subclass should take any values it needs to execute one of these commands in its constructor. The actual command execution is handled in the run() method.

`classmethod add_parser`(*parser*)

Adds a sub-command parser for this runner.

The given object, parser, is a sub-command parser from the argparse module. For more details, refer to the documentation for argparse.ArgumentParser.add_subparsers().

The lone common optional argument is:

- –dt-flash (if the runner capabilities includes flash_addr)

Runner-specific options are added through the do_add_parser() hook.

`property build_conf:` *BuildConfiguration*

Get a BuildConfiguration for the build directory.

`call`(*cmd: List[str]*, ***kwargs*) → int

Subclass subprocess.call() wrapper.

Subclasses should use this method to run command in a subprocess and get its return code, rather than using subprocess directly, to keep accurate debug logs.

`classmethod capabilities`() → *RunnerCaps*

Returns a RunnerCaps representing this runner's capabilities.

This implementation returns the default capabilities.

Subclasses should override appropriately if needed.

`cfg`

RunnerConfig for this instance.

`check_call`(*cmd: List[str]*, ***kwargs*)

Subclass subprocess.check_call() wrapper.

Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using subprocess directly, to keep accurate debug logs.

`check_output`(*cmd: List[str]*, ***kwargs*) → bytes

Subclass subprocess.check_output() wrapper.

Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using subprocess directly, to keep accurate debug logs.

`classmethod create`(*cfg:* RunnerConfig, *args: Namespace*) → *ZephyrBinaryRunner*

Create an instance from command-line arguments.

- `cfg`: runner configuration (pass to superclass __init__)
- `args`: arguments parsed from execution environment, as specified by `add_parser()`.

`classmethod dev_id_help`() → str

Get the ArgParse help text for the –dev-id option.

`abstract classmethod do_add_parser`(*parser*)

Hook for adding runner-specific options.

`abstract classmethod do_create`(*cfg:* RunnerConfig, *args: Namespace*) → *ZephyrBinaryRunner*

Hook for instance creation from command line arguments.

`abstract do_run`(*command: str*, ***kwargs*)

Concrete runner; run() delegates to this. Implement in subclasses.

In case of an unsupported command, raise a ValueError.

`ensure_output`(*output_type: str*) → None

Ensure self.cfg has a particular output artifact.

For example, ensure_output('bin') ensures that self.cfg.bin_file refers to an existing file. Errors out if it's missing or undefined.

Parameters

`output_type` – string naming the output type

`classmethod extload_help`() → str

Get the ArgParse help text for the –extload option.

`static flash_address_from_build_conf`(*build_conf:* BuildConfiguration)

If CONFIG_HAS_FLASH_LOAD_OFFSET is n in build_conf, return the CONFIG_FLASH_BASE_ADDRESS value. Otherwise, return CONFIG_FLASH_BASE_ADDRESS + CONFIG_FLASH_LOAD_OFFSET.

`static get_flash_address`(*args: Namespace*, *build_conf:* BuildConfiguration, *default: int = 0*) → int

Helper method for extracting a flash address.

If args.dt_flash is true, returns the address obtained from ZephyrBinaryRunner.flash_address_from_build_conf(build_conf).

Otherwise (when args.dt_flash is False), the default value is returned.

`static get_runners`() → List[Type[*ZephyrBinaryRunner*]]

Get a list of all currently defined runner classes.

`logger`

logging.Logger for this instance.

`abstract classmethod name`() → str

Return this runner's user-visible name.

When choosing a name, pick something short and lowercase, based on the name of the tool (like openocd, jlink, etc.) or the target architecture/board (like xtensa etc.).

`popen_ignore_int`(*cmd: List[str]*, ***kwargs*) → Popen

Spawn a child command, ensuring it ignores SIGINT.

The returned subprocess.Popen object must be manually terminated.

`static require`(*program: str*, *path: str | None = None*) → str

Require that a program is installed before proceeding.

Parameters

- `program` – name of the program that is required, or path to a program binary.
- `path` – PATH where to search for the program binary. By default check on the system PATH.

If `program` is an absolute path to an existing program binary, this call succeeds. Otherwise, try to find the program by name on the system PATH or in the given PATH, if provided.

If the program can be found, its path is returned. Otherwise, raises MissingProgram.

`run`(*command: str*, ***kwargs*)

Runs command ('flash', 'debug', 'debugserver', 'attach').

This is the main entry point to this runner.

`run_client`(*client*, ***kwargs*)

Run a client that handles SIGINT.

`run_server_and_client`(*server*, *client*, ***kwargs*)

Run a server that ignores SIGINT, and a client that handles it.

This routine portably:

- creates a Popen object for the `server` command which ignores SIGINT
- runs `client` in a subprocess while temporarily ignoring SIGINT
- cleans up the server after the client exits.
- the keyword arguments, if any, will be passed down to both server and client subprocess calls

It's useful to e.g. open a GDB server and client.

`property sysbuild_conf: SysbuildConfiguration`

Get a SysbuildConfiguration for the sysbuild directory.

`property thread_info_enabled: bool`

Returns True if self.build_conf has CONFIG_DEBUG_THREAD_INFO enabled.

`classmethod tool_opt_help`() → str

Get the ArgParse help text for the –tool-opt option.

Doing it By Hand

If you prefer not to use West to flash or debug your board, simply inspect the build directory for the binaries output by the build system. These will be named something like `zephyr/zephyr.elf`, `zephyr/zephyr.hex`, etc., depending on your board's build system integration. These binaries may be flashed to a board using alternative tools of your choice, or used for debugging as needed, e.g. as a source of symbol tables.

By default, these West commands rebuild binaries before flashing and debugging. This can of course also be accomplished using the usual targets provided by Zephyr's build system (in fact, that's how these commands do it).

2.11.11 Signing Binaries

The `west sign` *extension* command can be used to sign a Zephyr application binary for consumption by a bootloader using an external tool. In some configurations, `west sign` is also used to invoke an external, post-processing tool that "stitches" the final components of the image together. Run `west sign -h` for command line help.

MCUboot / imgtool

The Zephyr build system has special support for signing binaries for use with the MCUboot bootloader using the imgtool program provided by its developers. You can both build and sign this type of application binary in one step by setting some Kconfig options. If you do, `west flash` will use the signed binaries.

If you use this feature, you don't need to run `west sign` yourself; the build system will do it for you.

Here is an example workflow, which builds and flashes MCUboot, as well as the hello_world application for chain-loading by MCUboot. Run these commands from the `zephyrproject` workspace you created in the *Getting Started Guide*.

```
west build -b YOUR_BOARD bootloader/mcuboot/boot/zephyr -d build-mcuboot
west build -b YOUR_BOARD zephyr/samples/hello_world -d build-hello-signed -- \
     -DCONFIG_BOOTLOADER_MCUBOOT=y \
     -DCONFIG_MCUBOOT_SIGNATURE_KEY_FILE=\"bootloader/mcuboot/root-rsa-2048.pem\"

west flash -d build-mcuboot
west flash -d build-hello-signed
```

Notes on the above commands:

- `YOUR_BOARD` should be changed to match your board
- The `CONFIG_MCUBOOT_SIGNATURE_KEY_FILE` value is the insecure default provided and used by MCUboot for development and testing
- You can change the `hello_world` application directory to any other application that can be loaded by MCUboot, such as the smp-svr sample.

For more information on these and other related configuration options, see:

- `CONFIG_BOOTLOADER_MCUBOOT`: build the application for loading by MCUboot
- `CONFIG_MCUBOOT_SIGNATURE_KEY_FILE`: the key file to use with `west sign`. If you have your own key, change this appropriately
- `CONFIG_MCUBOOT_EXTRA_IMGTOOL_ARGS`: optional additional command line arguments for `imgtool`
- `CONFIG_MCUBOOT_GENERATE_CONFIRMED_IMAGE`: also generate a confirmed image, which may be more useful for flashing in production environments than the OTA-able default image
- On Windows, if you get "Access denied" issues, the recommended fix is to run `pip3 install imgtool`, then retry with a pristine build directory.

If your `west flash` *runner* uses an image format supported by imgtool, you should see something like this on your device's serial console when you run `west flash -d build-mcuboot`:

```
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1  ***
[00:00:00.004,669] <inf> mcuboot: Starting bootloader
[00:00:00.011,169] <inf> mcuboot: Primary image: magic=unset, swap_type=0x1, copy_done=0x3,␣
↪image_ok=0x3
[00:00:00.021,636] <inf> mcuboot: Boot source: none
[00:00:00.027,313] <wrn> mcuboot: Failed reading image headers; Image=0
[00:00:00.035,064] <err> mcuboot: Unable to find bootable image
```

Then, you should see something like this when you run `west flash -d build-hello-signed`:

```
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1  ***
[00:00:00.004,669] <inf> mcuboot: Starting bootloader
[00:00:00.011,169] <inf> mcuboot: Primary image: magic=unset, swap_type=0x1, copy_done=0x3,␣
↪image_ok=0x3
```

(continues on next page)

(continued from previous page)

```
[00:00:00.021,636] <inf> mcuboot: Boot source: none
[00:00:00.027,374] <inf> mcuboot: Swap type: none
[00:00:00.115,142] <inf> mcuboot: Bootloader chainload address offset: 0xc000
[00:00:00.123,168] <inf> mcuboot: Jumping to the first image slot
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1  ***
Hello World! nrf52840dk_nrf52840
```

Whether `west flash` supports this feature depends on your runner. The `nrfjprog` and `pyocd` runners work with the above flow. If your runner does not support this flow and you would like it to, please send a patch or file an issue for adding support.

Extending signing externally

The signing script used when running `west flash` can be extended or replaced to change features or introduce different signing mechanisms. By default with MCUboot enabled, signing is setup by the `cmake/mcuboot.cmake` file in Zephyr which adds extra post build commands for generating the signed images. The file used for signing can be replaced from a sysbuild scope (if being used) or from a zephyr/zephyr module scope, the priority of which is:

- Sysbuild
- Zephyr property
- Default MCUboot script (if enabled)

From sysbuild, `-D<target>_SIGNING_SCRIPT` can be used to set a signing script for a specific image or `-DSIGNING_SCRIPT` can be used to set a signing script for all images, for example:

```
west build -b <board> <application> -DSIGNING_SCRIPT=<file>
```

The zephyr property method is achieved by adjusting the `SIGNING_SCRIPT` property on the *zephyr_property_target*, ideally from by a module by using:

```
if(CONFIG_BOOTLOADER_MCUBOOT)
  set_target_properties(zephyr_property_target PROPERTIES SIGNING_SCRIPT ${CMAKE_CURRENT_
↪LIST_DIR}/custom_signing.cmake)
endif()
```

This will include the custom signing CMake file instead of the default Zephyr one when projects are built with MCUboot signing support enabled. The base Zephyr MCUboot signing file can be used as a reference for creating a new signing system or extending the default behaviour.

rimage

rimage configuration uses a different approach that does not rely on Kconfig or CMake but on *west config* instead, similar to *Permanent CMake Arguments*.

Signing involves a number of "wrapper" scripts stacked on top of each other: `west flash` invokes `west build` which invokes `cmake` and `ninja` which invokes `west sign` which invokes `imgtool` or `rimage`. As long as the signing parameters desired are the default ones and fairly static, these indirections are not a problem. On the other hand, passing `imgtool` or `rimage` options through all these layers can causes issues typical when the layers don't abstract anything. First, this usually requires boilerplate code in each layer. Quoting whitespace or other special characters through all the wrappers can be difficult. Reproducing a lower `west sign` command to debug some build-time issue can be very time-consuming: it requires at least enabling and searching verbose build logs to find which exact options were used. Copying these options from the build logs can be unreliable: it may produce different results because of subtle environment differences. Last and worst: new signing feature and options are impossible to use until more boilerplate code has been added in each layer.

To avoid these issues, `rimage` parameters can bet set in `west config` instead. Here's a `workspace/.west/config` example:

```
[sign]
# Not needed when invoked from CMake
tool = rimage

[rimage]
# Quoting is optional and works like in Unix shells
# Not needed when rimage can be found in the default PATH
path = "/home/me/zworkspace/build-rimage/rimage"

# Not needed when using the default development key
extra-args = -i 4 -k 'keys/key argument with space.pem'
```

In order to support quoting, values are parsed by Python's `shlex.split()` like in *One-Time CMake Arguments*.

The `extra-args` are passed directly to the `rimage` command. The example above has the same effect as appending them on command line after `--` like this: `west sign --tool rimage -- -i 4 -k 'keys/key argument with space.pem'`. In case both are used, the command-line arguments go last.

2.11.12 Additional Zephyr extension commands

This page documents miscellaneous *Zephyr Extensions*.

Listing boards: `west boards`

The `boards` command can be used to list the boards that are supported by Zephyr without having to resort to additional sources of information.

It can be run by typing:

```
west boards
```

This command lists all supported boards in a default format. If you prefer to specify the display format yourself you can use the `--format` (or `-f`) flag:

```
west boards -f "{arch}:{name}"
```

Additional help about the formatting options can be found by running:

```
west boards -h
```

Shell completion scripts: `west completion`

The `completion` extension command outputs shell completion scripts that can then be used directly to enable shell completion for the supported shells.

It currently supports the following shells:

- bash
- zsh
- fish

Additional instructions are available in the command's help:

```
west help completion
```

Installing CMake packages: `west zephyr-export`

This command registers the current Zephyr installation as a CMake config package in the CMake user package registry.

In Windows, the CMake user package registry is found in `HKEY_CURRENT_USER\Software\Kitware\CMake\Packages`.

In Linux and MacOS, the CMake user package registry is found in. `~/.cmake/packages`.

You may run this command when setting up a Zephyr workspace. If you do, application CMakeLists.txt files that are outside of your workspace will be able to find the Zephyr repository with the following:

```
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

See share/zephyr-package/cmake for details.

Software bill of materials: `west spdx`

This command generates SPDX 2.3 tag-value documents, creating relationships from source files to the corresponding generated build files. `SPDX-License-Identifier` comments in source files are scanned and filled into the SPDX documents.

To use this command:

1. Pre-populate a build directory `BUILD_DIR` like this:

   ```
   west spdx --init -d BUILD_DIR
   ```

   This step ensures the build directory contains CMake metadata required for SPDX document generation.

2. Enable `CONFIG_BUILD_OUTPUT_META` in your project.

3. Build your application using this pre-created build directory, like so:

   ```
   west build -d BUILD_DIR [...]
   ```

4. Generate SPDX documents using this build directory:

   ```
   west spdx -d BUILD_DIR
   ```

This generates the following SPDX bill-of-materials (BOM) documents in `BUILD_DIR/spdx/`:

- `app.spdx`: BOM for the application source files used for the build
- `zephyr.spdx`: BOM for the specific Zephyr source code files used for the build
- `build.spdx`: BOM for the built output files
- `modules-deps.spdx`: BOM for modules dependencies. Check *modules* for more details.

Each file in the bill-of-materials is scanned, so that its hashes (SHA256 and SHA1) can be recorded, along with any detected licenses if an `SPDX-License-Identifier` comment appears in the file.

SPDX Relationships are created to indicate dependencies between CMake build targets, build targets that are linked together, and source files that are compiled to generate the built library files.

`west spdx` accepts these additional options:

- `-n PREFIX`: a prefix for the Document Namespaces that will be included in the generated SPDX documents. See SPDX specification clause 6 for details. If `-n` is omitted, a default namespace will be generated according to the default format described in section 2.5 using a random UUID.
- `-s SPDX_DIR`: specifies an alternate directory where the SPDX documents should be written instead of `BUILD_DIR/spdx/`.
- `--analyze-includes`: in addition to recording the compiled source code files (e.g. `.c`, `.S`) in the bills-of-materials, also attempt to determine the specific header files that are included for each `.c` file.

  This takes longer, as it performs a dry run using the C compiler for each `.c` file using the same arguments that were passed to it for the actual build.
- `--include-sdk`: with `--analyze-includes`, also create a fourth SPDX document, `sdk.spdx`, which lists header files included from the SDK.

Working with binary blobs: `west blobs`

The `blobs` command allows users to interact with *binary blobs* declared in one or more *modules* via their *module.yml* file.

The `blobs` command has three sub-commands, used to list, fetch or clean (i.e. delete) the binary blobs themselves.

You can list binary blobs while specifying the format of the output:

```
west blobs list -f '{module}: {type} {path}'
```

For the full set of variables available in `-f/--format` run `west blobs -h`.

Fetching blobs works in a similar manner:

```
west blobs fetch
```

Note that, as described in *the modules section*, fetched blobs are stored in a `zephyr/blobs/` folder relative to the root of the corresponding module repository.

As does deleting them:

```
west blobs clean
```

Additionally the tool allows you to specify the modules you want to list, fetch or clean blobs for by typing the module names as a command-line parameter.

Twister wrapper: `west twister`

This command is a wrapper for *twister*.

Twister can then be invoked via west as follows:

```
west twister -help
west twister -T tests/ztest/base
```

Working with binary descriptors: `west bindesc`

The `bindesc` command allows users to read *binary descriptors* of executable files. It currently supports `.bin`, `.hex`, `.elf` and `.uf2` files as input.

You can search for a specific descriptor in an image, for example:

```
west bindesc search KERNEL_VERSION_STRING build/zephyr/zephyr.bin
```

You can search for a custom descriptor by type and ID, for example:

```
west bindesc custom_search STR 0x200 build/zephyr/zephyr.bin
```

You can dump all of the descriptors in an image using:

```
west bindesc dump build/zephyr/zephyr.bin
```

You can list all known standard descriptor names using:

```
west bindesc list
```

2.11.13 History and Motivation

West was added to the Zephyr project to fulfill two fundamental requirements:

- The ability to work with multiple Git repositories
- The ability to provide an extensible and user-friendly command-line interface for basic Zephyr workflows

During the development of west, a set of *Design Constraints* were identified to avoid the common pitfalls of tools of this kind.

Requirements

Although the motivation behind splitting the Zephyr codebase into multiple repositories is outside of the scope of this page, the fundamental requirements, along with a clear justification of the choice not to use existing tools and instead develop a new one, do belong here.

The basic requirements are:

- **R1**: Keep externally maintained code in separately maintained repositories outside of the main zephyr repository, without requiring users to manually clone each of the external repositories
- **R2**: Provide a tool that both Zephyr users and distributors can make use of to benefit from and extend
- **R3**: Allow users and downstream distributions to override or remove repositories without having to make changes to the zephyr repository
- **R4**: Support both continuous tracking and commit-based (bisectable) project updating

Rationale for a custom tool

Some of west's features are similar to those provided by Git Submodules and Google's repo.

Existing tools were considered during west's initial design and development. None were found suitable for Zephyr's requirements. In particular, these were examined in detail:

- Google repo
  - Does not cleanly support using zephyr as the manifest repository (**R4**)
  - Python 2 only
  - Does not play well with Windows
  - Assumes Gerrit is used for code review

- Git submodules
  - Does not fully support **R1**, since the externally maintained repositories would still need to be inside the main zephyr Git tree
  - Does not support **R3**, since downstream copies would need to either delete or replace submodule definitions
  - Does not support continuous tracking of the latest `HEAD` in external repositories **(R4)**
  - Requires hardcoding of the paths/locations of the external repositories

Multiple Git Repositories

Zephyr intends to provide all required building blocks needed to deploy complex IoT applications. This in turn means that the Zephyr project is much more than an RTOS kernel, and is instead a collection of components that work together. In this context, there are a few reasons to work with multiple Git repositories in a standardized manner within the project:

- Clean separation of Zephyr original code and imported projects and libraries
- Avoidance of license incompatibilities between original and imported code
- Reduction in size and scope of the core Zephyr codebase, with additional repositories containing optional components instead of being imported directly into the tree
- Safety and security certifications
- Enforcement of modularization of the components
- Out-of-tree development based on subsets of the supported boards and SoCs

See *Basics* for information on how west workspaces manage multiple git repositories.

Design Constraints

West is:

- **Optional**: it is always *possible* to drop back to "raw" command-line tools, i.e. use Zephyr without using west (although west itself might need to be installed and accessible to the build system). It may not always be *convenient* to do so, however. (If all of west's features were already conveniently available, there would be no reason to develop it.)
- **Compatible with CMake**: building, flashing and debugging, and emulator support will always remain compatible with direct use of CMake.
- **Cross-platform**: West is written in Python 3, and works on all platforms supported by Zephyr.
- **Usable as a Library**: whenever possible, west features are implemented as libraries that can be used standalone in other programs, along with separate command line interfaces that wrap them. West itself is a Python package named `west`; its libraries are implemented as subpackages.
- **Conservative about features**: no features will be accepted without strong and compelling motivation.
- **Clearly specified**: West's behavior in cases where it wraps other commands is clearly specified and documented. This enables interoperability with third party tools, and means Zephyr developers can always find out what is happening "under the hood" when using west.

See Zephyr issue #6205 and for more details and discussion.

2.11.14 Moving to West

To convert a "pre-west" Zephyr setup on your computer to west, follow these steps. If you are starting from scratch, use the *Getting Started Guide* instead. See *Troubleshooting West* for advice on common issues.

1. Install west.

   On Linux:

   ```
   pip3 install --user -U west
   ```

   On Windows and macOS:

   ```
   pip3 install -U west
   ```

   For details, see *Installing west*.

2. Move your zephyr repository to a new `zephyrproject` parent directory, and change directory there.

   On Linux and macOS:

   ```
   mkdir zephyrproject
   mv zephyr zephyrproject
   cd zephyrproject
   ```

   On Windows `cmd.exe`:

   ```
   mkdir zephyrproject
   move zephyr zephyrproject
   chdir zephyrproject
   ```

   The name `zephyrproject` is recommended, but you can choose any name with no spaces anywhere in the path.

3. Create a *west workspace* using the zephyr repository as a local manifest repository:

   ```
   west init -l zephyr
   ```

   This creates `zephyrproject/.west`, marking the root of your workspace, and does some other setup. It will not change the contents of the zephyr repository in any way.

4. Clone the rest of the repositories used by zephyr:

   ```
   west update
   ```

   Make sure to run this command whenever you pull zephyr. Otherwise, your local repositories will get out of sync. (Run `west list` for current information on these repositories.)

You are done: `zephyrproject` is now set up to use west.

2.11.15 Using Zephyr without west

This page provides information on using Zephyr without west. This is not recommended for beginners due to the extra effort involved. In particular, you will have to do work "by hand" to replace these features:

- cloning the additional source code repositories used by Zephyr in addition to the main zephyr repository, and keeping them up to date
- specifying the locations of these repositories to the Zephyr build system
- flashing and debugging without understanding detailed usage of the relevant host tools

Note

If you have previously installed west and want to stop using it, uninstall it first:

```
pip3 uninstall west
```

Otherwise, Zephyr's build system will find it and may try to use it.

Getting the Source

In addition to downloading the zephyr source code repository itself, you will need to manually clone the additional projects listed in the *west manifest* file inside that repository.

```
mkdir zephyrproject
cd zephyrproject
git clone https://github.com/zephyrproject-rtos/zephyr
# clone additional repositories listed in zephyr/west.yml,
# and check out the specified revisions as well.
```

As you pull changes in the zephyr repository, you will also need to maintain those additional repositories, adding new ones as necessary and keeping existing ones up to date at the latest revisions.

Building applications

You can build a Zephyr application using CMake and Ninja (or make) directly without west installed if you specify any modules manually.

```
cmake -Bbuild -GNinja -DZEPHYR_MODULES=module1;module2;... samples/hello_world
ninja -Cbuild
```

When building with west installed, the Zephyr build system will use it to set *ZEPHYR_MODULES*.

If you don't have west installed and your application does not need any of these repositories, the build will still work.

If you don't have west installed and your application *does* need one of these repositories, you must set **ZEPHYR_MODULES** yourself as shown above.

See *Modules (External projects)* for more details.

Similarly, if your application requires binary blobs and you are not using west, you will need to download and place those blobs in the right places instead of using `west blobs`. See *Binary Blobs* for more details.

Flashing and Debugging

Running build system targets like `ninja flash`, `ninja debug`, etc. is just a call to the corresponding *west command*. For example, `ninja flash` calls `west flash`[1]. If you don't have west installed on your system, running those targets will fail. You can of course still flash and debug using any *Flash & Debug Host Tools* which work for your board (and which those west commands wrap).

[1] Note that `west build` invokes `ninja`, among other tools. There's no recursive invocation of either `west` or `ninja` involved by default, however, as `west build` does not invoke `ninja flash`, `debug`, etc. The one exception is if you specifically run one of these build system targets with a command line like `west build -t flash`. In that case, west is run twice: once for `west build`, and in a subprocess, again for `west flash`. Even in this case, `ninja` is only run once, as `ninja flash`. This is because these build system targets depend on an up to date build of the Zephyr application, so it's compiled before `west flash` is run.

If you want to use these build system targets but do not want to install west on your system using `pip`, it is possible to do so by manually creating a *west workspace*:

```
# cd into zephyrproject if not already there
git clone https://github.com/zephyrproject-rtos/west.git .west/west
```

Then create a file `.west/config` with the following contents:

```
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

After that, and in order for `ninja` to be able to invoke `west` to flash and debug, you must specify the west directory. This can be done by setting the environment variable `WEST_DIR` to point to `zephyrproject/.west/west` before running CMake to set up a build directory.

For details on west's Python APIs, see west-apis.

2.12 Testing

2.12.1 Test Framework

The Zephyr Test Framework (Ztest) provides a simple testing framework intended to be used during development. It provides basic assertion macros and a generic test structure.

The framework can be used in two ways, either as a generic framework for integration testing, or for unit testing specific modules.

Creating a test suite

Using Ztest to create a test suite is as easy as calling the *ZTEST_SUITE*. The macro accepts the following arguments:

- `suite_name` - The name of the suite. This name must be unique within a single binary.
- *ztest_suite_predicate_t* - An optional predicate function to allow choosing when the test will run. The predicate will get a pointer to the global state passed in through *ztest_run_all()* and should return a boolean to decide if the suite should run.
- *ztest_suite_setup_t* - An optional setup function which returns a test fixture. This will be called and run once per test suite run.
- *ztest_suite_before_t* - An optional before function which will run before every single test in this suite.
- *ztest_suite_after_t* - An optional after function which will run after every single test in this suite.
- *ztest_suite_teardown_t* - An optional teardown function which will run at the end of all the tests in the suite.

Below is an example of a test suite using a predicate:

```
#include <zephyr/ztest.h>
#include "test_state.h"

static bool predicate(const void *global_state)
{
```

(continues on next page)

(continued from previous page)

```
     return ((const struct test_state*)global_state)->x == 5;
}

ZTEST_SUITE(alternating_suite, predicate, NULL, NULL, NULL, NULL);
```

Adding tests to a suite

There are 4 macros used to add a test to a suite, they are:

- *ZTEST* (suite_name, test_name) - Which can be used to add a test by test_name to a given suite by suite_name.
- *ZTEST_USER* (suite_name, test_name) - Which behaves the same as *ZTEST*, only that when CONFIG_USERSPACE is enabled, then the test will be run in a userspace thread.
- *ZTEST_F* (suite_name, test_name) - Which behaves the same as *ZTEST*, only that the test function will already include a variable named fixture with the type <suite_name>_fixture.
- *ZTEST_USER_F* (suite_name, test_name) - Which combines the fixture feature of *ZTEST_F* with the userspace threading for the test.

Test fixtures Test fixtures can be used to help simplify repeated test setup operations. In many cases, tests in the same suite will require some initial setup followed by some form of reset between each test. This is achieved via fixtures in the following way:

```
#include <zephyr/ztest.h>

struct my_suite_fixture {
     size_t max_size;
     size_t size;
     uint8_t buff[1];
};

static void *my_suite_setup(void)
{
     /* Allocate the fixture with 256 byte buffer */
   struct my_suite_fixture *fixture = malloc(sizeof(struct my_suite_fixture) + 255);

     zassume_not_null(fixture, NULL);
     fixture->max_size = 256;

     return fixture;
}

static void my_suite_before(void *f)
{
     struct my_suite_fixture *fixture = (struct my_suite_fixture *)f;
     memset(fixture->buff, 0, fixture->max_size);
     fixture->size = 0;
}

static void my_suite_teardown(void *f)
{
   free(f);
}

ZTEST_SUITE(my_suite, NULL, my_suite_setup, my_suite_before, NULL, my_suite_teardown);
```

(continues on next page)

(continued from previous page)

```
ZTEST_F(my_suite, test_feature_x)
{
     zassert_equal(0, fixture->size);
     zassert_equal(256, fixture->max_size);
}
```

Using memory allocated by a test fixture in a userspace thread, such as during execution of *ZTEST_USER* or *ZTEST_USER_F*, requires that memory to be declared userspace accessible. This is because the fixture memory is owned and initialized by kernel space. The Ztest framework provides the *ZTEST_DMEM* and *ZTEST_BMEM* macros for use of such user/kernel space shared memory.

Advanced features

Test result expectations Some tests were made to be broken. In cases where the test is expected to fail or skip due to the nature of the code, it's possible to annotate the test as such. For example:

```
#include <zephyr/ztest.h>

ZTEST_SUITE(my_suite, NULL, NULL, NULL, NULL, NULL);

ZTEST_EXPECT_FAIL(my_suite, test_fail);
ZTEST(my_suite, test_fail)
{
  /** This will fail the test */
  zassert_true(false, NULL);
}

ZTEST_EXPECT_SKIP(my_suite, test_skip);
ZTEST(my_suite, test_skip)
{
  /** This will skip the test */
  zassume_true(false, NULL);
}
```

In this example, the above tests should be marked as failed and skipped respectively. Instead, Ztest will mark both as passed due to the expectation.

Test rules Test rules are a way to run the same logic for every test and every suite. There are a lot of cases where you might want to reset some state for every test in the binary (regardless of which suite is currently running). As an example, this could be to reset mocks, reset emulators, flush the UART, etc.:

```
#include <zephyr/fff.h>
#include <zephyr/ztest.h>

#include "test_mocks.h"

DEFINE_FFF_GLOBALS;

DEFINE_FAKE_VOID_FUN(my_weak_func);

static void fff_reset_rule_before(const struct ztest_unit_test *test, void *fixture)
{
     ARG_UNUSED(test);
     ARG_UNUSED(fixture);

     RESET_FAKE(my_weak_func);
```

(continues on next page)

(continued from previous page)

```
}

ZTEST_RULE(fff_reset_rule, fff_reset_rule_before, NULL);
```

A custom `test_main` While the Ztest framework provides a default `test_main()` function, it's possible that some applications will want to provide custom behavior. This is particularly true if there's some global state that the tests depend on and that state either cannot be replicated or is difficult to replicate without starting the process over. For example, one such state could be a power sequence. Assuming there's a board with several steps in the power-on sequence a test suite can be written using the `predicate` to control when it would run. In that case, the `test_main()` function can be written as follows:

```
#include <zephyr/ztest.h>

#include "my_test.h"

void test_main(void)
{
     struct power_sequence_state state;

     /* Only suites that use a predicate checking for phase == PWR_PHASE_0 will run. */
     state.phase = PWR_PHASE_0;
     ztest_run_all(&state, false, 1, 1);

     /* Only suites that use a predicate checking for phase == PWR_PHASE_1 will run. */
     state.phase = PWR_PHASE_1;
     ztest_run_all(&state, false, 1, 1);

     /* Only suites that use a predicate checking for phase == PWR_PHASE_2 will run. */
     state.phase = PWR_PHASE_2;
     ztest_run_all(&state, false, 1, 1);

     /* Check that all the suites in this binary ran at least once. */
     ztest_verify_all_test_suites_ran();
}
```

Quick start - Integration testing

A simple working base is located at samples/subsys/testsuite/integration. To make a test application for the **bar** component of **foo**, you should copy the sample folder to `tests/foo/bar` and edit files there adjusting for your test application's purposes.

To build and execute all applicable test scenarios defined in your test application use the *Twister* tool, for example:

```
./scripts/twister -T tests/foo/bar/
```

To select just one of the test scenarios, run Twister with `--scenario` command:

```
./scripts/twister --scenario tests/foo/bar/your.test.scenario.name
```

In the command line above `tests/foo/bar` is the path to your test application and `your.test.scenario.name` references a test scenario defined in `testcase.yaml` file, which is like `sample.testing.ztest` in the boilerplate test suite sample.

See *Twister test project diagram* for more details on how Twister deals with Ztest application.

The sample contains the following files:

CMakeLists.txt

```
# SPDX-License-Identifier: Apache-2.0

cmake_minimum_required(VERSION 3.20.0)
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
project(integration)

FILE(GLOB app_sources src/*.c)
target_sources(app PRIVATE ${app_sources})
```

testcase.yaml

```
tests:
  # section.subsection
  sample.testing.ztest:
    build_only: true
    platform_allow:
      - native_posix
      - native_sim
    integration_platforms:
      - native_sim
    tags: test_framework
```

prj.conf

```
CONFIG_ZTEST=y
```

src/main.c (see *best practices*)

```
/*
 * Copyright (c) 2016 Intel Corporation
 *
 * SPDX-License-Identifier: Apache-2.0
 */

#include <zephyr/ztest.h>

ZTEST_SUITE(framework_tests, NULL, NULL, NULL, NULL, NULL);

/**
 * @brief Test Asserts
 *
 * This test verifies various assert macros provided by ztest.
 *
 */
ZTEST(framework_tests, test_assert)
{
        zassert_true(1, "1 was false");
        zassert_false(0, "0 was true");
        zassert_is_null(NULL, "NULL was not NULL");
        zassert_not_null("foo", "\"foo\" was NULL");
        zassert_equal(1, 1, "1 was not equal to 1");
        zassert_equal_ptr(NULL, NULL, "NULL was not equal to NULL");
}
```

- *Listing Tests*
- *Skipping Tests*

A test application may consist of multiple test suites that either can be testing functionality or APIs. Functions implementing a test case should follow the guidelines below:

- Test cases function names should be prefixed with **test_**
- Test cases should be documented using doxygen
- Test case function names should be unique within the section or component being tested

For example:

```
/**
 * @brief Test Asserts
 *
 * This test case verifies the zassert_true macro.
 */
ZTEST(my_suite, test_assert)
{
        zassert_true(1, "1 was false");
}
```

Listing Tests Tests (test applications) in the Zephyr tree consist of many test scenarios that run as part of a project and test similar functionality, for example an API or a feature. The `twister` script can parse the test scenarios, suites and cases in all test applications or a subset of them, and can generate reports on a granular level, i.e. if test cases have passed or failed or if they were blocked or skipped.

Twister parses the source files looking for test case names, so you can list all kernel test cases, for example, by running:

```
./scripts/twister --list-tests -T tests/kernel
```

Skipping Tests Special- or architecture-specific tests cannot run on all platforms and architectures, however we still want to count those and report them as being skipped. Because the test inventory and the list of tests is extracted from the code, adding conditionals inside the test suite is sub-optimal. Tests that need to be skipped for a certain platform or feature need to explicitly report a skip using *ztest_test_skip()* or `Z_TEST_SKIP_IFDEF`. If the test runs, it needs to report either a pass or fail. For example:

```
#ifdef CONFIG_TEST1
ZTEST(common, test_test1)
{
     zassert_true(1, "true");
}
#else
ZTEST(common, test_test1)
{
     ztest_test_skip();
}
#endif

ZTEST(common, test_test2)
{
     Z_TEST_SKIP_IFDEF(CONFIG_BUGxxxxx);
     zassert_equal(1, 0, NULL);
}

ZTEST_SUITE(common, NULL, NULL, NULL, NULL, NULL);
```

Quick start - Unit testing

Ztest can be used for unit testing. This means that rather than including the entire Zephyr OS for testing a single function, you can focus the testing efforts into the specific module in question. This will speed up testing since only the module will have to be compiled in, and the tested functions will be called directly.

Examples of unit tests can be found in the tests/unit/ folder. In order to declare the unit tests present in a source folder, you need to add the relevant source files to the `testbinary` target from the CMake unittest component. See a minimal example below:

```
cmake_minimum_required(VERSION 3.20.0)

project(app)
find_package(Zephyr COMPONENTS unittest REQUIRED HINTS $ENV{ZEPHYR_BASE})
target_sources(testbinary PRIVATE main.c)
```

Since you won't be including basic kernel data structures that most code depends on, you have to provide function stubs in the test. Ztest provides some helpers for mocking functions, as demonstrated below.

In a unit test, mock objects can simulate the behavior of complex real objects and are used to decide whether a test failed or passed by verifying whether an interaction with an object occurred, and if required, to assert the order of that interaction.

Best practices for declaring the test suite

twister and other validation tools need to obtain the list of test cases that a Zephyr *ztest* test image will expose.

Rationale

This all is for the purpose of traceability. It's not enough to have only a semaphore test application. We also need to show that we have testpoints for all APIs and functionality, and we trace back to documentation of the API, and functional requirements.

The idea is that test reports show results for every test case as passed, failed, blocked, or skipped. Reporting on only the high-level test application, particularly when tests do too many things, is too vague.

Other questions:

- Why not pre-scan with CPP and then parse? or post scan the ELF file?

  If C pre-processing or building fails because of any issue, then we won't be able to tell the subcases.

- Why not declare them in the YAML test configuration?

  A separate test case description file would be harder to maintain than just keeping the information in the test source files themselves – only one file to update when changes are made eliminates duplication.

Stress test framework

Zephyr stress test framework (Ztress) provides an environment for executing user functions in multiple priority contexts. It can be used to validate that code is resilient to preemptions. The framework tracks the number of executions and preemptions for each context. Execution can

have various completion conditions like timeout, number of executions or number of preemptions.

The framework is setting up the environment by creating the requested number of threads (each on different priority), optionally starting a timer. For each context, a user function (different for each context) is called and then the context sleeps for a randomized amount of system ticks. The framework is tracking CPU load and adjusts sleeping periods to achieve higher CPU load. In order to increase the probability of preemptions, the system clock frequency should be relatively high. The default 100 Hz on QEMU x86 is much too low and it is recommended to increase it to 100 kHz.

The stress test environment is setup and executed using *ZTRESS_EXECUTE* which accepts a variable number of arguments. Each argument is a context that is specified by *ZTRESS_TIMER* or *ZTRESS_THREAD* macros. Contexts are specified in priority descending order. Each context specifies completion conditions by providing the minimum number of executions and preemptions. When all conditions are met and the execution has completed, an execution report is printed and the macro returns. Note that while the test is executing, a progress report is periodically printed.

Execution can be prematurely completed by specifying a test timeout (*ztress_set_timeout()*) or an explicit abort (*ztress_abort()*).

User function parameters contains an execution counter and a flag indicating if it is the last execution.

The example below presents how to setup and run 3 contexts (one of which is k_timer interrupt handler context). Completion criteria is set to at least 10000 executions of each context and 1000 preemptions of the lowest priority context. Additionally, the timeout is configured to complete after 10 seconds if those conditions are not met. The last argument of each context is the initial sleep time which will be adjusted throughout the test to achieve the highest CPU load.

```
ztress_set_timeout(K_MSEC(10000));
ZTRESS_EXECUTE(ZTRESS_TIMER(foo_0, user_data_0, 10000, Z_TIMEOUT_TICKS(20)),
               ZTRESS_THREAD(foo_1, user_data_1, 10000, 0, Z_TIMEOUT_TICKS(20)),
               ZTRESS_THREAD(foo_2, user_data_2, 10000, 1000, Z_TIMEOUT_
↪TICKS(20)));
```

Configuration Static configuration of Ztress contains:

- CONFIG_ZTRESS_MAX_THREADS - number of supported threads.
- CONFIG_ZTRESS_STACK_SIZE - Stack size of created threads.
- CONFIG_ZTRESS_REPORT_PROGRESS_MS - Test progress report interval.

API reference

Running tests

group **ztest_test**

This module eases the testing process by providing helpful macros and other testing structures.

Defines

ZTEST_EXPECT_FAIL(_suite_name, _test_name)

Expect a test to fail (mark it passing if it failed)

Adding this macro to your logic will allow the failing test to be considered passing, example:

```
ZTEST_EXPECT_FAIL(my_suite, test_x);
ZTEST(my_suite, text_x) {
  zassert_true(false, NULL);
}
```

Parameters

- **_suite_name** – The name of the suite
- **_test_name** – The name of the test

ZTEST_EXPECT_SKIP(_suite_name, _test_name)

Expect a test to skip (mark it passing if it failed)

Adding this macro to your logic will allow the failing test to be considered passing, example:

```
ZTEST_EXPECT_SKIP(my_suite, test_x);
ZTEST(my_suite, text_x) {
  zassume_true(false, NULL);
}
```

Parameters

- **_suite_name** – The name of the suite
- **_test_name** – The name of the test

ZTEST_TEST_COUNT

Number of registered unit tests.

ZTEST_SUITE_COUNT

Number of registered test suites.

ZTEST_SUITE(SUITE_NAME, PREDICATE, setup_fn, before_fn, after_fn, teardown_fn)

Create and register a ztest suite.

Using this macro creates a new test suite. It then creates a struct *ztest_suite_node* in a specific linker section.

Tests can then be run by calling ztest_run_test_suites(const void *state) by passing in the current state. See the documentation for ztest_run_test_suites for more info.

Parameters

- **SUITE_NAME** – The name of the suite
- **PREDICATE** – A function to test against the state and determine if the test should run.
- **setup_fn** – The setup function to call before running this test suite
- **before_fn** – The function to call before each unit test in this suite
- **after_fn** – The function to call after each unit test in this suite
- **teardown_fn** – The function to call after running all the tests in this suite

ZTEST_DMEM

Make data section used by Ztest userspace accessible.

ZTEST_BMEM
: Make bss section used by Ztest userspace accessible.

ZTEST_SECTION
: Ztest data section for accessing data from userspace.

ZTEST(suite, fn)
: Create and register a new unit test.

  Calling this macro will create a new unit test and attach it to the declared `suite`. The `suite` does not need to be defined in the same compilation unit.

  Parameters

  - **suite** – The name of the test suite to attach this test
  - **fn** – The test function to call.

ZTEST_USER(suite, fn)
: Define a test function that should run as a user thread.

  This macro behaves exactly the same as ZTEST, but calls the test function in user space if `CONFIG_USERSPACE` was enabled.

  Parameters

  - **suite** – The name of the test suite to attach this test
  - **fn** – The test function to call.

ZTEST_F(suite, fn)
: Define a test function.

  This macro behaves exactly the same as *ZTEST()*, but the function takes an argument for the fixture of type `struct suite##_fixture*` named `fixture`.

  Parameters

  - **suite** – The name of the test suite to attach this test
  - **fn** – The test function to call.

ZTEST_USER_F(suite, fn)
: Define a test function that should run as a user thread.

  If CONFIG_USERSPACE is not enabled, this is functionally identical to *ZTEST_F()*. The test function takes a single fixture argument of type `struct suite##_fixture*` named `fixture`.

  Parameters

  - **suite** – The name of the test suite to attach this test
  - **fn** – The test function to call.

ZTEST_RULE(name, before_each_fn, after_each_fn)
: Define a test rule that will run before/after each unit test.

  Functions defined here will run before/after each unit test for every test suite. Along with the callback, the test functions are provided a pointer to the test being run, and the data. This provides a mechanism for tests to perform custom operations depending on the specific test or the data (for example logging may use the test's name).

  Ordering:

  - Test rule's `before` function will run before the suite's `before` function. This is done to allow the test suite's customization to take precedence over the rule which is applied to all suites.

- Test rule's `after` function is not guaranteed to run in any particular order.

Parameters

- **name** – The name for the test rule (must be unique within the compilation unit)
- **before_each_fn** – The callback function (ztest_rule_cb) to call before each test (may be NULL)
- **after_each_fn** – The callback function (ztest_rule_cb) to call after each test (may be NULL)

ztest_run_test_suite(suite, shuffle, suite_iter, case_iter)

Run the specified test suite.

Parameters

- **suite** – Test suite to run.
- **shuffle** – Shuffle tests
- **suite_iter** – Test suite repetitions.
- **case_iter** – Test case repetitions.

Typedefs

typedef void *(***ztest_suite_setup_t**)(void)

Setup function to run before running this suite.

Return
Pointer to the data structure that will be used throughout this test suite

typedef void (***ztest_suite_before_t**)(void *fixture)

Function to run before each test in this suite.

Param fixture
The test suite's fixture returned from setup()

typedef void (***ztest_suite_after_t**)(void *fixture)

Function to run after each test in this suite.

Param fixture
The test suite's fixture returned from setup()

typedef void (***ztest_suite_teardown_t**)(void *fixture)

Teardown function to run after running this suite.

Param fixture
The test suite's data returned from setup()

typedef bool (***ztest_suite_predicate_t**)(const void *global_state)

An optional predicate function to determine if the test should run.

If NULL, then the test will only run once on the first attempt.

Param global_state
The current state of the test application.

Return
True if the suite should be run; false to skip.

typedef void (*`ztest_rule_cb`)(const struct *ztest_unit_test* *test, void *data)

Test rule callback function signature.

The function signature that can be used to register a test rule's before/after callback. This provides access to the test and the fixture data (if provided).

Param test
Pointer to the unit test in context

Param data
Pointer to the test's fixture data (may be NULL)

Enums

enum `ztest_expected_result`

The expected result of a test.

See also

ZTEST_EXPECT_FAIL

See also

ZTEST_EXPECT_SKIP

Values:

enumerator `ZTEST_EXPECTED_RESULT_FAIL` = 0

Expect a test to fail.

enumerator `ZTEST_EXPECTED_RESULT_SKIP`

Expect a test to pass.

enum `ztest_result`

The result of the current running test.

It's possible that the setup function sets the result to ZTEST_RESULT_SUITE_* which will apply the failure/skip to every test in the suite.

Values:

enumerator `ZTEST_RESULT_PENDING`

enumerator `ZTEST_RESULT_PASS`

enumerator `ZTEST_RESULT_FAIL`

enumerator ZTEST_RESULT_SKIP

enumerator ZTEST_RESULT_SUITE_SKIP

enumerator ZTEST_RESULT_SUITE_FAIL

enum ztest_phase

Each enum member represents a distinct phase of execution for the test binary.

TEST_PHASE_FRAMEWORK is active when internal ztest code is executing; the rest refer to corresponding phases of user test code.

Values:

enumerator TEST_PHASE_SETUP

enumerator TEST_PHASE_BEFORE

enumerator TEST_PHASE_TEST

enumerator TEST_PHASE_AFTER

enumerator TEST_PHASE_TEARDOWN

enumerator TEST_PHASE_FRAMEWORK

Functions

void ztest_run_all(const void *state, bool shuffle, int suite_iter, int case_iter)

Default entry point for running or listing registered unit tests.

Parameters

- state – The current state of the machine as it relates to the test executable.
- shuffle – Shuffle tests
- suite_iter – Test suite repetitions.
- case_iter – Test case repetitions.

int ztest_run_test_suites(const void *state, bool shuffle, int suite_iter, int case_iter)

Run the registered unit tests which return true from their predicate function.

Parameters

- state – The current state of the machine as it relates to the test executable.
- shuffle – Shuffle tests
- suite_iter – Test suite repetitions.
- case_iter – Test case repetitions.

Returns

The number of tests that ran.

void **ztest_verify_all_test_suites_ran**(void)

Fails the test if any of the registered tests did not run.

When registering test suites, a pragma function can be provided to determine WHEN the test should run. It is possible that a test suite could be registered but the pragma always prevents it from running. In cases where a test should make sure that ALL suites ran at least once, this function may be called at the end of test_main(). It will cause the test to fail if any suite was registered but never ran.

void **ztest_test_fail**(void)

Fail the currently running test.

This is the function called from failed assertions and the like. You probably don't need to call it yourself.

void **ztest_test_pass**(void)

Pass the currently running test.

Normally a test passes just by returning without an assertion failure. However, if the success case for your test involves a fatal fault, you can call this function from k_sys_fatal_error_handler to indicate that the test passed before aborting the thread.

void **ztest_test_skip**(void)

Skip the current test.

void **ztest_skip_failed_assumption**(void)

void **ztest_simple_1cpu_before**(void *data)

A 'before' function to use in test suites that just need to start 1cpu.

Ignores data, and calls z_test_1cpu_start()

Parameters

- **data** – The test suite's data

void **ztest_simple_1cpu_after**(void *data)

A 'after' function to use in test suites that just need to stop 1cpu.

Ignores data, and calls z_test_1cpu_stop()

Parameters

- **data** – The test suite's data

Variables

struct *k_mem_partition* **ztest_mem_partition**

struct **ztest_expected_result_entry**

#include <ztest_test.h> A single expectation entry allowing tests to fail/skip and be considered passing.

See also

ZTEST_EXPECT_FAIL

See also

ZTEST_EXPECT_SKIP

Public Members

const char *`test_suite_name`
The test suite's name for the expectation.

const char *`test_name`
The test's name for the expectation.

enum *ztest_expected_result* `expected_result`
The expectation.

struct `ztest_unit_test`
#include <ztest_test.h>

Public Members

struct *ztest_unit_test_stats* *const `stats`
Stats.

struct `ztest_suite_stats`
#include <ztest_test.h> Stats about a ztest suite.

Public Members

uint32_t `run_count`
The number of times that the suite ran.

uint32_t `skip_count`
The number of times that the suite was skipped.

uint32_t `fail_count`
The number of times that the suite failed.

struct `ztest_unit_test_stats`
#include <ztest_test.h>

Public Members

uint32_t `run_count`
The number of times that the test ran.

uint32_t **skip_count**
The number of times that the test was skipped.

uint32_t **fail_count**
The number of times that the test failed.

uint32_t **pass_count**
The number of times that the test passed.

uint32_t **duration_worst_ms**
The longest duration of the test across multiple times.

struct **ztest_suite_node**
#include <ztest_test.h> A single node of test suite.

Each node should be added to a single linker section which will allow *ztest_run_test_suites()* to iterate over the various nodes.

Public Members

const char *const **name**
The name of the test suite.

const *ztest_suite_setup_t* **setup**
Setup function.

const *ztest_suite_before_t* **before**
Before function.

const *ztest_suite_after_t* **after**
After function.

const *ztest_suite_teardown_t* **teardown**
Teardown function.

const *ztest_suite_predicate_t* **predicate**
Optional predicate filter.

struct *ztest_suite_stats* *const **stats**
Stats.

struct **ztest_test_rule**

struct **ztest_arch_api**
#include <ztest_test.h> Structure for architecture specific APIs.

Assertions These macros will instantly fail the test if the related assertion fails. When an assertion fails, it will print the current file, line and function, alongside a reason for the failure and an optional message. If the config `CONFIG_ZTEST_ASSERT_VERBOSE` is 0, the assertions will only print the file and line numbers, reducing the binary size of the test.

Example output for a failed macro from `zassert_equal(buf->ref, 2, "Invalid refcount")`:

```
Assertion failed at main.c:62: test_get_single_buffer: Invalid refcount (buf->ref not equal␣
↪to 2)
Aborted at unit test function
```

group **ztest_assert**

This module provides assertions when using Ztest.

Defines

zassert(cond, default_msg, ...)

zassume(cond, default_msg, ...)

zexpect(cond, default_msg, ...)

zassert_unreachable(...)

Assert that this function call won't be reached.

Parameters

- **...** – Optional message and variables to print if the assertion fails

zassert_true(cond, ...)

Assert that *cond* is true.

Parameters

- **cond** – Condition to check
- **...** – Optional message and variables to print if the assertion fails

zassert_false(cond, ...)

Assert that *cond* is false.

Parameters

- **cond** – Condition to check
- **...** – Optional message and variables to print if the assertion fails

zassert_ok(cond, ...)

Assert that *cond* is 0 (success)

Parameters

- **cond** – Condition to check
- **...** – Optional message and variables to print if the assertion fails

zassert_not_ok(cond, ...)

Assert that *cond* is not 0 (failure)

Parameters

- **cond** – Condition to check
- **...** – Optional message and variables to print if the assertion fails

`zassert_is_null`(ptr, ...)
Assert that *ptr* is NULL.

Parameters

- `ptr` – Pointer to compare
- `...` – Optional message and variables to print if the assertion fails

`zassert_not_null`(ptr, ...)
Assert that *ptr* is not NULL.

Parameters

- `ptr` – Pointer to compare
- `...` – Optional message and variables to print if the assertion fails

`zassert_equal`(a, b, ...)
Assert that *a* equals *b*.

a and *b* won't be converted and will be compared directly.

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `...` – Optional message and variables to print if the assertion fails

`zassert_not_equal`(a, b, ...)
Assert that *a* does not equal *b*.

a and *b* won't be converted and will be compared directly.

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `...` – Optional message and variables to print if the assertion fails

`zassert_equal_ptr`(a, b, ...)
Assert that *a* equals *b*.

a and *b* will be converted to `void *` before comparing.

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `...` – Optional message and variables to print if the assertion fails

`zassert_within`(a, b, d, ...)
Assert that *a* is within *b* with delta *d*.

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `d` – Delta
- `...` – Optional message and variables to print if the assertion fails

`zassert_between_inclusive`(a, l, u, ...)

Assert that *a* is greater than or equal to *l* and less than or equal to *u*.

Parameters

- `a` – Value to compare
- `l` – Lower limit
- `u` – Upper limit
- `...` – Optional message and variables to print if the assertion fails

`zassert_mem_equal`(...)

Assert that 2 memory buffers have the same contents.

This macro calls the final memory comparison assertion macro. Using double expansion allows providing some arguments by macros that would expand to more than one values (ANSI-C99 defines that all the macro arguments have to be expanded before macro call).

Parameters

- `...` – Arguments, see *zassert_mem_equal__* for real arguments accepted.

`zassert_mem_equal__`(buf, exp, size, ...)

Internal assert that 2 memory buffers have the same contents.

> **Note**
>
> This is internal macro, to be used as a second expansion. See *zassert_mem_equal*.

Parameters

- `buf` – Buffer to compare
- `exp` – Buffer with expected contents
- `size` – Size of buffers
- `...` – Optional message and variables to print if the assertion fails

`zassert_str_equal`(s1, s2, ...)

Assert that 2 strings have the same contents.

Parameters

- `s1` – The first string
- `s2` – The second string
- `...` – Optional message and variables to print if the expectation fails

Expectations These macros will continue test execution if the related expectation fails and subsequently fail the test at the end of its execution. When an expectation fails, it will print the current file, line, and function, alongside a reason for the failure and an optional message but continue executing the test. If the config `CONFIG_ZTEST_ASSERT_VERBOSE` is 0, the expectations will only print the file and line numbers, reducing the binary size of the test.

For example, if the following expectations fail:

```
zexpect_equal(buf->ref, 2, "Invalid refcount");
zexpect_equal(buf->ref, 1337, "Invalid refcount");
```

The output will look something like:

```
START - test_get_single_buffer
    Expectation failed at main.c:62: test_get_single_buffer: Invalid refcount (buf->ref not␣
↪equal to 2)
    Expectation failed at main.c:63: test_get_single_buffer: Invalid refcount (buf->ref not␣
↪equal to 1337)
 FAIL - test_get_single_buffer in 0.0 seconds
```

group `ztest_expect`

This module provides expectations when using Ztest.

Defines

`zexpect_true`(cond, ...)

Expect that *cond* is true, otherwise mark test as failed but continue its execution.

Parameters

- `cond` – Condition to check
- `...` – Optional message and variables to print if the expectation fails

`zexpect_false`(cond, ...)

Expect that *cond* is false, otherwise mark test as failed but continue its execution.

Parameters

- `cond` – Condition to check
- `...` – Optional message and variables to print if the expectation fails

`zexpect_ok`(cond, ...)

Expect that *cond* is 0 (success), otherwise mark test as failed but continue its execution.

Parameters

- `cond` – Condition to check
- `...` – Optional message and variables to print if the expectation fails

`zexpect_not_ok`(cond, ...)

Expect that *cond* is not 0 (failure), otherwise mark test as failed but continue its execution.

Parameters

- `cond` – Condition to check
- `...` – Optional message and variables to print if the expectation fails

`zexpect_is_null`(ptr, ...)

Expect that *ptr* is NULL, otherwise mark test as failed but continue its execution.

Parameters

- `ptr` – Pointer to compare
- `...` – Optional message and variables to print if the expectation fails

`zexpect_not_null`(ptr, ...)

Expect that *ptr* is not NULL, otherwise mark test as failed but continue its execution.

Parameters

- `ptr` – Pointer to compare
- `...` – Optional message and variables to print if the expectation fails

`zexpect_equal`(a, b, ...)

Expect that *a* equals *b*, otherwise mark test as failed but continue its execution.

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `...` – Optional message and variables to print if the expectation fails

`zexpect_not_equal`(a, b, ...)

Expect that *a* does not equal *b*, otherwise mark test as failed but continue its execution.

a and *b* won't be converted and will be compared directly.

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `...` – Optional message and variables to print if the expectation fails

`zexpect_equal_ptr`(a, b, ...)

Expect that *a* equals *b*, otherwise mark test as failed but continue its execution.

a and *b* will be converted to `void *` before comparing.

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `...` – Optional message and variables to print if the expectation fails

`zexpect_within`(a, b, delta, ...)

Expect that *a* is within *b* with delta *d*, otherwise mark test as failed but continue its execution.

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `delta` – Difference between a and b
- `...` – Optional message and variables to print if the expectation fails

`zexpect_between_inclusive`(a, lower, upper, ...)

Expect that *a* is greater than or equal to *l* and less than or equal to *u*, otherwise mark test as failed but continue its execution.

Parameters

- `a` – Value to compare
- `lower` – Lower limit
- `upper` – Upper limit
- `...` – Optional message and variables to print if the expectation fails

`zexpect_mem_equal`(buf, exp, size, ...)

Expect that 2 memory buffers have the same contents, otherwise mark test as failed but continue its execution.

Parameters

- `buf` – Buffer to compare

- **exp** – Buffer with expected contents
- **size** – Size of buffers
- **...** – Optional message and variables to print if the expectation fails

zexpect_str_equal(s1, s2, ...)

Expect that 2 strings have the same contents, otherwise mark test as failed but continue its execution.

Parameters

- **s1** – The first string
- **s2** – The second string
- **...** – Optional message and variables to print if the expectation fails

Assumptions These macros will instantly skip the test or suite if the related assumption fails. When an assumption fails, it will print the current file, line, and function, alongside a reason for the failure and an optional message. If the config `CONFIG_ZTEST_ASSERT_VERBOSE` is 0, the assumptions will only print the file and line numbers, reducing the binary size of the test.

Example output for a failed macro from `zassume_equal(buf->ref, 2, "Invalid refcount")`:

group **ztest_assume**

This module provides assumptions when using Ztest.

Defines

zassume_true(cond, ...)

Assume that *cond* is true.

If the assumption fails, the test will be marked as "skipped".

Parameters

- **cond** – Condition to check
- **...** – Optional message and variables to print if the assumption fails

zassume_false(cond, ...)

Assume that *cond* is false.

If the assumption fails, the test will be marked as "skipped".

Parameters

- **cond** – Condition to check
- **...** – Optional message and variables to print if the assumption fails

zassume_ok(cond, ...)

Assume that *cond* is 0 (success)

If the assumption fails, the test will be marked as "skipped".

Parameters

- **cond** – Condition to check
- **...** – Optional message and variables to print if the assumption fails

`zassume_not_ok`(cond, ...)

Assume that *cond* is not 0 (failure)

If the assumption fails, the test will be marked as "skipped".

Parameters

- `cond` – Condition to check
- `...` – Optional message and variables to print if the assumption fails

`zassume_is_null`(ptr, ...)

Assume that *ptr* is NULL.

If the assumption fails, the test will be marked as "skipped".

Parameters

- `ptr` – Pointer to compare
- `...` – Optional message and variables to print if the assumption fails

`zassume_not_null`(ptr, ...)

Assume that *ptr* is not NULL.

If the assumption fails, the test will be marked as "skipped".

Parameters

- `ptr` – Pointer to compare
- `...` – Optional message and variables to print if the assumption fails

`zassume_equal`(a, b, ...)

Assume that *a* equals *b*.

a and *b* won't be converted and will be compared directly. If the assumption fails, the test will be marked as "skipped".

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `...` – Optional message and variables to print if the assumption fails

`zassume_not_equal`(a, b, ...)

Assume that *a* does not equal *b*.

a and *b* won't be converted and will be compared directly. If the assumption fails, the test will be marked as "skipped".

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `...` – Optional message and variables to print if the assumption fails

`zassume_equal_ptr`(a, b, ...)

Assume that *a* equals *b*.

a and *b* will be converted to `void *` before comparing. If the assumption fails, the test will be marked as "skipped".

Parameters

- `a` – Value to compare
- `b` – Value to compare

- `...` – Optional message and variables to print if the assumption fails

`zassume_within`(a, b, d, ...)

Assume that *a* is within *b* with delta *d*.

If the assumption fails, the test will be marked as "skipped".

Parameters

- `a` – Value to compare
- `b` – Value to compare
- `d` – Delta
- `...` – Optional message and variables to print if the assumption fails

`zassume_between_inclusive`(a, l, u, ...)

Assume that *a* is greater than or equal to *l* and less than or equal to *u*.

If the assumption fails, the test will be marked as "skipped".

Parameters

- `a` – Value to compare
- `l` – Lower limit
- `u` – Upper limit
- `...` – Optional message and variables to print if the assumption fails

`zassume_mem_equal`(...)

Assume that 2 memory buffers have the same contents.

This macro calls the final memory comparison assumption macro. Using double expansion allows providing some arguments by macros that would expand to more than one values (ANSI-C99 defines that all the macro arguments have to be expanded before macro call).

Parameters

- `...` – Arguments, see *zassume_mem_equal__* for real arguments accepted.

`zassume_mem_equal__`(buf, exp, size, ...)

Internal assume that 2 memory buffers have the same contents.

If the assumption fails, the test will be marked as "skipped".

> **Note**
>
> This is internal macro, to be used as a second expansion. See *zassume_mem_equal*.

Parameters

- `buf` – Buffer to compare
- `exp` – Buffer with expected contents
- `size` – Size of buffers
- `...` – Optional message and variables to print if the assumption fails

`zassume_str_equal`(s1, s2, ...)

Assumes that 2 strings have the same contents.

Parameters

- `s1` – The first string

- `s2` – The second string
- `...` – Optional message and variables to print if the expectation fails

Ztress

group `ztest_ztress`

This module provides test stress when using Ztest.

Defines

`ZTRESS_TIMER`(handler, user_data, exec_cnt, init_timeout)

Descriptor of a k_timer handler execution context.

The handler is executed in the k_timer handler context which typically means interrupt context. This context will preempt any other used in the set.

> **Note**
>
> There can only be up to one k_timer context in the set and it must be the first argument of *ZTRESS_EXECUTE*.

Parameters

- `handler` – User handler of type *ztress_handler*.
- `user_data` – User data passed to the `handler`.
- `exec_cnt` – Number of handler executions to complete the test. If 0 then this is not included in completion criteria.
- `init_timeout` – Initial backoff time base (given in *k_timeout_t*). It is adjusted during the test to optimize CPU load. The actual timeout used for the timer is randomized.

`ZTRESS_THREAD`(handler, user_data, exec_cnt, preempt_cnt, init_timeout)

Descriptor of a thread execution context.

The handler is executed in the thread context. The priority of the thread is determined based on the order in which contexts are listed in *ZTRESS_EXECUTE*.

> **Note**
>
> thread sleeps for random amount of time. Additionally, the thread busy-waits for a random length of time to further increase randomization in the test.

Parameters

- `handler` – User handler of type *ztress_handler*.
- `user_data` – User data passed to the `handler`.
- `exec_cnt` – Number of handler executions to complete the test. If 0 then this is not included in completion criteria.
- `preempt_cnt` – Number of preemptions of that context to complete the test. If 0 then this is not included in completion criteria.

- **init_timeout** – Initial backoff time base (given in *k_timeout_t*). It is adjusted during the test to optimize CPU load. The actual timeout used for sleeping is randomized.

ZTRESS_CONTEXT_INITIALIZER(_handler, _user_data, _exec_cnt, _preempt_cnt, _t)

Initialize context structure.

For argument types see *ztress_context_data*. For more details see *ZTRESS_THREAD*.

Parameters

- **_handler** – Handler.
- **_user_data** – User data passed to the handler.
- **_exec_cnt** – Execution count limit.
- **_preempt_cnt** – Preemption count limit.
- **_t** – Initial timeout.

ZTRESS_EXECUTE(...)

Setup and run stress test.

It initialises all contexts and calls *ztress_execute*.

Parameters

- ... – List of contexts. Contexts are configured using *ZTRESS_TIMER* and *ZTRESS_THREAD* macros. *ZTRESS_TIMER* must be the first argument if used. Each thread context has an assigned priority. The priority is assigned in a descending order (first listed thread context has the highest priority). The maximum number of supported thread contexts, including the timer context, is configurable in Kconfig (ZTRESS_MAX_THREADS).

Typedefs

typedef bool (*ztress_handler)(void *user_data, uint32_t cnt, bool last, int prio)

User handler called in one of the configured contexts.

Param user_data
User data provided in the context descriptor.

Param cnt
Current execution counter. Counted from 0.

Param last
Flag set to true indicates that it is the last execution because completion criteria are met, test timed out or was aborted.

Param prio
Context priority counting from 0 which indicates the highest priority.

Retval true
continue test.

Retval false
stop executing the current context.

Functions

int **ztress_execute**(struct *ztress_context_data* *timer_data, struct *ztress_context_data* *thread_data, size_t cnt)

Execute contexts.

The test runs until all completion requirements are met or until the test times out (use *ztress_set_timeout* to configure timeout) or until the test is aborted (*ztress_abort*).

on test completion a report is printed (*ztress_report* is called internally).

Parameters

- **timer_data** – Timer context. NULL if timer context is not used.
- **thread_data** – List of thread contexts descriptors in priority descending order.
- **cnt** – Number of thread contexts.

Return values

- **-EINVAL** – If configuration is invalid.
- **0** – if test is successfully performed.

void **ztress_abort**(void)

Abort ongoing stress test.

void **ztress_set_timeout**(*k_timeout_t* t)

Set test timeout.

Test is terminated after timeout disregarding completion criteria. Setting is persistent between executions.

Parameters

- **t** – Timeout.

void **ztress_report**(void)

Print last test report.

Report contains number of executions and preemptions for each context, initial and adjusted timeouts and CPU load during the test.

int **ztress_exec_count**(uint32_t id)

Get number of executions of a given context in the last test.

Parameters

- **id** – Context id. 0 means the highest priority.

Returns

Number of executions.

int **ztress_preempt_count**(uint32_t id)

Get number of preemptions of a given context in the last test.

Parameters

- **id** – Context id. 0 means the highest priority.

Returns

Number of preemptions.

uint32_t **ztress_optimized_ticks**(uint32_t id)

Get optimized timeout base of a given context in the last test.

Optimized value can be used to update initial value. It will improve the test since optimal CPU load will be reach immediately.

Parameters

- **id** – Context id. 0 means the highest priority.

Returns
Optimized timeout base.

struct **ztress_context_data**
#include <ztress.h>

Mocking via FFF Zephyr has integrated with FFF for mocking. See FFF for documentation. To use it, include the relevant header:

```
#include <zephyr/fff.h>
```

Zephyr provides several FFF-based fake drivers which can be used as either stubs or mocks. Fake driver instances are configured via *Devicetree* and *Configuration System (Kconfig)*. See the following devicetree bindings for more information:

- `zephyr,fake-can`
- `zephyr,fake-eeprom`

Zephyr also has defined extensions to FFF for simplified declarations of fake functions. See *FFF Extensions*.

Customizing Test Output

Customization is enabled by setting `CONFIG_ZTEST_TC_UTIL_USER_OVERRIDE` to "y" and adding a file `tc_util_user_override.h` with your overrides.

Add the line `zephyr_include_directories(my_folder)` to your project's `CMakeLists.txt` to let Zephyr find your header file during builds.

See the file subsys/testsuite/include/zephyr/tc_util.h to see which macros and/or defines can be overridden. These will be surrounded by blocks such as:

```
#ifndef SOMETHING
#define SOMETHING <default implementation>
#endif /* SOMETHING */
```

Shuffling Test Sequence

By default the tests are sorted and ran in alphanumerical order. Test cases may be dependent on this sequence. Enable `CONFIG_ZTEST_SHUFFLE` to randomize the order. The output from the test will display the seed for failed tests. For native simulator builds you can provide the seed as an argument to twister with *–seed*

Static configuration of ZTEST_SHUFFLE contains:

- `CONFIG_ZTEST_SHUFFLE_SUITE_REPEAT_COUNT` - Number of iterations the test suite will run.
- `CONFIG_ZTEST_SHUFFLE_TEST_REPEAT_COUNT` - Number of iterations the test will run.

Test Selection

For tests built for native simulator, use command line arguments to list or select tests to run. The test argument expects a comma separated list of `suite::test` . You can substitute the test name with an `*` to run all tests within a suite.

For example

```
$ zephyr.exe -list
$ zephyr.exe -test="fixture_tests::test_fixture_pointer,framework_tests::test_assert_mem_
↪equal"
$ zephyr.exe -test="framework_tests::*"
```

FFF Extensions

group `fff_extensions`

This module provides extensions to FFF for simplifying the configuration and usage of fakes.

Defines

`RETURN_HANDLED_CONTEXT`(FUNCNAME, CONTEXTTYPE, RESULTFIELD,
CONTEXTPTRNAME, HANDLERBODY)

Wrap custom fake body to extract defined context struct.

Add extension macro for simplified creation of fake functions needing call-specific context data.

This macro enables a fake to be implemented as follows and requires no familiarity with the inner workings of FFF.

```
struct FUNCNAME##_custom_fake_context
{
    struct instance * const instance;
    int result;
};

int FUNCNAME##_custom_fake(
    const struct instance **instance_out)
{
    RETURN_HANDLED_CONTEXT(
        FUNCNAME,
        struct FUNCNAME##_custom_fake_context,
        result,
        context,
        {
            if (context != NULL)
            {
                if (context->result == 0)
                {
                    if (instance_out != NULL)
                    {
                        *instance_out = context->instance;
                    }
                }
                return context->result;
            }
            return FUNCNAME##_fake.return_val;
        }
    );
}
```

Parameters

- `FUNCNAME` – Name of function being faked

- `CONTEXTTYPE` – type of custom defined fake context struct
- `RESULTFIELD` – name of field holding the return type & value
- `CONTEXTPTRNAME` – expected name of pointer to custom defined fake context struct
- `HANDLERBODY` – in-line custom fake handling logic

2.12.2 Test Runner (Twister)

Twister scans for the set of test applications in the git repository and attempts to execute them. By default, it tries to build each test application on boards marked as default in the board definition file.

The default options will build the majority of the test applications on a defined set of boards and will run in an emulated environment if available for the architecture or configuration being tested.

Because of the limited test execution coverage, twister cannot guarantee local changes will succeed in the full build environment, but it does sufficient testing by building samples and tests for different boards and different configurations to help keep the complete code tree buildable.

When using (at least) one `-v` option, twister's console output shows for every test application how the test is run (qemu, native_sim, etc.) or whether the binary was just built. There are a few reasons why twister only builds a test and doesn't run it:

- The test is marked as `build_only: true` in its `.yaml` configuration file.
- The test configuration has defined a `harness` but you don't have it or haven't set it up.
- The target device is not connected and not available for flashing
- You or some higher level automation invoked twister with `--build-only`.

To run the script in the local tree, follow the steps below:

Linux

```
$ source zephyr-env.sh
$ ./scripts/twister
```

Windows

```
zephyr-env.cmd
python .\scripts\twister
```

If you have a system with a large number of cores and plenty of free storage space, you can build and run all possible tests using the following options:

Linux

```
$ ./scripts/twister --all --enable-slow
```

Windows

```
python .\scripts\twister --all --enable-slow
```

This will build for all available boards and run all applicable tests in a simulated (for example QEMU) environment.

If you want to run tests on one or more specific platforms, you can use the `--platform` option, it is a platform filter for testing, with this option, test suites will only be built/run on the platforms specified. This option also supports different revisions of one same board, you can use `--platform board@revision` to test on a specific revision.

The list of command line options supported by twister can be viewed using:

Linux

```
$ ./scripts/twister --help
```

Windows

```
python .\scripts\twister --help
```

Board Configuration

To build tests for a specific board and to execute some of the tests on real hardware or in an emulation environment such as QEMU a board configuration file is required which is generic enough to be used for other tasks that require a board inventory with details about the board and its configuration that is only available during build time otherwise.

The board metadata file is located in the board directory and is structured using the YAML markup language. The example below shows a board with a data required for best test coverage for this specific board:

```
identifier: frdm_k64f
name: NXP FRDM-K64F
type: mcu
arch: arm
toolchain:
  - zephyr
  - gnuarmemb
  - xtools
supported:
  - arduino_gpio
  - arduino_i2c
  - netif:eth
  - adc
  - i2c
  - nvs
  - spi
  - gpio
  - usb_device
  - watchdog
  - can
  - pwm
testing:
  default: true
```

identifier:
A string that matches how the board is defined in the build system. This same string is used when building, for example when calling `west build` or `cmake`:

```
# with west
west build -b reel_board
# with cmake
cmake -DBOARD=reel_board ..
```

name:
The actual name of the board as it appears in marketing material.

type:
Type of the board or configuration, currently we support 2 types: mcu, qemu

simulation:
Simulator used to simulate the platform, e.g. qemu.

arch:
Architecture of the board

toolchain:
The list of supported toolchains that can build this board. This should match one of the values used for *ZEPHYR_TOOLCHAIN_VARIANT* when building on the command line

ram:
Available RAM on the board (specified in KB). This is used to match test scenario requirements. If not specified we default to 128KB.

flash:
Available FLASH on the board (specified in KB). This is used to match test scenario requirements. If not specified we default to 512KB.

supported:
A list of features this board supports. This can be specified as a single word feature or as a variant of a feature class. For example:

```
supported:
  - pci
```

This indicates the board does support PCI. You can make a test scenario build or run only on such boards, or:

```
supported:
  - netif:eth
  - sensor:bmi16
```

A test scenario can depend on 'eth' to only test ethernet or on 'netif' to run on any board with a networking interface.

testing:
testing relating keywords to provide best coverage for the features of this board.

default: [True|False]:
This is a default board, it will tested with the highest priority and is covered when invoking the simplified twister without any additional arguments.

ignore_tags:
Do not attempt to build (and therefore run) tests marked with this list of tags.

only_tags:
Only execute tests with this list of tags on a specific platform.

timeout_multiplier: <float> (default 1)
Multiply each test scenario timeout by specified ratio. This option allows to tune timeouts only for required platform. It can be useful in case naturally slow platform I.e.: HW board with power-efficient but slow CPU or simulation platform which can perform instruction accurate simulation but does it slowly.

env:
A list of environment variables. Twister will check if all these environment variables are set, and otherwise skip this platform. This allows the user to define a platform which should be used, for example, only if some required software or hardware is present, and to signal that presence to twister using these environment variables.

Tests

Tests are detected by the presence of a `testcase.yaml` or a `sample.yaml` files in the application's project directory. This test application configuration file may contain one or more entries in the tests section each identifying a test scenario.

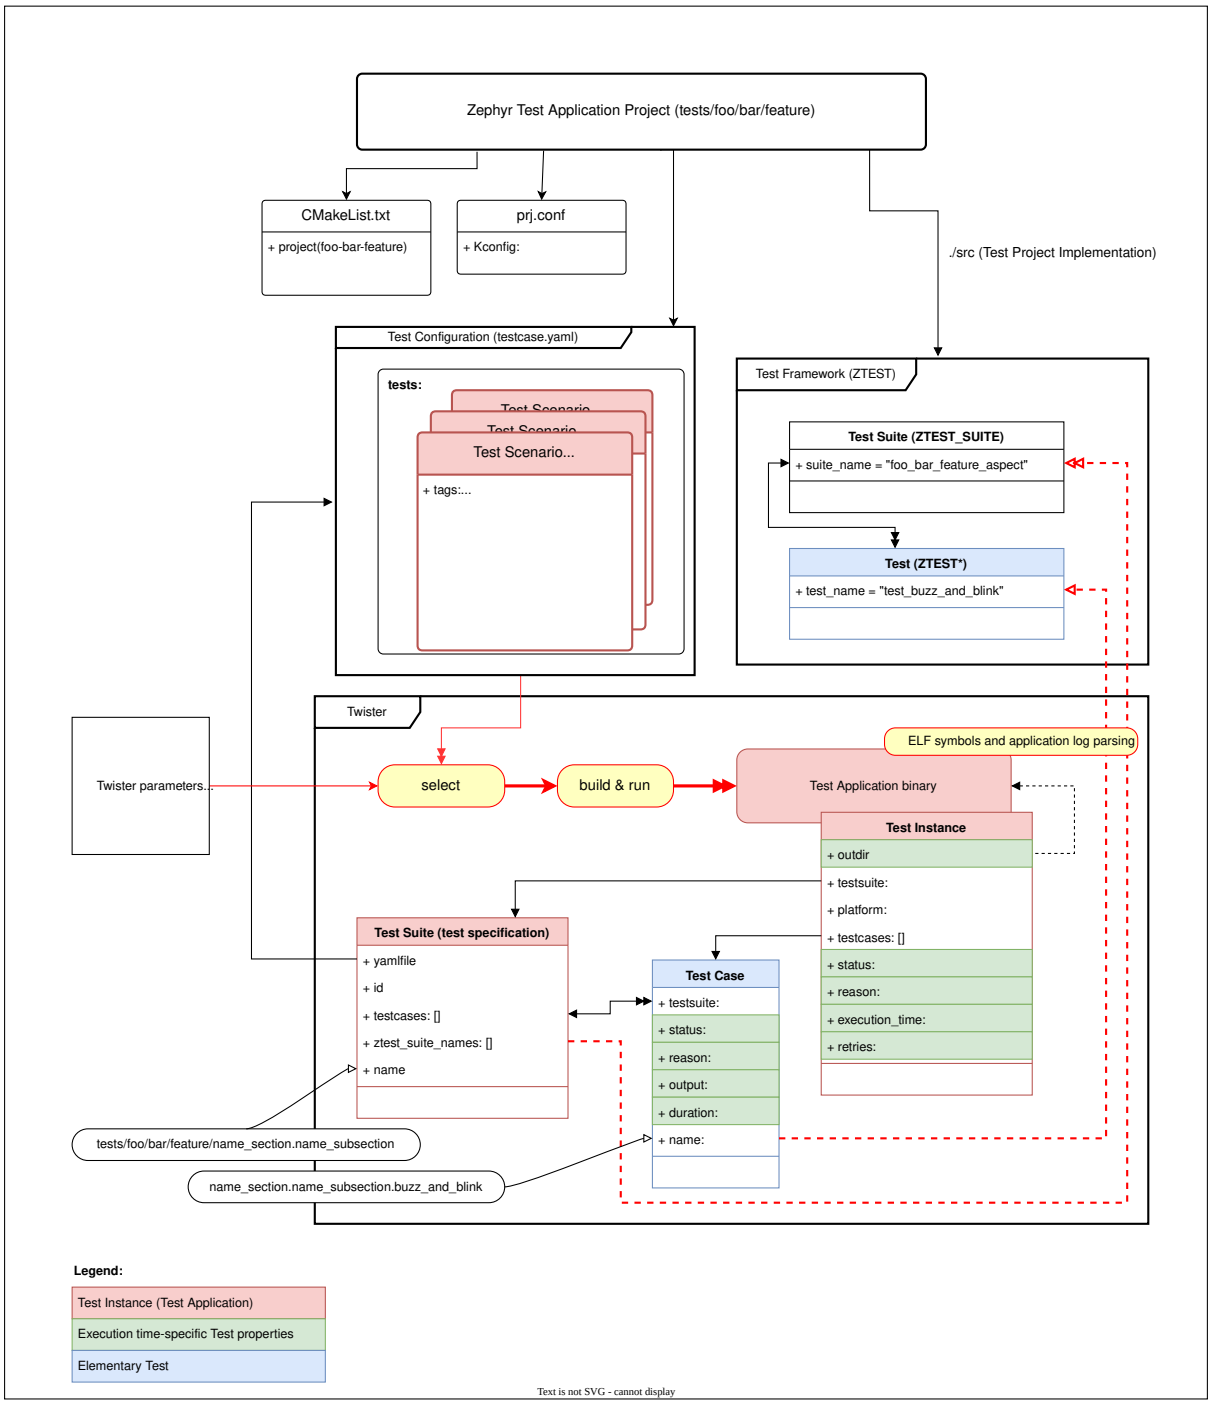

Fig. 4: Twister and a Test applications' project.

Test application configurations are written using the YAML syntax and share the same structure as samples.

A test scenario is a set of conditions or variables, defined in test scenario entry, under which a set of test suites will be executed. Can be used interchangeably with test scenario entry.

A test suite is a collection of test cases that are intended to be used to test a software program to ensure it meets certain requirements. The test cases in a test suite are often related or meant to be executed together.

The name of each test scenario needs to be unique in the context of the overall test application and has to follow basic rules:

1. The format of the test scenario identifier shall be a string without any spaces or special characters (allowed characters: alphanumeric and [_=]) consisting of multiple sections delimited with a dot (.).
2. Each test scenario identifier shall start with a section followed by a subsection separated by a dot. For example, a test scenario that covers semaphores in the kernel shall start with `kernel.semaphore`.
3. All test scenario identifiers within a `testcase.yaml` file need to be unique. For example a `testcase.yaml` file covering semaphores in the kernel can have:
   - `kernel.semaphore`: For general semaphore tests
   - `kernel.semaphore.stress`: Stress testing semaphores in the kernel.
4. Depending on the nature of the test, an identifier can consist of at least two sections:
   - Ztest tests: The individual test cases in the ztest testsuite will be concatenated by dot (.) to the identifier in the `testcase.yaml` file generating unique identifiers for every test case in the suite.
   - Standalone tests and samples: This type of test should at least have 3 sections concatnated by dot (.) in the test scenario identifier in the `testcase.yaml` (or `sample.yaml`) file. The last section of the name shall signify the test case itself.

The following is an example test configuration with a few options that are explained in this document.

```
tests:
  bluetooth.gatt:
    build_only: true
    platform_allow: qemu_cortex_m3 qemu_x86
    tags: bluetooth
  bluetooth.gatt.br:
    build_only: true
    extra_args: CONF_FILE="prj_br.conf"
    filter: not CONFIG_DEBUG
    platform_exclude: up_squared
    platform_allow: qemu_cortex_m3 qemu_x86
    tags: bluetooth
```

A sample with tests will have the same structure with additional information related to the sample and what is being demonstrated:

```
sample:
  name: hello world
  description: Hello World sample, the simplest Zephyr application
tests:
  sample.basic.hello_world:
    build_only: true
    tags: tests
    min_ram: 16
```

(continues on next page)

(continued from previous page)

```
  sample.basic.hello_world.singlethread:
    build_only: true
    extra_args: CONF_FILE=prj_single.conf
    filter: not CONFIG_BT
    tags: tests
    min_ram: 16
```

The full canonical name for each test scenario is:`<path to test application>/<test scenario identifier>`

A test scenario entry is a a block or entry starting with test scenario identifier in the YAML files.

Each test scenario entry in the test application configuration can define the following key/value pairs:

tags: <list of tags> (required)
A set of string tags for the test scenario. Usually pertains to functional domains but can be anything. Command line invocations of this script can filter the set of tests to run based on tag.

skip: <True|False> (default False)
skip test scenario unconditionally. This can be used for broken tests for example.

slow: <True|False> (default False)
Don't run this test scenario unless `--enable-slow` or `--enable-slow-only` was passed in on the command line. Intended for time-consuming test scenarios that are only run under certain circumstances, like daily builds. These test scenarios are still compiled.

extra_args: <list of extra arguments>
Extra arguments to pass to build tool when building or running the test scenario.

extra_configs: <list of extra configurations>
Extra configuration options to be merged with a main prj.conf when building or running the test scenario. For example:

```
common:
  tags: drivers adc
tests:
  test:
    depends_on: adc
  test_async:
    extra_configs:
      - CONFIG_ADC_ASYNC=y
```

Using namespacing, it is possible to apply a configuration only to some hardware. Currently both architectures and platforms are supported:

```
common:
  tags: drivers adc
tests:
  test:
    depends_on: adc
  test_async:
    extra_configs:
      - arch:x86:CONFIG_ADC_ASYNC=y
      - platform:qemu_x86:CONFIG_DEBUG=y
```

build_only: <True|False> (default False)
If true, twister will not try to run the test even if the test is runnable on the platform.

This keyword is reserved for tests that are used to test if some code actually builds. A `build_only` test is not designed to be run in any environment and should not be testing any functionality, it only verifies that the code builds.

This option is often used to test drivers and the fact that they are correctly enabled in Zephyr and that the code builds, for example sensor drivers. Such test shall not be used to verify the functionality of the driver.

build_on_all: <True|False> (default False)
If true, attempt to build test scenario on all available platforms. This is mostly used in CI for increased coverage. Do not use this flag in new tests.

depends_on: <list of features>
A board or platform can announce what features it supports, this option will enable the test only those platforms that provide this feature.

levels: <list of levels>
Test levels this test should be part of. If a level is present, this test will be selectable using the command line option `--level <level name>`

min_ram: <integer>
minimum amount of RAM in KB needed for this test to build and run. This is compared with information provided by the board metadata.

min_flash: <integer>
minimum amount of ROM in KB needed for this test to build and run. This is compared with information provided by the board metadata.

timeout: <number of seconds>
Length of time to run test before automatically killing it. Default to 60 seconds.

arch_allow: <list of arches, such as x86, arm, arc>
Set of architectures that this test scenario should only be run for.

arch_exclude: <list of arches, such as x86, arm, arc>
Set of architectures that this test scenario should not run on.

platform_allow: <list of platforms>
Set of platforms that this test scenario should only be run for. Do not use this option to limit testing or building in CI due to time or resource constraints, this option should only be used if the test or sample can only be run on the allowed platform and nothing else.

integration_platforms: <YML list of platforms/boards>
This option limits the scope to the listed platforms when twister is invoked with the `--integration` option. Use this instead of platform_allow if the goal is to limit scope due to timing or resource constraints.

platform_exclude: <list of platforms>
Set of platforms that this test scenario should not run on.

extra_sections: <list of extra binary sections>
When computing sizes, twister will report errors if it finds extra, unexpected sections in the Zephyr binary unless they are named here. They will not be included in the size calculation.

sysbuild: <True|False> (default False)
Build the project using sysbuild infrastructure. Only the main project's generated device-tree and Kconfig will be used for filtering tests. on device testing must use the hardware map, or west flash to load the images onto the target. The `--erase` option of west flash is not supported with this option. Usage of unsupported options will result in tests requiring sysbuild support being skipped.

harness: <string>
A harness keyword in the `testcase.yaml` file identifies a Twister harness needed to run a test successfully. A harness is a feature of Twister and implemented by Twister, some harnesses are defined as placeholders and have no implementation yet.

A harness can be seen as the handler that needs to be implemented in Twister to be able to evaluate if a test passes criteria. For example, a keyboard harness is set on tests that require keyboard interaction to reach verdict on whether a test has passed or failed, however, Twister lack this harness implementation at the moment.

Supported harnesses:

- ztest
- test
- console
- pytest
- gtest
- robot

Harnesses `ztest`, `gtest` and `console` are based on parsing of the output and matching certain phrases. `ztest` and `gtest` harnesses look for pass/fail/etc. frames defined in those frameworks. Use `gtest` harness if you've already got tests written in the gTest framework and do not wish to update them to zTest. The `console` harness tells Twister to parse a test's text output for a regex defined in the test's YAML file. The `robot` harness is used to execute Robot Framework test suites in the Renode simulation framework.

Some widely used harnesses that are not supported yet:

- keyboard
- net
- bluetooth

Harness `bsim` is implemented in limited way - it helps only to copy the final executable (`zephyr.exe`) from build directory to BabbleSim's `bin` directory (`${BSIM_OUT_PATH}/bin`). This action is useful to allow BabbleSim's tests to directly run after. By default, the executable file name is (with dots and slashes replaced by underscores): `bs_<platform_name>_<test_path>_<test_scenario_name>`. This name can be overridden with the `bsim_exe_name` option in `harness_config` section.

platform_key: <list of platform attributes>
Often a test needs to only be built and run once to qualify as passing. Imagine a library of code that depends on the platform architecture where passing the test on a single platform for each arch is enough to qualify the tests and code as passing. The platform_key attribute enables doing just that.

For example to key on (arch, simulation) to ensure a test is run once per arch and simulation (as would be most common):

```
platform_key:
  - arch
  - simulation
```

Adding platform (board) attributes to include things such as soc name, soc family, and perhaps sets of IP blocks implementing each peripheral interface would enable other interesting uses. For example, this could enable building and running SPI tests once for each unique IP block.

harness_config: <harness configuration options>
Extra harness configuration options to be used to select a board and/or for handling generic Console with regex matching. Config can announce what features it supports. This option will enable the test to run on only those platforms that fulfill this external dependency.

The following options are currently supported:

type: <one_line|multi_line> (required)
Depends on the regex string to be matched

regex: <list of regular expressions> (required)
Strings with regular expressions to match with the test's output to confirm the test runs as expected.

ordered: <True|False> (default False)
Check the regular expression strings in orderly or randomly fashion

record: <recording options> (optional)

regex: <regular expression> (required)
The regular expression with named subgroups to match data fields at the test's output lines where the test provides some custom data for further analysis. These records will be written into the build directory `recording.csv` file as well as `recording` property of the test suite object in `twister.json`.

For example, to extract three data fields `metric`, `cycles`, `nanoseconds`:

```
record:
  regex: "(?P<metric>.*):(?P<cycles>.*) cycles, (?P<nanoseconds>.*) ns"
```

as_json: <list of regex subgroup names> (optional)
Data fields, extracted by the regular expression into named subgroups, which will be additionally parsed as JSON encoded strings and written into `twister.json` as nested `recording` object properties. The corresponding `recording.csv` columns will contain strings as-is.

Using this option, a test log can convey layered data structures passed from the test image for further analysis with summary results, traces, statistics, etc.

For example, this configuration:

```
record:
  regex: "RECORD:(?P<type>.*):DATA:(?P<metrics>.*)"
  as_json: [metrics]
```

when matched to a test log string:

```
RECORD:jitter_drift:DATA:{"rollovers":0, "mean_us":1000.0}
```

will be reported in `twister.json` as:

```
"recording":[
    {
        "type":"jitter_drift",
        "metrics":{
            "rollovers":0,
            "mean_us":1000.0
        }
    }
]
```

fixture: <expression>
Specify a test scenario dependency on an external device(e.g., sensor), and identify setups that fulfill this dependency. It depends on specific test setup and board selection logic to pick the particular board(s) out of multiple boards that fulfill the dependency in an automation setup based on `fixture` keyword. Some sample fixture names are i2c_hts221, i2c_bme280, i2c_FRAM, ble_fw and gpio_loop.

Only one fixture can be defined per test scenario and the fixture name has to be unique across all tests in the test suite.

pytest_root: <list of pytest testpaths> (default pytest)
Specify a list of pytest directories, files or subtests that need to be executed when a test scenario begins to run. The default pytest directory is `pytest`. After the pytest run is finished, Twister will check if the test scenario passed or failed according to the pytest report. As an example, a list of valid pytest roots is presented below:

```
harness_config:
  pytest_root:
    - "pytest/test_shell_help.py"
    - "../shell/pytest/test_shell.py"
    - "/tmp/test_shell.py"
    - "~/tmp/test_shell.py"
    - "$ZEPHYR_BASE/samples/subsys/testsuite/pytest/shell/pytest/test_shell.
↪py"
    - "pytest/test_shell_help.py::test_shell2_sample"  # select pytest␣
↪subtest
    - "pytest/test_shell_help.py::test_shell2_sample[param_a]"  # select␣
↪pytest parametrized subtest
```

pytest_args: <list of arguments> (default empty)
Specify a list of additional arguments to pass to pytest e.g.: pytest_args: ['-k=test_method', '--log-level=DEBUG']. Note that --pytest-args can be passed multiple times to pass several arguments to the pytest.

pytest_dut_scope: <function|class|module|package|session> (default function)
The scope for which dut and shell pytest fixtures are shared. If the scope is set to function, DUT is launched for every test case in python script. For session scope, DUT is launched only once.

robot_testsuite: <robot file path> (default empty)
Specify one or more paths to a file containing a Robot Framework test suite to be run.

robot_option: <robot option> (default empty)
One or more options to be send to robotframework.

bsim_exe_name: <string>
If provided, the executable filename when copying to BabbleSim's bin directory, will be bs_<platform_name>_<bsim_exe_name> instead of the default based on the test path and scenario name.

The following is an example yaml file with a few harness_config options.

```
sample:
  name: HTS221 Temperature and Humidity Monitor
common:
  tags: sensor
  harness: console
  harness_config:
    type: multi_line
    ordered: false
    regex:
      - "Temperature:(.*)C"
      - "Relative Humidity:(.*)%"
    fixture: i2c_hts221
tests:
  test:
    tags: sensors
    depends_on: i2c
```

The following is an example yaml file with pytest harness_config options, default pytest_root name "pytest" will be used if pytest_root not specified. please refer the examples in samples/subsys/testsuite/pytest/.

```
common:
  harness: pytest
tests:
  pytest.example.directories:
```

(continues on next page)

(continued from previous page)

```
    harness_config:
      pytest_root:
        - pytest_dir1
        - $ENV_VAR/samples/test/pytest_dir2
  pytest.example.files_and_subtests:
    harness_config:
      pytest_root:
        - pytest/test_file_1.py
        - test_file_2.py::test_A
        - test_file_2.py::test_B[param_a]
```

The following is an example yaml file with robot harness_config options.

```
tests:
  robot.example:
    harness: robot
    harness_config:
      robot_testsuite: [robot file path]
```

It can be more than one test suite using a list.

```
tests:
  robot.example:
    harness: robot
    harness_config:
      robot_testsuite:
        - [robot file path 1]
        - [robot file path 2]
        - [robot file path n]
```

One or more options can be passed to robotframework.

```
tests:
  robot.example:
    harness: robot
    harness_config:
      robot_testsuite: [robot file path]
      robot_option:
        - --exclude tag
        - --stop-on-error
```

filter: <expression>
Filter whether the test scenario should be run by evaluating an expression against an environment containing the following values:

```
{ ARCH : <architecture>,
  PLATFORM : <platform>,
  <all CONFIG_* key/value pairs in the test's generated defconfig>,
  *<env>: any environment variable available
}
```

Twister will first evaluate the expression to find if a “limited” cmake call, i.e. using package_helper cmake script, can be done. Existence of “dt_*” entries indicates devicetree is needed. Existence of “CONFIG*” entries indicates kconfig is needed. If there are no other types of entries in the expression a filtration can be done without creating a complete build system. If there are entries of other types a full cmake is required.

The grammar for the expression language is as follows:

```
expression : expression 'and' expression
           | expression 'or' expression
```

(continues on next page)

(continued from previous page)

```
            | 'not' expression
            | '(' expression ')'
            | symbol '==' constant
            | symbol '!=' constant
            | symbol '<' NUMBER
            | symbol '>' NUMBER
            | symbol '>=' NUMBER
            | symbol '<=' NUMBER
            | symbol 'in' list
            | symbol ':' STRING
            | symbol
            ;

list : '[' list_contents ']';

list_contents : constant (',' constant)*;

constant : NUMBER | STRING;
```

For the case where `expression ::= symbol`, it evaluates to `true` if the symbol is defined to a non-empty string.

Operator precedence, starting from lowest to highest:

- or (left associative)
- and (left associative)
- not (right associative)
- all comparison operators (non-associative)

`arch_allow`, `arch_exclude`, `platform_allow`, `platform_exclude` are all syntactic sugar for these expressions. For instance:

```
arch_exclude = x86 arc
```

Is the same as:

```
filter = not ARCH in ["x86", "arc"]
```

The `:` operator compiles the string argument as a regular expression, and then returns a true value only if the symbol's value in the environment matches. For example, if `CONFIG_SOC="stm32f107xc"` then

```
filter = CONFIG_SOC : "stm.*"
```

Would match it.

required_snippets: <list of needed snippets>

Snippets are supported in twister for test scenarios that require them. As with normal applications, twister supports using the base zephyr snippet directory and test application directory for finding snippets. Listed snippets will filter supported tests for boards (snippets must be compatible with a board for the test to run on them, they are not optional).

The following is an example yaml file with 2 required snippets.

```
tests:
  snippet.example:
    required_snippets:
      - cdc-acm-console
      - user-snippet-example
```

The set of test scenarios that actually run depends on directives in the test scenario filed and options passed in on the command line. If there is any confusion, running with `-v` or examining the discard report (`twister_discard.csv`) can help show why particular test scenarios were skipped.

Metrics (such as pass/fail state and binary size) for the last code release are stored in `scripts/release/twister_last_release.csv`. To update this, pass the `--all --release` options.

To load arguments from a file, add + before the file name, e.g., `+file_name`. File content must be one or more valid arguments separated by line break instead of white spaces.

Most everyday users will run with no arguments.

Managing tests timeouts

There are several parameters which control tests timeouts on various levels:

- `timeout` option in each test scenario. See *here* for more details.
- `timeout_multiplier` option in board configuration. See *here* for more details.
- `--timeout-multiplier` twister option which can be used to adjust timeouts in exact twister run. It can be useful in case of simulation platform as simulation time may depend on the host speed & load or we may select different simulation method (i.e. cycle accurate but slower one), etc...

Overall test scenario timeout is a multiplication of these three parameters.

Running in Integration Mode

This mode is used in continuous integration (CI) and other automated environments used to give developers fast feedback on changes. The mode can be activated using the `--integration` option of twister and narrows down the scope of builds and tests if applicable to platforms defined under the integration keyword in the test configuration file (`testcase.yaml` and `sample.yaml`).

Running tests on custom emulator

Apart from the already supported QEMU and other simulated environments, Twister supports running any out-of-tree custom emulator defined in the board's `board.cmake`. To use this type of simulation, add the following properties to `custom_board/custom_board.yaml`:

```
simulation: custom
simulation_exec: <name_of_emu_binary>
```

This tells Twister that the board is using a custom emulator called `<name_of_emu_binary>`, make sure this binary exists in the PATH.

Then, in `custom_board/board.cmake`, set the supported emulation platforms to `custom`:

```
set(SUPPORTED_EMU_PLATFORMS custom)
```

Finally, implement the `run_custom` target in `custom_board/board.cmake`. It should look something like this:

```
add_custom_target(run_custom
  COMMAND
  <name_of_emu_binary to invoke during 'run'>
  <any args to be passed to the command, i.e. ${BOARD}, ${APPLICATION_BINARY_DIR}/zephyr/
↪zephyr.elf>
```

(continues on next page)

(continued from previous page)

```
  WORKING_DIRECTORY ${APPLICATION_BINARY_DIR}
  DEPENDS ${logical_target_for_zephyr_elf}
  USES_TERMINAL
  )
```

Running Tests on Hardware

Beside being able to run tests in QEMU and other simulated environments, twister supports running most of the tests on real devices and produces reports for each run with detailed FAIL/PASS results.

Executing tests on a single device To use this feature on a single connected device, run twister with the following new options:

Linux

```
scripts/twister --device-testing --device-serial /dev/ttyACM0 \
--device-serial-baud 115200 -p frdm_k64f  -T tests/kernel
```

Windows

```
python .\scripts\twister --device-testing --device-serial COM1 \
--device-serial-baud 115200 -p frdm_k64f  -T tests/kernel
```

The `--device-serial` option denotes the serial device the board is connected to. This needs to be accessible by the user running twister. You can run this on only one board at a time, specified using the `--platform` option.

The `--device-serial-baud` option is only needed if your device does not run at 115200 baud.

To support devices without a physical serial port, use the `--device-serial-pty` option. In this cases, log messages are captured for example using a script. In this case you can run twister with the following options:

Linux

```
scripts/twister --device-testing --device-serial-pty "script.py" \
-p intel_adsp/cavs25 -T tests/kernel
```

Windows

> **Note**
>
> Not supported on Windows OS

The script is user-defined and handles delivering the messages which can be used by twister to determine the test execution status.

The `--device-flash-timeout` option allows to set explicit timeout on the device flash operation, for example when device flashing takes significantly large time.

The `--device-flash-with-test` option indicates that on the platform the flash operation also executes a test scenario, so the flash timeout is increased by a test scenario timeout.

Executing tests on multiple devices To build and execute tests on multiple devices connected to the host PC, a hardware map needs to be created with all connected devices and their details

such as the serial device, baud and their IDs if available. Run the following command to produce the hardware map:

Linux

```
./scripts/twister --generate-hardware-map map.yml
```

Windows

```
python .\scripts\twister --generate-hardware-map map.yml
```

The generated hardware map file (map.yml) will have the list of connected devices, for example:

Linux

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: unknown
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
- connected: true
  id: 000683759358
  platform: unknown
  product: J-Link
  runner: unknown
  serial: /dev/cu.usbmodem0006837593581
```

Windows

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: unknown
  product: unknown
  runner: unknown
  serial: COM1
- connected: true
  id: 000683759358
  platform: unknown
  product: unknown
  runner: unknown
  serial: COM2
```

Any options marked as unknown need to be changed and set with the correct values, in the above example the platform names, the products and the runners need to be replaced with the correct values corresponding to the connected hardware. In this example we are using a reel_board and an nrf52840dk/nrf52840:

Linux

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
  baud: 9600
- connected: true
  id: 000683759358
  platform: nrf52840dk/nrf52840
  product: J-Link
  runner: nrfjprog
  serial: /dev/cu.usbmodem0006837593581
  baud: 9600
```

Windows

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: COM1
  baud: 9600
- connected: true
  id: 000683759358
  platform: nrf52840dk/nrf52840
  product: J-Link
  runner: nrfjprog
  serial: COM2
  baud: 9600
```

The baud entry is only needed if not running at 115200.

If the map file already exists, then new entries are added and existing entries will be updated. This way you can use one single master hardware map and update it for every run to get the correct serial devices and status of the devices.

With the hardware map ready, you can run any tests by pointing to the map

Linux

```
./scripts/twister --device-testing --hardware-map map.yml -T samples/hello_world/
```

Windows

```
python .\scripts\twister --device-testing --hardware-map map.yml -T samples\hello_world
```

The above command will result in twister building tests for the platforms defined in the hardware map and subsequently flashing and running the tests on those platforms.

Note

Currently only boards with support for pyocd, nrfjprog, jlink, openocd, or dediprog are supported with the hardware map features. Boards that require other runners to flash the Zephyr binary are still work in progress.

Hardware map allows to set `--device-flash-timeout` and `--device-flash-with-test` command line options as `flash-timeout` and `flash-with-test` fields respectively. These hardware map values override command line options for the particular platform.

Serial PTY support using `--device-serial-pty` can also be used in the hardware map:

```
- connected: true
  id: None
  platform: intel_adsp/cavs25
  product: None
  runner: intel_adsp
  serial_pty: path/to/script.py
  runner_params:
    - --remote-host=remote_host_ip_addr
    - --key=/path/to/key.pem
```

The runner_params field indicates the parameters you want to pass to the west runner. For some boards the west runner needs some extra parameters to work. It is equivalent to following west and twister commands.

Linux

```
west flash --remote-host remote_host_ip_addr --key /path/to/key.pem

twister -p intel_adsp/cavs25 --device-testing --device-serial-pty script.py
--west-flash="--remote-host=remote_host_ip_addr,--key=/path/to/key.pem"
```

Windows

Note

Not supported on Windows OS

Note

For serial PTY, the "–generate-hardware-map" option cannot scan it out and generate a correct hardware map automatically. You have to edit it manually according to above example. This is because the serial port of the PTY is not fixed and being allocated in the system at runtime.

Fixtures Some tests require additional setup or special wiring specific to the test. Running the tests without this setup or test fixture may fail. A test scenario can specify the fixture it needs which can then be matched with hardware capability of a board and the fixtures it supports via the command line or using the hardware map file.

Fixtures are defined in the hardware map file as a list:

```
- connected: true
  fixtures:
    - gpio_loopback
  id: 0240000026334e450015400f5e0e000b4eb1000097969900
  platform: frdm_k64f
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/ttyACM9
```

When running `twister` with `--device-testing`, the configured fixture in the hardware map file will be matched to test scenarios requesting the same fixtures and these tests will be executed on the boards that provide this fixture.

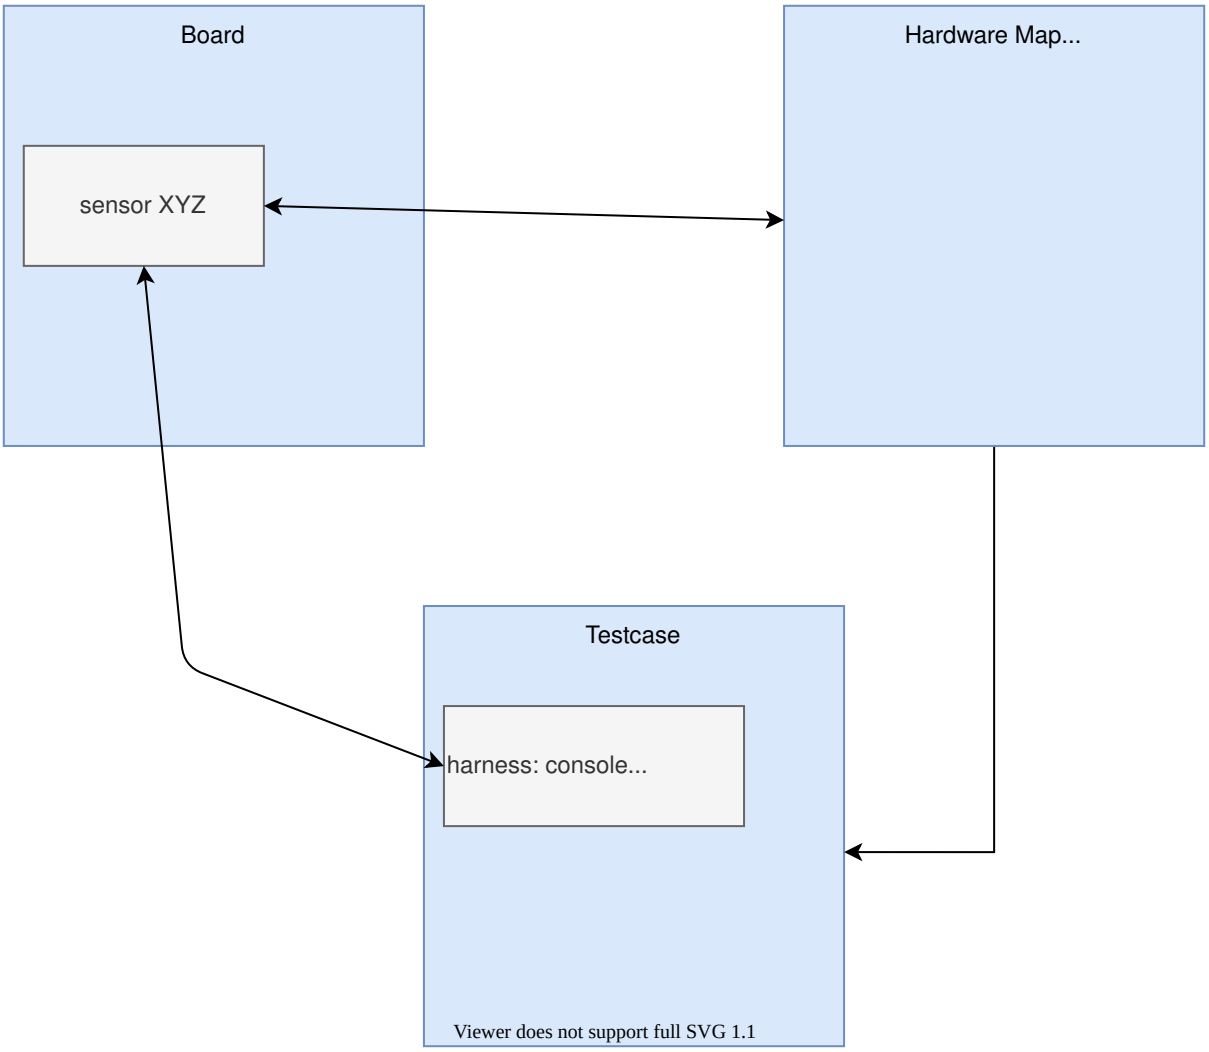
Fixtures can also be provided via twister command option `--fixture`, this option can be used multiple times and all given fixtures will be appended as a list. And the given fixtures will be assigned to all boards, this means that all boards set by current twister command can run those test scenarios which request the same fixtures.

Some fixtures allow for configuration strings to be appended, separated from the fixture name by a `:`. Only the fixture name is matched against the fixtures requested by test scenarios.

Notes It may be useful to annotate board descriptions in the hardware map file with additional information. Use the `notes` keyword to do this. For example:

```
- connected: false
  fixtures:
    - gpio_loopback
  id: 000683290670
  notes: An nrf5340dk/nrf5340 is detected as an nrf52840dk/nrf52840 with no serial
    port, and three serial ports with an unknown platform.  The board id of the serial
    ports is not the same as the board id of the development kit.  If you regenerate
    this file you will need to update serial to reference the third port, and platform
```

(continues on next page)



Board
sensor XYZ
Hardware Map...
Testcase
harness: console...
Viewer does not support full SVG 1.1

(continued from previous page)

```
    to nrf5340dk/nrf5340/cpuapp or another supported board target.
  platform: nrf52840dk/nrf52840
  product: J-Link
  runner: jlink
  serial: null
```

Overriding Board Identifier When (re-)generated the hardware map file will contain an `id` keyword that serves as the argument to `--board-id` when flashing. In some cases the detected ID is not the correct one to use, for example when using an external J-Link probe. The `probe_id` keyword overrides the `id` keyword for this purpose. For example:

```
- connected: false
  id: 0229000005d9ebc600000000000000000000000097969905
  platform: mimxrt1060_evk
  probe_id: 000609301751
  product: DAPLink CMSIS-DAP
  runner: jlink
  serial: null
```

Quarantine Twister allows user to provide configuration files defining a list of tests or platforms to be put under quarantine. Such tests will be skipped and marked accordingly in the output reports. This feature is especially useful when running larger test suits, where a failure of one test can affect the execution of other tests (e.g. putting the physical board in a corrupted state).

To use the quarantine feature one has to add the argument `--quarantine-list <PATH_TO_QUARANTINE_YAML>` to a twister call. Multiple quarantine files can be used. The current status of tests on the quarantine list can also be verified by adding `--quarantine-verify` to the above argument. This will make twister skip all tests which are not on the given list.

A quarantine yaml has to be a sequence of dictionaries. Each dictionary has to have `scenarios` and `platforms` entries listing combinations of scenarios and platforms to put under quarantine. In addition, an optional entry `comment` can be used, where some more details can be given (e.g. link to a reported issue). These comments will also be added to the output reports.

When quarantining a class of tests or many scenarios in a single testsuite or when dealing with multiple issues within a subsystem, it is possible to use regular expressions, for example, **kernel.*** would quarantine all kernel tests.

An example of entries in a quarantine yaml:

```
- scenarios:
    - sample.basic.helloworld
  comment: "Link to the issue: https://github.com/zephyrproject-rtos/zephyr/pull/33287"

- scenarios:
    - kernel.common
    - kernel.common.(misra|tls)
    - kernel.common.nano64
  platforms:
    - .*_cortex_.*
    - native_sim
```

To exclude a platform, use the following syntax:

```
- platforms:
  - qemu_x86
  comment: "broken qemu"
```

Additionally you can quarantine entire architectures or a specific simulator for executing tests.

Test Configuration

A test configuration can be used to customize various aspects of twister and the default enabled options and features. This allows tweaking the filtering capabilities depending on the environment and makes it possible to adapt and improve coverage when targeting different sets of platforms.

The test configuration also adds support for test levels and the ability to assign a specific test to one or more levels. Using command line options of twister it is then possible to select a level and just execute the tests included in this level.

Additionally, the test configuration allows defining level dependencies and additional inclusion of tests into a specific level if the test itself does not have this information already.

In the configuration file you can include complete components using regular expressions and you can specify which test level to import from the same file, making management of levels easier.

To help with testing outside of upstream CI infrastructure, additional options are available in the configuration file, which can be hosted locally. As of now, those options are available:

- Ability to ignore default platforms as defined in board definitions (Those are mostly emulation platforms used to run tests in upstream CI)
- Option to specify your own list of default platforms overriding what upstream defines.
- Ability to override *build_on_all* options used in some test scenarios. This will treat tests or sample as any other just build for default platforms you specify in the configuration file or on the command line.
- Ignore some logic in twister to expand platform coverage in cases where default platforms are not in scope.

Platform Configuration The following options control platform filtering in twister:

- *override_default_platforms*: override default key a platform sets in board configuration and instead use the list of platforms provided in the configuration file as the list of default platforms. This option is set to False by default.
- *increased_platform_scope*: This option is set to True by default, when disabled, twister will not increase platform coverage automatically and will only build and run tests on the specified platforms.
- *default_platforms*: A list of additional default platforms to add. This list can either be used to replace the existing default platforms or can extend it depending on the value of *override_default_platforms*.

And example platforms configuration:

```
platforms:
  override_default_platforms: true
  increased_platform_scope: false
  default_platforms:
    - qemu_x86
```

Test Level Configuration The test configuration allows defining test levels, level dependencies and additional inclusion of tests into a specific test level if the test itself does not have this information already.

In the configuration file you can include complete components using regular expressions and you can specify which test level to import from the same file, making management of levels simple.

And example test level configuration:

```
levels:
  - name: my-test-level
    description: >
      my custom test level
    adds:
      - kernel.threads.*
      - kernel.timer.behavior
      - arch.interrupt
      - boards.*
```

Combined configuration To mix the Platform and level configuration, you can take an example as below:

An example platforms plus level configuration:

```
platforms:
  override_default_platforms: true
  default_platforms:
    - frdm_k64f
levels:
  - name: smoke
    description: >
        A plan to be used verifying basic zephyr features.
  - name: unit
    description: >
        A plan to be used verifying unit test.
  - name: integration
    description: >
        A plan to be used verifying integration.
  - name: acceptance
    description: >
        A plan to be used verifying acceptance.
  - name: system
    description: >
        A plan to be used verifying system.
  - name: regression
    description: >
        A plan to be used verifying regression.
```

To run with above test_config.yaml file, only default_platforms with given test level test scenarios will run.

Linux

```
scripts/twister --test-config=<path to>/test_config.yaml
 -T tests --level="smoke"
```

Running in Tests in Random Order

Enable ZTEST framework's `CONFIG_ZTEST_SHUFFLE` config option to run your tests in random order. This can be beneficial for identifying dependencies between test cases. For native_sim platforms, you can provide the seed to the random number generator by providing `-seed=value` as an argument to twister. See *Shuffling Test Sequence* for more details.

Robot Framework Tests

Zephyr supports Robot Framework as one of solutions for automated testing.

Robot files allow you to express interactive test scenarios in human-readable text format and execute them in simulation or against hardware. At this moment Zephyr integration supports running Robot tests in the Renode simulation framework.

To execute a Robot test suite with twister, run the following command:

Linux

```
$ ./scripts/twister --platform hifive1 --test samples/subsys/shell/shell_module/sample.
↪shell.shell_module.robot
```

Windows

```
python .\scripts\twister --platform hifive1 --test samples/subsys/shell/shell_module/sample.
↪shell.shell_module.robot
```

Writing Robot tests For the list of keywords provided by the Robot Framework itself, refer to the official Robot documentation.

Information on writing and running Robot Framework tests in Renode can be found in the testing section of Renode documentation. It provides a list of the most commonly used keywords together with links to the source code where those are defined.

It's possible to extend the framework by adding new keywords expressed directly in Robot test suite files, as an external Python library or, like Renode does it, dynamically via XML-RPC. For details see the extending Robot Framework section in the official Robot documentation.

Running a single testsuite To run a single testsuite instead of a whole group of test you can run:

```
$ twister -p qemu_riscv32 -s tests/kernel/interrupt/arch.shared_interrupt
```

2.12.3 Twister blackbox tests

This guide aims to explain the structure of a test file so the reader will be able to understand existing files and create their own. All developers should fix any tests they break and create new ones when introducing new features, so this knowledge is important for any Twister developer.

Basics

Twister blackbox tests are written in python, using the `pytest` library. Read up on it *here* . Auxiliary test data follows whichever format it was in originally. Tests and data are wholly contained in the scripts/tests/twister_blackbox directory and prepended with `test_`.

Blackbox tests should not be aware of the internal twister code. Instead, they should call twister as user would and check the results.

Sample test file

```python
#!/usr/bin/env python3
# Copyright (c) 2024 Intel Corporation
#
# SPDX-License-Identifier: Apache-2.0

import importlib
import mock
import os
import pytest
import sys
import json

from conftest import ZEPHYR_BASE, TEST_DATA, testsuite_filename_mock
from twisterlib.testplan import TestPlan

class TestDummy:
    TESTDATA_X = [
        ("smoke", 5),
        ("acceptance", 6),
    ]

    @classmethod
    def setup_class(cls):
        apath = os.path.join(ZEPHYR_BASE, "scripts", "twister")
        cls.loader = importlib.machinery.SourceFileLoader("__main__", apath)
        cls.spec = importlib.util.spec_from_loader(cls.loader.name, cls.loader)
        cls.twister_module = importlib.util.module_from_spec(cls.spec)

    @classmethod
    def teardown_class(cls):
        pass

    @pytest.mark.parametrize(
        "level, expected_tests", TESTDATA_X, ids=["smoke", "acceptance"]
    )
    @mock.patch.object(TestPlan, "TESTSUITE_FILENAME", testsuite_filename_mock)
    def test_level(self, capfd, out_path, level, expected_tests):
        # Select platforms used for the tests
        test_platforms = ["qemu_x86", "frdm_k64f"]
        # Select test root
        path = os.path.join(TEST_DATA, "tests")
        config_path = os.path.join(TEST_DATA, "test_config.yaml")

        # Set flags for our Twister command as a list of strs
        args = (
            # Flags related to the generic test setup:
            # * Control the level of detail in stdout/err
            # * Establish the output directory
            # * Select Zephyr tests to use
            # * Control whether to only build or build and run aforementioned tests
            ["-i", "--outdir", out_path, "-T", path, "-y"]
            # Flags under test
            + ["--level", level]
            # Flags required for the test
            + ["--test-config", config_path]
            # Flags related to platform selection
            + [
                val
                for pair in zip(["-p"] * len(test_platforms), test_platforms)
                for val in pair
            ]
```

(continues on next page)

(continued from previous page)

```
        )

        # First, provide the args variable as our Twister command line arguments.
        # Then, catch the exit code in the sys_exit variable.
        with mock.patch.object(sys, "argv", [sys.argv[0]] + args), pytest.raises(
            SystemExit
        ) as sys_exit:
            # Execute the Twister call itself.
            self.loader.exec_module(self.twister_module)

        # Check whether the Twister call succeeded
        assert str(sys_exit.value) == "0"

        # Access to the test file output
        with open(os.path.join(out_path, "testplan.json")) as f:
            j = json.load(f)
        filtered_j = [
            (ts["platform"], ts["name"], tc["identifier"])
            for ts in j["testsuites"]
            for tc in ts["testcases"]
            if "reason" not in tc
        ]

        # Read stdout and stderr to out and err variables respectively
        out, err = capfd.readouterr()
        # Rewrite the captured buffers to stdout and stderr so the user can still read them
        sys.stdout.write(out)
        sys.stderr.write(err)

        # Test-relevant checks
        assert expected_tests == len(filtered_j)
```

Comparison with CLI

Test above runs the command

```
twister -i --outdir $OUTDIR -T $TEST_DATA/tests -y --level $LEVEL
--test-config $TEST_DATA/test_config.yaml -p qemu_x86 -p frdm_k64f
```

It presumes a CLI with the `zephyr-env.sh` or `zephyr-env.cmd` already run.

Such a test provides us with all the outputs we typically expect of a Twister run thanks to `importlib`'s `exec_module()`[1] . We can easily set up all flags that we expect from a Twister call via `args` variable[2] . We can check the standard output or stderr in `out` and `err` variables.

Beside the standard outputs, we can also investigate the file outputs, normally placed in `twister-out` directories. Most of the time, we will use the `out_path` fixture in conjunction with `--outdir` flag (L52) to keep test-generated files in temporary directories. Typical files read in blackbox tests are `testplan.json` , `twister.xml` and `twister.log` .

Other functionalities

Decorators

- `@pytest.mark.usefixtures('clear_log')`

[1] Take note of the `setup_class()` class function, which allows us to run `twister` python file as if it were called directly (bypassing the `__name__ == '__main__'` check).

[2] We advise you to keep the first section of `args` definition intact in almost all of your tests, as it is used for the common test setup.

  - allows us to use `clear_log` fixture from `conftest.py` . The fixture is to become `autouse` in the future. After that, this decorator can be removed.

- `@pytest.mark.parametrize('level, expected_tests', TESTDATA_X, ids=['smoke', 'acceptance'])`
  - this is an example of `pytest` 's test parametrization. Read up on it here. TESTDATAs are most often declared as class fields.
- `@mock.patch.object(TestPlan, 'TESTSUITE_FILENAME', testsuite_filename_mock)`
  - this decorator allows us to use only tests defined in the `test_data` and ignore the Zephyr testcases in the `tests` directory. **Note that all "test_data" tests use `test_data.yaml` as a filename, not `testcase.yaml` !** Read up on the `mock` library here.

Fixtures Blackbox tests use `pytest` 's fixtures, further reading on which is available here.

If you would like to add your own fixtures, consider whether they will be used in just one test file, or in many.

- If in many, create such a fixture in the scripts/tests/twister_blackbox/conftest.py file.
  - scripts/tests/twister_blackbox/conftest.py already contains some fixtures - take a look there for an example.
- If in just one, declare it in that file.
  - Consider using class fields instead - look at TESTDATAs for an example.

How do I...

Call Twister multiple times in one test? Sometimes we want to test something that requires prior Twister use. `--test-only` flag would be a typical example, as it is to be coupled with previous `--build-only` Twister call. How should we approach that?

If we just call the `importlib` 's `exec_module` two times, we will experience log duplication. `twister.log` will duplicate every line (triplicate if we call it three times, etc.) instead of overwriting the log or appending to the end of it.

It is caused by the use of logger module variables in the Twister files. Thus us executing the module again causes the loggers to have multiple handles.

To overcome this, between the calls you ought to use

```
capfd.readouterr()   # To remove output from the buffer
                     # Note that if you want output from all runs after each other,
                     # skip this line.
clear_log_in_test()  # To remove log duplication
```

2.12.4 Integration with pytest test framework

Please mind that integration of twister with pytest is still work in progress. Not every platform type is supported in pytest (yet). If you find any issue with the integration or have an idea for an improvement, please, let us know about it and open a GitHub issue/enhancement.

Introduction

Pytest is a python framework that *"makes it easy to write small, readable tests, and can scale to support complex functional testing for applications and libraries"* (https://docs.pytest.org/en/7.3.x/). Python is known for its free libraries and ease of using it for scripting. In addition, pytest utilizes the concept of plugins and fixtures, increasing its expendability and reusability. A pytest plugin *pytest-twister-harness* was introduced to provide an integration between pytest and twister, allowing Zephyr's community to utilize pytest functionality with keeping twister as the main framework.

Integration with twister

By default, there is nothing to be done to enable pytest support in twister. The plugin is developed as a part of Zephyr's tree. To enable install-less operation, twister first extends `PYTHONPATH` with path to this plugin, and then during pytest call, it appends the command with `-p twister_harness.plugin` argument. If one prefers to use the installed version of the plugin, they must add `--allow-installed-plugin` flag to twister's call.

Pytest-based test suites are discovered the same way as other twister tests, i.e., by a presence of test/sample.yaml. Inside, a keyword `harness` tells twister how to handle a given test. In the case of `harness: pytest`, most of twister workflow (test suites discovery, parallelization, building and reporting) remains the same as for other harnesses. The change happens during the execution step. The below picture presents a simplified overview of the integration.

If `harness: pytest` is used, twister delegates the test execution to pytest, by calling it as a subprocess. Required parameters (such as build directory, device to be used, etc.) are passed through a CLI command. When pytest is done, twister looks for a pytest report (results.xml) and sets the test result accordingly.

How to create a pytest test

An example folder containing a pytest test, application source code and Twister configuration .yaml file can look like the following:

```
test_foo/
├── pytest/
│   └── test_foo.py
├── src/
│   └── main.c
├── CMakeList.txt
├── prj.conf
└── testcase.yaml
```

An example of a pytest test is given at samples/subsys/testsuite/pytest/shell/pytest/test_shell.py. Using the configuration provided in the `testcase.yaml` file, Twister builds the application from `src` and then, if the .yaml file contains a `harness: pytest` entry, it calls pytest in a separate subprocess. A sample configuration file may look like this:

```
tests:
  some.foo.test:
    harness: pytest
    tags: foo
```

By default, pytest tries to look for tests in a `pytest` directory located next to a directory with binary sources. A keyword `pytest_root` placed under `harness_config` section in .yaml file can be used to point to other files, directories or subtests (more info *here*).

Pytest scans the given locations looking for tests, following its default discovery rules.

Passing extra arguments There are two ways for passing extra arguments to the called pytest subprocess:

1. From .yaml file, using `pytest_args` placed under `harness_config` section - more info *here*.
2. Through Twister command line interface as `--pytest-args` argument. This can be particularly useful when one wants to select a specific testcase from a test suite. For instance, one can use a command:

```
$ ./scripts/twister --platform native_sim -T samples/subsys/testsuite/pytest/shell \
-s samples/subsys/testsuite/pytest/shell/sample.pytest.shell \
--pytest-args='-k test_shell_print_version'
```

Fixtures

dut Give access to a *DeviceAdapter* type object, that represents Device Under Test. This fixture is the core of pytest harness plugin. It is required to launch DUT (initialize logging, flash device, connect serial etc). This fixture yields a device prepared according to the requested type (`native`, `qemu`, `hardware`, etc.). All types of devices share the same API. This allows for writing tests which are device-type-agnostic. Scope of this fixture is determined by the `pytest_dut_scope` keyword placed under `harness_config` section (more info *here*).

```
from twister_harness import DeviceAdapter

def test_sample(dut: DeviceAdapter):
   dut.readlines_until('Hello world')
```

shell Provide a *Shell* class object with methods used to interact with shell application. It calls `wait_for_promt` method, to not start scenario until DUT is ready. The shell fixture calls `dut` fixture, hence has access to all its methods. The `shell` fixture adds methods optimized for interactions with a shell. It can be used instead of `dut` for tests. Scope of this fixture is determined by the `pytest_dut_scope` keyword placed under `harness_config` section (more info *here*).

```
from twister_harness import Shell

def test_shell(shell: Shell):
   shell.exec_command('help')
```

mcumgr Sample fixture to wrap `mcumgr` command-line tool used to manage remote devices. More information about MCUmgr can be found here *MCUmgr*.

> **Note**
>
> This fixture requires the `mcumgr` available in the system PATH

Only selected functionality of MCUmgr is wrapped by this fixture. For example, here is a test with a fixture `mcumgr`

```
from twister_harness import DeviceAdapter, Shell, McuMgr

def test_upgrade(dut: DeviceAdapter, shell: Shell, mcumgr: McuMgr):
   # free the serial port for mcumgr
   dut.disconnect()
   # upload the signed image
   mcumgr.image_upload('path/to/zephyr.signed.bin')
```

(continues on next page)

(continued from previous page)

```
    # obtain the hash of uploaded image from the device
    second_hash = mcumgr.get_hash_to_test()
    # test a new upgrade image
    mcumgr.image_test(second_hash)
    # reset the device remotely
    mcumgr.reset_device()
    # continue test scenario, check version etc.
```

Classes

DeviceAdapter

class twister_harness.**DeviceAdapter**(*device_config: DeviceConfig*)

This class defines a common interface for all device types (hardware, simulator, QEMU) used in tests to gathering device output and send data to it.

launch() → None

Start by closing previously running application (no effect if not needed). Then, flash and run test application. Finally, start an internal reader thread capturing an output from a device.

connect(*retry_s: int = 0*) → None

Connect to device - allow for output gathering.

readline(*timeout: float | None = None*, *print_output: bool = True*) → str

Read line from device output. If timeout is not provided, then use base_timeout.

readlines(*print_output: bool = True*) → list[str]

Read all available output lines produced by device from internal buffer.

readlines_until(*regex: str | None = None*, *num_of_lines: int | None = None*, *timeout: float | None = None*, *print_output: bool = True*) → list[str]

Read available output lines produced by device from internal buffer until following conditions:

1. If regex is provided - read until regex regex is found in read line (or until timeout).
2. If num_of_lines is provided - read until number of read lines is equal to num_of_lines (or until timeout).
3. If none of above is provided - return immediately lines collected so far in internal buffer.

If timeout is not provided, then use base_timeout.

write(*data: bytes*) → None

Write data bytes to device.

disconnect() → None

Disconnect device - block output gathering.

close() → None

Disconnect, close device and close reader thread.

Shell

class twister_harness.**Shell**(*device:* DeviceAdapter, *prompt: str = 'uart:~$'*, *timeout: float | None = None*)

Helper class that provides methods used to interact with shell application.

`exec_command`(*command: str*, *timeout: float | None = None*, *print_output: bool = True*) → list[str]

Send shell command to a device and return response. Passed command is extended by double enter sings - first one to execute this command on a device, second one to receive next prompt what is a signal that execution was finished. Method returns printout of the executed command.

`wait_for_prompt`(*timeout: float | None = None*) → bool

Send every 0.5 second "enter" command to the device until shell prompt statement will occur (return True) or timeout will be exceeded (return False).

Examples of pytest tests in the Zephyr project

- pytest_shell
- MCUmgr tests - tests/boot/with_mcumgr
- LwM2M tests - tests/net/lib/lwm2m/interop
- GDB stub tests - tests/subsys/debug/gdbstub

FAQ

How to flash/run application only once per pytest session?

`dut` is a fixture responsible for flashing/running application. By default, its scope is set as `function`. This can be changed by adding to .yaml file `pytest_dut_scope` keyword placed under `harness_config` section:

```
harness: pytest
harness_config:
   pytest_dut_scope: session
```

More info can be found *here*.

How to run only one particular test from a python file?

This can be achieved in several ways. In .yaml file it can be added using a `pytest_root` entry placed under `harness_config` with list of tests which should be run:

```
harness: pytest
harness_config:
   pytest_root:
      - "pytest/test_shell.py::test_shell_print_help"
```

Particular tests can be also chosen by pytest `-k` option (more info about pytest keyword filter can be found here). It can be applied by adding `-k` filter in `pytest_args` in .yaml file:

```
harness: pytest
harness_config:
   pytest_args:
      - "-k test_shell_print_help"
```

or by adding it to Twister command overriding parameters from the .yaml file:

```
$ ./scripts/twister ... --pytest-args='-k test_shell_print_help'
```

How to get information about used device type in test?

This can be taken from `dut` fixture (which represents *DeviceAdapter* object):

```
device_type: str = dut.device_config.type
if device_type == 'hardware':
    ...
elif device_type == 'native':
    ...
```

How to rerun locally pytest tests without rebuilding application by Twister?

This can be achieved by running Twister once again with `--test-only` argument added to Twister command. Another way is running Twister with highest verbosity level (`-vv`) and then copy-pasting from logs command dedicated for spawning pytest (log started by `Running pytest command: ...`).

Is this possible to run pytest tests in parallel?

Basically `pytest-harness-plugin` wasn't written with intention of running pytest tests in parallel. Especially those one dedicated for hardware. There was assumption that parallelization of tests is made by Twister, and it is responsible for managing available sources (jobs and hardwares). If anyone is interested in doing this for some reasons (for example via pytest-xdist plugin) they do so at their own risk.

Limitations

- Not every platform type is supported in the plugin (yet).

2.12.5 Generating coverage reports

With Zephyr, you can generate code coverage reports to analyze which parts of the code are covered by a given test or application.

You can do this in two ways:

- In a real embedded target or QEMU, using Zephyr's gcov integration
- Directly in your host computer, by compiling your application targeting the POSIX architecture

Test coverage reports in embedded devices or QEMU

Overview GCC GCOV is a test coverage program used together with the GCC compiler to analyze and create test coverage reports for your programs, helping you create more efficient, faster running code and discovering untested code paths

In Zephyr, gcov collects coverage profiling data in RAM (and not to a file system) while your application is running. Support for gcov collection and reporting is limited by available RAM size and so is currently enabled only for QEMU emulation of embedded targets.

Details There are 2 parts to enable this feature. The first is to enable the coverage for the device and the second to enable in the test application. As explained earlier the code coverage with gcov is a function of RAM available. Therefore ensure that the device has enough RAM when enabling the coverage for it. For example a small device like frdm_k64f can run a simple test application but the more complex test cases which consume more RAM will crash when coverage is enabled.

To enable the device for coverage, select `CONFIG_HAS_COVERAGE_SUPPORT` in the Kconfig.board file.

To report the coverage for the particular test application set `CONFIG_COVERAGE`.

Steps to generate code coverage reports These steps will produce an HTML coverage report for a single application.

1. Build the code with CONFIG_COVERAGE=y.

   ```
   west build -b mps2/an385 -- -DCONFIG_COVERAGE=y -DCONFIG_COVERAGE_DUMP=y
   ```

2. Capture the emulator output into a log file. You may need to terminate the emulator with `Ctrl-A X` for this to complete after the coverage dump has been printed:

   ```
   ninja -Cbuild run | tee log.log
   ```

   or

   ```
   ninja -Cbuild run | tee log.log
   ```

3. Generate the gcov `.gcda` and `.gcno` files from the log file that was saved:

   ```
   $ python3 scripts/gen_gcov_files.py -i log.log
   ```

4. Find the gcov binary placed in the SDK. You will need to pass the path to the gcov binary for the appropriate architecture when you later invoke `gcovr`:

   ```
   $ find $ZEPHYR_SDK_INSTALL_DIR -iregex ".*gcov"
   ```

5. Create an output directory for the reports:

   ```
   $ mkdir -p gcov_report
   ```

6. Run `gcovr` to get the reports:

   ```
   $ gcovr -r $ZEPHYR_BASE . --html -o gcov_report/coverage.html --html-details --gcov-
   ↪executable <gcov_path_in_SDK>
   ```

Coverage reports using the POSIX architecture

When compiling for the POSIX architecture, you utilize your host native tooling to build a native executable which contains your application, the Zephyr OS, and some basic HW emulation.

That means you can use the same tools you would while developing any other desktop application.

To build your application with gcc's gcov, simply set `CONFIG_COVERAGE` before compiling it. When you run your application, `gcov` coverage data will be dumped into the respective `gcda` and `gcno` files. You may postprocess these with your preferred tools. For example:

```
west build -b native_sim samples/hello_world -- -DCONFIG_COVERAGE=y
```

```
$ ./build/zephyr/zephyr.exe
# Press Ctrl+C to exit
lcov --capture --directory ./ --output-file lcov.info -q --rc lcov_branch_coverage=1
genhtml lcov.info --output-directory lcov_html -q --ignore-errors source --branch-coverage -
↪-highlight --legend
```

Note

You need a recent version of lcov (at least 1.14) with support for intermediate text format. Such packages exist in recent Linux distributions.

Alternatively, you can use gcovr (at least version 4.2).

Coverage reports using Twister

Zephyr's *twister script* can automatically generate a coverage report from the tests which were executed. You just need to invoke it with the `--coverage` command line option.

For example, you may invoke:

```
$ twister --coverage -p qemu_x86 -T tests/kernel
```

or:

```
$ twister --coverage -p native_sim -T tests/bluetooth
```

which will produce `twister-out/coverage/index.html` report as well as the coverage data collected by `gcovr` tool in `twister-out/coverage.json`.

Other reports might be chosen with `--coverage-tool` and `--coverage-formats` command line options.

The process differs for unit tests, which are built with the host toolchain and require a different board:

```
$ twister --coverage -p unit_testing -T tests/unit
```

which produces a report in the same location as non-unit testing.

Using different toolchains Twister looks at the environment variable `ZEPHYR_TOOLCHAIN_VARIANT` to check which gcov tool to use by default. The following are used as the default for the Twister `--gcov-tool` argument default:

Toolchain	`--gcov-tool` value
host	`gcov`
llvm	`llvm-cov gcov`
zephyr	`gcov`

2.12.6 BabbleSim

BabbleSim and Zephyr

In the Zephyr project we use the Babblesim simulator to test some of the Zephyr radio protocols, including the BLE stack, 802.15.4, and some of the networking stack.

BabbleSim is a physical layer simulator, which in combination with the Zephyr bsim boards can be used to simulate a network of BLE and 15.4 devices. When we build Zephyr targeting a bsim board we produce a Linux executable, which includes the application, Zephyr OS, and models of the HW.

When there is radio activity, this Linux executable will connect to the BabbleSim Phy simulation to simulate the radio channel.

In the BabbleSim documentation you can find more information on how to get and build the simulator. In the nrf52_bsim, nrf5340bsim, and nrf54l15bsim boards documentation you can find more information about how to build Zephyr targeting these particular boards, and a few examples.

Types of tests

Tests without radio activity: bsim tests with twister The bsim boards can be used without radio activity, and in that case, it is not necessary to connect them to a physical layer simulation. Thanks to this, these target boards can be used just like native_sim with *twister*, to run all standard Zephyr twister tests, but with models of a real SOC HW, and their drivers.

Tests with radio activity When there is radio activity, BabbleSim tests require at the very least a physical layer simulation running, and most, more than 1 simulated device. Due to this, these tests are not build and run with twister, but with a dedicated set of tests scripts.

These tests are kept in the `tests/bsim/` folder. The `compile.sh` and `run_parallel.sh` scripts contained in that folder are used by the CI system to build the needed images and execute these tests in batch.

See sections below for more information about how to build and run them, as well as the conventions they follow.

There are two main sets of tests:

- Self checking embedded application/tests: In which some of the simulated devices applications are built with some checks which decide if the test is passing or failing. These embedded applications tests use the bs_tests system to report the pass or failure, and in many cases to build several tests into the same binary.
- Test using the EDTT tool, in which a EDTT (python) test controls the embedded applications over an RPC mechanism, and decides if the test passes or not. Today these tests include a very significant subset of the BT qualification test suite.

More information about how different tests types relate to BabbleSim and the bsim boards can be found in the bsim boards tests section.

Test coverage and BabbleSim

As the nrf52_bsim and nrf5340bsim, and nrf54l15bsim boards are based on the POSIX architecture, you can easily collect test coverage information.

You can use the script tests/bsim/generate_coverage_report.sh to generate an html coverage report from tests.

Check *the page on coverage generation* for more info.

Building and running the tests

See the nrf52_bsim page for setting up the simulator.

The scripts also expect a few environment variables to be set. For example, from Zephyr's root folder, you can run:

```
# Build all the tests
${ZEPHYR_BASE}/tests/bsim/compile.sh

# Run them (in parallel)
RESULTS_FILE=${ZEPHYR_BASE}/myresults.xml \
   SEARCH_PATH=${ZEPHYR_BASE}/tests/bsim \
      ${ZEPHYR_BASE}/tests/bsim/run_parallel.sh
```

Or to build and run only a specific subset, e.g. host advertising tests:

```
# Build the Bluetooth host advertising tests
${ZEPHYR_BASE}/tests/bsim/bluetooth/host/adv/compile.sh

# Run them (in parallel)
RESULTS_FILE=${ZEPHYR_BASE}/myresults.xml \
   SEARCH_PATH=${ZEPHYR_BASE}/tests/bsim/bluetooth/host/adv \
      ${ZEPHYR_BASE}/tests/bsim/run_parallel.sh
```

Check the `run_parallel.sh` help for more options and examples on how to use this script to run the tests in batch.

After building the tests' required binaries you can run a test directly using its individual test script.

For example you can build the required binaries for the networking tests with

```
WORK_DIR=${ZEPHYR_BASE}/bsim_out ${ZEPHYR_BASE}/tests/bsim/net/compile.sh
```

and then directly run one of the tests:

```
${ZEPHYR_BASE}/tests/bsim/net/sockets/echo_test/tests_scripts/echo_test_802154.sh
```

Conventions

Test code See the Bluetooth sample test for conventions that apply to test code.

Build scripts The build scripts `compile.sh` simply build all the required test and sample applications for the tests' scripts placed in the subfolders below.

This build scripts use the common compile.source which provide a function (compile) which calls cmake and ninja with the provided application, configuration and overlay files.

To speed up compilation for users interested only in a subset of tests, several compile scripts exist in several subfolders, where the upper ones call into the lower ones.

Note that cmake and ninja are used directly instead of the `west build` wrapper as west is not required, and some Zephyr users do not use or have west, but still use the build and tests scripts.

Test scripts Please follow the existing conventions and do not design one-off bespoke runners (e.g. a python script, or another shell abstraction).

The rationale is that it is easier and faster for the maintainers to perform tree-wide updates for build system or compatibility changes if the tests are run in the same manner, with the same variables, etc..

If you have a good idea for improving your test script, please make a PR changing *all* the test scripts in order to benefit everyone and conserve homogeneity. You can of course discuss it first in an RFC issue or on the babblesim discord channel.

Scripts starting with an underscore (_) are not automatically discovered and run. They can serve as either helper functions for the main script, or can be used for local development utilities, e.g. building and running tests locally, debugging, etc..

Here are the conventions:

- Each test is defined by a shell script with the extension `.sh`, in a subfolder called `test_scripts/`.
- It is recommended to run a single test per script file. It allows for better parallelization of the runs in CI.
- Scripts expect that the binaries they require are already built. They should not compile binaries.
- Scripts will spawn the processes for every simulated device and the physical layer simulation.
- Scripts must return 0 to the invoking shell if the test passes, and not 0 if the test fails.
- Each test must have a unique simulation id, to enable running different tests in parallel.
- Neither the scripts nor the images should modify the workstation filesystem content beyond the `${BSIM_OUT_PATH}/results/<simulation_id>/` or `/tmp/` folders. That is, they should not leave stray files behind.
- Tests that require several consecutive simulations (e.g, if simulating a device pairing, powering off, and powering up after as a new simulation) should use separate simulation ids for each simulation segment, ensuring that the radio activity of each segment can be inspected a posteriori.
- Avoid overly long tests. If the test takes over 20 seconds of runtime, consider if it is possible to split it in several separate tests.
- If the test takes over 5 seconds, set `EXECUTE_TIMEOUT` to a value that is at least 5 times bigger than the measured run-time.
- Do not set `EXECUTE_TIMEOUT` to a value lower than the default.
- Tests should not be overly verbose: less than a hundred lines are expected on the outputs. Do make use of `LOG_DBG()` extensively, but don't enable the `DBG` log level by default.

2.12.7 ZTest Deprecated APIs

Ztest is currently being migrated to a new API, this documentation provides information about the deprecated APIs which will eventually be removed. See *Test Framework* for the new API. Similarly, ZTest's mocking framework is also deprecated (see *Mocking via FFF*).

Quick start - Unit testing

Ztest can be used for unit testing. This means that rather than including the entire Zephyr OS for testing a single function, you can focus the testing efforts into the specific module in question. This will speed up testing since only the module will have to be compiled in, and the tested functions will be called directly.

Since you won't be including basic kernel data structures that most code depends on, you have to provide function stubs in the test. Ztest provides some helpers for mocking functions, as demonstrated below.

In a unit test, mock objects can simulate the behavior of complex real objects and are used to decide whether a test failed or passed by verifying whether an interaction with an object occurred, and if required, to assert the order of that interaction.

Best practices for declaring the test suite *twister* and other validation tools need to obtain the list of subcases that a Zephyr *ztest* test image will expose.

Rationale

This all is for the purpose of traceability. It's not enough to have only a semaphore test project. We also need to show that we have testpoints for all APIs and functionality, and we trace back to documentation of the API, and functional requirements.

The idea is that test reports show results for every sub-testcase as passed, failed, blocked, or skipped. Reporting on only the high-level test project level, particularly when tests do too many things, is too vague.

There exist two alternatives to writing tests. The first, and more verbose, approach is to directly declare and run the test suites. Here is a generic template for a test showing the expected use of `ztest_test_suite()`:

```
#include <zephyr/ztest.h>

extern void test_sometest1(void);
extern void test_sometest2(void);
#ifndef CONFIG_WHATEVER              /* Conditionally skip test_sometest3 */
void test_sometest3(void)
{
     ztest_test_skip();
}
#else
extern void test_sometest3(void);
#endif
extern void test_sometest4(void);
...

void test_main(void)
{
     ztest_test_suite(common,
                      ztest_unit_test(test_sometest1),
                      ztest_unit_test(test_sometest2),
                      ztest_unit_test(test_sometest3),
                      ztest_unit_test(test_sometest4)
                );
     ztest_run_test_suite(common);
}
```

Alternatively, it is possible to split tests across multiple files using `ztest_register_test_suite()` which bypasses the need for `extern`:

```
#include <zephyr/ztest.h>

void test_sometest1(void) {
      zassert_true(1, "true");
}

ztest_register_test_suite(common, NULL,
                          ztest_unit_test(test_sometest1)
                          );
```

The above sample simple registers the test suite and uses a NULL pragma function (more on that later). It is important to note that the test suite isn't directly run in this file. Instead two alternatives exist for running the suite. First, if to do nothing. A default test_main function is provided by ztest. This is the preferred approach if the test doesn't involve a state and doesn't require use of the pragma.

In cases of an integration test it is possible that some general state needs to be set between test suites. This can be thought of as a state diagram in which test_main simply goes through various actions that modify the board's state and different test suites need to run. This is achieved in the following:

```
#include <zephyr/ztest.h>

struct state {
	bool is_hibernating;
	bool is_usb_connected;
}

static bool pragma_always(const void *state)
{
	return true;
}

static bool pragma_not_hibernating_not_connected(const void *s)
{
	struct state *state = s;
	return !state->is_hibernating && !state->is_usb_connected;
}

static bool pragma_usb_connected(const void *s)
{
	return ((struct state *)s)->is_usb_connected;
}

ztest_register_test_suite(baseline, pragma_always,
                          ztest_unit_test(test_case0));
ztest_register_test_suite(before_usb, pragma_not_hibernating_not_connected,
                          ztest_unit_test(test_case1),
                          ztest_unit_test(test_case2));
ztest_register_test_suite(with_usb, pragma_usb_connected,,
                          ztest_unit_test(test_case3),
                          ztest_unit_test(test_case4));

void test_main(void)
{
	struct state state;

	/* Should run `baseline` test suite only. */
	ztest_run_registered_test_suites(&state);

	/* Simulate power on and update state. */
	emulate_power_on();
	/* Should run `baseline` and `before_usb` test suites. */
	ztest_run_registered_test_suites(&state);

	/* Simulate plugging in a USB device. */
	emulate_plugging_in_usb();
	/* Should run `baseline` and `with_usb` test suites. */
	ztest_run_registered_test_suites(&state);

	/* Verify that all the registered test suites actually ran. */
	ztest_verify_all_registered_test_suites_ran();
}
```

For *twister* to parse source files and create a list of subcases, the declarations of `ztest_test_suite()` and `ztest_register_test_suite()` must follow a few rules:

- one declaration per line
- conditional execution by using *ztest_test_skip()*

What to avoid:

- packing multiple testcases in one source file

```
void test_main(void)
{
#ifdef TEST_feature1
        ztest_test_suite(feature1,
                         ztest_unit_test(test_1a),
                         ztest_unit_test(test_1b),
                         ztest_unit_test(test_1c)
                         );
        ztest_run_test_suite(feature1);
#endif

#ifdef TEST_feature2
        ztest_test_suite(feature2,
                         ztest_unit_test(test_2a),
                         ztest_unit_test(test_2b)
                         );
        ztest_run_test_suite(feature2);
#endif
}
```

- Do not use `#if`

```
        ztest_test_suite(common,
                         ztest_unit_test(test_sometest1),
                         ztest_unit_test(test_sometest2),
#ifdef CONFIG_WHATEVER
                         ztest_unit_test(test_sometest3),
#endif
                         ztest_unit_test(test_sometest4),
        ...
```

- Do not add comments on lines with a call to *ztest_unit_test()*:

```
ztest_test_suite(common,
                 ztest_unit_test(test_sometest1),
                 ztest_unit_test(test_sometest2) /* will fail */,
/* will fail! */ ztest_unit_test(test_sometest3),
                 ztest_unit_test(test_sometest4),
...
```

- Do not define multiple definitions of unit / user unit test case per line

```
ztest_test_suite(common,
                 ztest_unit_test(test_sometest1), ztest_unit_test(test_sometest2),
                 ztest_unit_test(test_sometest3),
                 ztest_unit_test(test_sometest4),
...
```

Other questions:

- Why not pre-scan with CPP and then parse? or post scan the ELF file?

  If C pre-processing or building fails because of any issue, then we won't be able to tell the subcases.

- Why not declare them in the YAML testcase description?

  A separate testcase description file would be harder to maintain than just keeping the information in the test source files themselves – only one file to update when changes are made eliminates duplication.

Mocking

These functions allow abstracting callbacks and related functions and controlling them from specific tests. You can enable the mocking framework by setting `CONFIG_ZTEST_MOCKING` to "y" in the configuration file of the test. The amount of concurrent return values and expected parameters is limited by `CONFIG_ZTEST_PARAMETER_COUNT`.

Here is an example for configuring the function `expect_two_parameters` to expect the values `a=2` and `b=3`, and telling `returns_int` to return 5:

```
#include <zephyr/ztest.h>

static void expect_two_parameters(int a, int b)
{
        ztest_check_expected_value(a);
        ztest_check_expected_value(b);
}

static void parameter_tests(void)
{
        ztest_expect_value(expect_two_parameters, a, 2);
        ztest_expect_value(expect_two_parameters, b, 3);
        expect_two_parameters(2, 3);
}

static int returns_int(void)
{
        return ztest_get_return_value();
}

static void return_value_tests(void)
{
        ztest_returns_value(returns_int, 5);
        zassert_equal(returns_int(), 5, NULL);
}

void test_main(void)
{
        ztest_test_suite(mock_framework_tests,
                ztest_unit_test(parameter_test),
                ztest_unit_test(return_value_test)
        );

        ztest_run_test_suite(mock_framework_tests);
}
```

group **ztest_mock**

This module provides simple mocking functions for unit testing.

These need CONFIG_ZTEST_MOCKING=y.

Defines

`ztest_expect_value`(func, param, value)

Tell function *func* to expect the value *value* for *param*.

When using *ztest_check_expected_value()*, tell that the value of *param* should be *value*. The value will internally be stored as an `uintptr_t`.

Parameters

- `func` – Function in question
- `param` – Parameter for which the value should be set
- `value` – Value for *param*

`ztest_check_expected_value`(param)

If *param* doesn't match the value set by *ztest_expect_value()*, fail the test.

This will first check that does *param* have a value to be expected, and then checks whether the value of the parameter is equal to the expected value. If either of these checks fail, the current test will fail. This must be called from the called function.

Parameters

- `param` – Parameter to check

`ztest_expect_data`(func, param, data)

Tell function *func* to expect the data *data* for *param*.

When using *ztest_check_expected_data()*, the data pointed to by *param* should be same *data* in this function. Only data pointer is stored by this function, so it must still be valid when ztest_check_expected_data is called.

Parameters

- `func` – Function in question
- `param` – Parameter for which the data should be set
- `data` – pointer for the data for parameter *param*

`ztest_check_expected_data`(param, length)

If data pointed by *param* don't match the data set by *ztest_expect_data()*, fail the test.

This will first check that *param* is expected to be null or non-null and then check whether the data pointed by parameter is equal to expected data. If either of these checks fail, the current test will fail. This must be called from the called function.

Parameters

- `param` – Parameter to check
- `length` – Length of the data to compare

`ztest_return_data`(func, param, data)

Tell function *func* to return the data *data* for *param*.

When using *ztest_return_data()*, the data pointed to by *param* should be same *data* in this function. Only data pointer is stored by this function, so it must still be valid when ztest_copy_return_data is called.

Parameters

- `func` – Function in question
- `param` – Parameter for which the data should be set
- `data` – pointer for the data for parameter *param*

`ztest_copy_return_data`(param, length)

Copy the data set by ztest_return_data to the memory pointed by *param*.

This will first check that *param* is not null and then copy the data. This must be called from the called function.

Parameters

- `param` – Parameter to return data for
- `length` – Length of the data to return

`ztest_returns_value`(func, value)

Tell *func* that it should return *value*.

Parameters

- `func` – Function that should return *value*
- `value` – Value to return from *func*

`ztest_get_return_value`()

Get the return value for current function.

The return value must have been set previously with *ztest_returns_value()*. If no return value exists, the current test will fail.

Returns

The value the current function should return

`ztest_get_return_value_ptr`()

Get the return value as a pointer for current function.

The return value must have been set previously with *ztest_returns_value()*. If no return value exists, the current test will fail.

Returns

The value the current function should return as a `void *`

2.13 Static Code Analysis (SCA)

Support for static code analysis tools in Zephyr is possible through CMake.

The build setting `ZEPHYR_SCA_VARIANT` can be used to specify the SCA tool to use. `ZEPHYR_SCA_VARIANT` is also supported as *environment variable*.

Use `-DZEPHYR_SCA_VARIANT=<tool>`, for example `-DZEPHYR_SCA_VARIANT=sparse` to enable the static analysis tool `sparse`.

2.13.1 SCA Tool infrastructure

Support for an SCA tool is implemented in a file:*sca.cmake* file. The file:*sca.cmake* must be placed under file:*<SCA_ROOT>/cmake/sca/<tool>/sca.cmake*. Zephyr itself is always added as an `SCA_ROOT` but the build system offers the possibility to add additional folders to the `SCA_ROOT` setting.

You can provide support for out of tree SCA tools by creating the following structure:

```
<sca_root>/                 # Custom SCA root
└── cmake/
    └── sca/
        └── <tool>/         # Name of SCA tool, this is the value given to ZEPHYR_SCA_
```

(continues on next page)

(continued from previous page)

```
↪VARIANT
            └── sca.cmake   # CMake code that configures the tool to be used with Zephyr
```

To add `foo` under `/path/to/my_tools/cmake/sca` create the following structure:

```
/path/to/my_tools
         └── cmake/
             └── sca/
                 └── foo/
                     └── sca.cmake
```

To use `foo` as SCA tool you must then specify `-DZEPHYR_SCA_VARIANT=foo`.

Remember to add `/path/to/my_tools` to **SCA_ROOT**.

SCA_TOOL can be set as a regular CMake setting using `-DSCA_ROOT=<sca_root>`, or added by a Zephyr module in its `module.yml` file, see *Zephyr Modules - Build settings*

2.13.2 Native SCA Tool support

The following is a list of SCA tools natively supported by Zephyr build system.

CodeChecker support

CodeChecker is a static analysis infrastructure. It executes analysis tools available on the build system, such as Clang-Tidy, Clang Static Analyzer and Cppcheck. Refer to the analyzer's websites for installation instructions.

Installing CodeChecker CodeChecker itself is a python package available on pypi.

```
pip install codechecker
```

Running with CodeChecker To run CodeChecker, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=codechecker` parameter, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=codechecker
```

Configuring CodeChecker To configure CodeChecker or analyzers used, arguments can be passed using the `CODECHECKER_ANALYZE_OPTS` parameter, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=codechecker \
-DCODECHECKER_ANALYZE_OPTS="--config;$CODECHECKER_CONFIG_FILE;--timeout;60"
```

Storing CodeChecker results If a CodeChecker server is active the results can be uploaded and stored for tracking purposes. Storing is done using the optional `CODECHECKER_STORE=y` or `CODECHECKER_STORE_OPTS="arg;list"` parameters, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=codechecker \
-DCODECHECKER_STORE_OPTS="--name;build;--url;localhost:8001/Default"
```

> **Note**
>
> If `--name` isn't passed to either `CODECHECKER_ANALYZE_OPTS` or `CODECHECKER_STORE_OPTS`, the default `zephyr` is used.

Exporting CodeChecker reports Optional reports can be generated using the CodeChecker results, when passing a `-DCODECHECKER_EXPORT=<type>` parameter. Allowed types are: `html`, `json`, `codeclimate`, `gerrit`, `baseline`. Multiple types can be passed as comma-separated arguments.

Optional parser configuration arguments can be passed using the `CODECHECKER_PARSE_OPTS` parameter, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=codechecker \
-DCODECHECKER_EXPORT=html,json -DCODECHECKER_PARSE_OPTS="--trim-path-prefix;$PWD"
```

Failing the build on CodeChecker issues By default, CodeChecker identified issues will not fail the build, only generate a report. To fail the build if any issues are found (for example, for use in CI), pass the `CODECHECKER_PARSE_EXIT_STATUS=y` parameter, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=codechecker \
-DCODECHECKER_PARSE_EXIT_STATUS=y
```

Sparse support

Sparse is a static code analysis tool. Apart from performing common code analysis tasks it also supports an `address_space` attribute, which allows introduction of distinct address spaces in C code with subsequent verification that pointers to different address spaces do not get confused. Additionally it supports a `force` attribute which should be used to cast pointers between different address spaces. At the moment Zephyr introduces a single custom address space `__cache` used to identify pointers from the cached address range on the Xtensa architecture. This helps identify cases where cached and uncached addresses are confused.

Running with sparse To run a sparse verification build *west build* should be called with a `-DZEPHYR_SCA_VARIANT=sparse` parameter, e.g.

```
west build -d hello -b intel_adsp/cavs25 zephyr/samples/hello_world -- -DZEPHYR_SCA_
↪VARIANT=sparse
```

GCC static analysis support

Static analysis was introduced in GCC 10 and it is enabled with the option `-fanalyzer`. This option performs a much more expensive and thorough analysis of the code than traditional warnings.

Run GCC static analysis To run GCC static analysis, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=gcc` parameter, e.g.

```
west build -b qemu_x86 samples/userspace/hello_world_user -- -DZEPHYR_SCA_VARIANT=gcc
```

Parasoft C/C++test support

Parasoft C/C++test is a software testing and static analysis tool for C and C++. It is a commercial software and you must acquire a commercial license to use it.

Documentation of C/C++test can be found at https://docs.parasoft.com/. Please refer to the documentation for how to use it.

Generating Build Data Files To use C/C++test, `cpptestscan` must be found in your *PATH* environment variable. And *west build* should be called with a `-DZEPHYR_SCA_VARIANT=cpptest` parameter, e.g.

```
west build -b qemu_cortex_m3 zephyr/samples/hello_world -- -DZEPHYR_SCA_VARIANT=cpptest
```

A `.bdf` file will be generated as `build/sca/cpptest/cpptestscan.bdf`.

Generating a report file Please refer to Parasoft C/C++test documentation for more details.

To import and generate a report file, something like the following should work.

```
cpptestcli -data out -localsettings local.conf -bdf build/sca/cpptest/cpptestscan.bdf -
↪config "builtin://Recommended Rules" -report out/report
```

You might need to set `bdf.import.c.compiler.exec`, `bdf.import.cpp.compiler.exec`, and `bdf.import.linker.exec` to the toolchain *west build* used.

2.14 Toolchains

Guides on how to set up toolchains for Zephyr development.

2.14.1 Zephyr SDK

The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr's supported architectures. It also includes additional host tools, such as custom QEMU and OpenOCD.

Use of the Zephyr SDK is highly recommended and may even be required under certain conditions (for example, running tests in QEMU for some architectures).

Supported architectures

The Zephyr SDK supports the following target architectures:

- ARC (32-bit and 64-bit; ARCv1, ARCv2, ARCv3)
- ARM (32-bit and 64-bit; ARMv6, ARMv7, ARMv8; A/R/M Profiles)
- MIPS (32-bit and 64-bit)
- Nios II
- RISC-V (32-bit and 64-bit; RV32I, RV32E, RV64I)
- x86 (32-bit and 64-bit)
- Xtensa

Installation bundle and variables

The Zephyr SDK bundle supports all major operating systems (Linux, macOS and Windows) and is delivered as a compressed file. The installation consists of extracting the file and running the included setup script. Additional OS-specific instructions are described in the sections below.

If no toolchain is selected, the build system looks for Zephyr SDK and uses the toolchain from there. You can enforce this by setting the environment variable *ZEPHYR_TOOLCHAIN_VARIANT* to `zephyr`.

If you install the Zephyr SDK outside any of the default locations (listed in the operating system specific instructions below) and you want automatic discovery of the Zephyr SDK, then you must register the Zephyr SDK in the CMake package registry by running the setup script. If you decide not to register the Zephyr SDK in the CMake registry, then the *ZEPHYR_SDK_INSTALL_DIR* can be used to point to the Zephyr SDK installation directory.

You can also set *ZEPHYR_SDK_INSTALL_DIR* to point to a directory containing multiple Zephyr SDKs, allowing for automatic toolchain selection. For example, you can set `ZEPHYR_SDK_INSTALL_DIR` to `/company/tools`, where the `company/tools` folder contains the following subfolders:

- `/company/tools/zephyr-sdk-0.13.2`
- `/company/tools/zephyr-sdk-a.b.c`
- `/company/tools/zephyr-sdk-x.y.z`

This allows the Zephyr build system to choose the correct version of the SDK, while allowing multiple Zephyr SDKs to be grouped together at a specific path.

Zephyr SDK version compatibility

In general, the Zephyr SDK version referenced in this page should be considered the recommended version for the corresponding Zephyr version.

For the full list of compatible Zephyr and Zephyr SDK versions, refer to the Zephyr SDK Version Compatibility Matrix.

Zephyr SDK installation

Note

You can change `0.16.8` to another version in the instructions below if needed; the Zephyr SDK Releases page contains all available SDK releases.

Note

If you want to uninstall the SDK, you may simply remove the directory where you installed it.

Ubuntu

1. Download and verify the Zephyr SDK bundle:

```
cd ~
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.8/
↪zephyr-sdk-0.16.8_linux-x86_64.tar.xz
```

```
wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.
↪16.8/sha256.sum | shasum --check --ignore-missing
```

If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace `x86_64` with `aarch64` in order to download the 64-bit ARM Linux SDK.

2. Extract the Zephyr SDK bundle archive:

```
tar xvf zephyr-sdk-0.16.8_linux-x86_64.tar.xz
```

> **Note**
>
> It is recommended to extract the Zephyr SDK bundle at one of the following locations:
>
> - `$HOME`
> - `$HOME/.local`
> - `$HOME/.local/opt`
> - `$HOME/bin`
> - `/opt`
> - `/usr/local`
>
> The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `$HOME`, the resulting installation path will be `$HOME/zephyr-sdk-<version>`.

3. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-0.16.8
./setup.sh
```

> **Note**
>
> You only need to run the setup script once after extracting the Zephyr SDK bundle.
>
> You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

4. Install udev rules, which allow you to flash most Zephyr boards as a regular user:

```
sudo cp ~/zephyr-sdk-0.16.8/sysroots/x86_64-pokysdk-linux/usr/share/openocd/
↪contrib/60-openocd.rules /etc/udev/rules.d
sudo udevadm control --reload
```

macOS

1. Download and verify the Zephyr SDK bundle:

```
cd ~
curl -L -O https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.
↪16.8/zephyr-sdk-0.16.8_macos-x86_64.tar.xz
curl -L https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.
↪8/sha256.sum | shasum --check --ignore-missing
```

If your host architecture is 64-bit ARM (Apple Silicon), replace `x86_64` with `aarch64` in order to download the 64-bit ARM macOS SDK.

2. Extract the Zephyr SDK bundle archive:

```
tar xvf zephyr-sdk-0.16.8_macos-x86_64.tar.xz
```

> **Note**
>
> It is recommended to extract the Zephyr SDK bundle at one of the following locations:
>
> - `$HOME`
> - `$HOME/.local`
> - `$HOME/.local/opt`
> - `$HOME/bin`
> - `/opt`
> - `/usr/local`
>
> The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `$HOME`, the resulting installation path will be `$HOME/zephyr-sdk-<version>`.

3. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-0.16.8
./setup.sh
```

> **Note**
>
> You only need to run the setup script once after extracting the Zephyr SDK bundle.
>
> You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

Windows

1. Open a `cmd.exe` terminal window **as a regular user**
2. Download the Zephyr SDK bundle:

```
cd %HOMEPATH%
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.8/
↪zephyr-sdk-0.16.8_windows-x86_64.7z
```

3. Extract the Zephyr SDK bundle archive:

```
7z x zephyr-sdk-0.16.8_windows-x86_64.7z
```

> **Note**
>
> It is recommended to extract the Zephyr SDK bundle at one of the following locations:
>
> - `%HOMEPATH%`
> - `%PROGRAMFILES%`
>
> The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `%HOMEPATH%`, the resulting installation path will be `%HOMEPATH%\zephyr-sdk-<version>`.

4. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-0.16.8
setup.cmd
```

> **Note**
>
> You only need to run the setup script once after extracting the Zephyr SDK bundle.
>
> You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

2.14.2 Arm Compiler 6

1. Download and install a development suite containing the Arm Compiler 6 for your operating system.
2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `armclang`.
   - Set `ARMCLANG_TOOLCHAIN_PATH` to the toolchain installation directory.
3. The Arm Compiler 6 needs the `ARMLMD_LICENSE_FILE` environment variable to point to your license file or server.

For example:

```
# Linux, macOS, license file:
export ARMLMD_LICENSE_FILE=/<path>/license_armds.dat
# Linux, macOS, license server:
export ARMLMD_LICENSE_FILE=8224@myserver
```

```
# Windows, license file:
set ARMLMD_LICENSE_FILE=c:\<path>\license_armds.dat
# Windows, license server:
set ARMLMD_LICENSE_FILE=8224@myserver
```

1. If the Arm Compiler 6 was installed as part of an Arm Development Studio, then you must set the `ARM_PRODUCT_DEF` to point to the product definition file: See also: Product and toolkit configuration. For example if the Arm Development Studio is installed in: `/opt/armds-2020-1` with a Gold license, then set `ARM_PRODUCT_DEF` to point to `/opt/armds-2020-1/gold.elmap`.

> **Note**
>
> The Arm Compiler 6 uses `armlink` for linking. This is incompatible with Zephyr's linker script template, which works with GNU ld. Zephyr's Arm Compiler 6 support Zephyr's CMake linker script generator, which supports generating scatter files. Basic scatter file support is in place, but there are still areas covered in ld templates which are not fully supported by the CMake linker script generator.
>
> Some Zephyr subsystems or modules may also contain C or assembly code that relies on GNU intrinsics and have not yet been updated to work fully with `armclang`.

2.14.3 Cadence Tensilica Xtensa C/C++ Compiler (XCC)

1. Obtain Tensilica Software Development Toolkit targeting the specific SoC on hand. This usually contains two parts:
   - The Xtensa Xplorer which contains the necessary executables and libraries.
   - A SoC-specific add-on to be installed on top of Xtensa Xplorer.

   - This add-on allows the compiler to generate code for the SoC on hand.

2. Install Xtensa Xplorer and then the SoC add-on.
   - Follow the instruction from Cadence on how to install the SDK.
   - Depending on the SDK, there are two set of compilers:
     - GCC-based compiler: `xt-xcc` and its friends.
     - Clang-based compiler: `xt-clang` and its friends.
3. Make sure you have obtained a license to use the SDK, or has access to a remote licensing server.
4. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `xcc` or `xt-clang`.
   - Set `XTENSA_TOOLCHAIN_PATH` to the toolchain installation directory.
   - Set `XTENSA_CORE` to the SoC ID where application is being targeting.
   - Set `TOOLCHAIN_VER` to the Xtensa SDK version.
5. For example, assuming the SDK is installed in `/opt/xtensa`, and using the SDK for application development on `intel_adsp_cavs15`, setup the environment using:

```
# Linux
export ZEPHYR_TOOLCHAIN_VARIANT=xcc
export XTENSA_TOOLCHAIN_PATH=/opt/xtensa/XtDevTools/install/tools/
export XTENSA_CORE=X6H3SUE_RI_2018_0
export TOOLCHAIN_VER=RI-2018.0-linux
```

6. To use Clang-based compiler:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `xt-clang`.
   - Note that the Clang-based compiler may contain an old LLVM bug which results in the following error:

```
/tmp/file.s: Assembler messages:
/tmp/file.s:20: Error: file number 1 already allocated
clang-3.9: error: Xtensa-as command failed with exit code 1
```

     If this happens, set `XCC_NO_G_FLAG` to `1`.
     - For example:

```
# Linux
export XCC_NO_G_FLAG=1
```

2.14.4 DesignWare ARC MetaWare Development Toolkit (MWDT)

1. You need to have ARC MWDT installed on your host.
2. You need to have *Zephyr SDK* installed on your host.

> **Note**
>
> A Zephyr SDK is used as a source of tools like device tree compiler (DTC), QEMU, etc... Even though ARC MWDT toolchain is used for Zephyr RTOS build, still the GNU preprocessor & GNU objcopy might be used for some steps like device tree preprocessing and `.bin` file generation. We used Zephyr SDK as a source of these ARC GNU tools as well. To setup ARC GNU toolchain please use SDK Bundle (Full or Minimal) instead of manual

installation of separate tarballs. It installs and registers toolchain and host tools in the system, that allows you to avoid toolchain related issues while building Zephyr.

3. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `arcmwdt`.
   - Set `ARCMWDT_TOOLCHAIN_PATH` to the toolchain installation directory. MWDT installation provides `METAWARE_ROOT` so simply set `ARCMWDT_TOOLCHAIN_PATH` to `$METAWARE_ROOT/../` (Linux) or `%METAWARE_ROOT%\..\` (Windows).

Tip

If you have only one ARC MWDT toolchain version installed on your machine you may skip setting `ARCMWDT_TOOLCHAIN_PATH` - it would be detected automatically.

4. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `ARCMWDT_TOOLCHAIN_PATH` values may be different on your system):

```
# Linux:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
arcmwdt
$ echo $ARCMWDT_TOOLCHAIN_PATH
/home/you/ARC/MWDT_2023.03/

# Windows:
> echo %ZEPHYR_TOOLCHAIN_VARIANT%
arcmwdt
> echo %ARCMWDT_TOOLCHAIN_PATH%
C:\ARC\MWDT_2023.03\
```

2.14.5 GNU Arm Embedded

1. Download and install a GNU Arm Embedded build for your operating system and extract it on your file system.

Note

On Windows, we'll assume for this guide that you install into the directory `C:\gnu_arm_embedded`. You can also choose the default installation path used by the ARM GCC installer, in which case you will need to adjust the path accordingly in the guide below.

Warning

On macOS Catalina or later you might need to *change a security policy* for the toolchain to be able to run from the terminal.

2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `gnuarmemb`.
   - Set `GNUARMEMB_TOOLCHAIN_PATH` to the toolchain installation directory.

3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the GNUARMEMB_TOOLCHAIN_PATH values may be different on your system):

```
# Linux, macOS:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
gnuarmemb
$ echo $GNUARMEMB_TOOLCHAIN_PATH
/home/you/Downloads/gnu_arm_embedded

# Windows:
> echo %ZEPHYR_TOOLCHAIN_VARIANT%
gnuarmemb
> echo %GNUARMEMB_TOOLCHAIN_PATH%
C:\gnu_arm_embedded
```

Warning

On macOS, if you are having trouble with the suggested procedure, there is an unofficial package on brew that might help you. Run `brew install gcc-arm-embedded` and configure the variables

- Set *ZEPHYR_TOOLCHAIN_VARIANT* to gnuarmemb.
- Set GNUARMEMB_TOOLCHAIN_PATH to the brew installation directory (something like /usr/local)

2.14.6 Intel oneAPI Toolkit

1. Download Intel oneAPI Base Toolkit
2. Assuming the toolkit is installed in /opt/intel/oneApi, set environment using:

```
# Linux, macOS:
export ONEAPI_TOOLCHAIN_PATH=/opt/intel/oneapi
source $ONEAPI_TOOLCHAIN_PATH/compiler/latest/env/vars.sh

# Windows:
> set ONEAPI_TOOLCHAIN_PATH=C:\Users\Intel\oneapi
```

   To setup the complete oneApi environment, use:

```
source  /opt/intel/oneapi/setvars.sh
```

   The above will also change the python environment to the one used by the toolchain and might conflict with what Zephyr uses.

3. Set *ZEPHYR_TOOLCHAIN_VARIANT* to oneApi.

2.14.7 Crosstool-NG (Deprecated)

Warning

xtools toolchain variant is deprecated. The *cross-compile toolchain variant* should be used when using a custom toolchain built with Crosstool-NG.

You can build toolchains from source code using crosstool-NG.

1. Follow the steps on the crosstool-NG website to prepare your host.
2. Follow the Zephyr SDK with Crosstool NG instructions to build your toolchain. Repeat as necessary to build toolchains for multiple target architectures.

   You will need to clone the `sdk-ng` repo and run the following command:

   ```
   ./go.sh <arch>
   ```

   Note

   Currently, only i586 and Arm toolchain builds are verified.

3. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `xtools`.
   - Set `XTOOLS_TOOLCHAIN_PATH` to the toolchain build directory.
4. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `XTOOLS_TOOLCHAIN_PATH` values may be different on your system):

   ```
   # Linux, macOS:
   $ echo $ZEPHYR_TOOLCHAIN_VARIANT
   xtools
   $ echo $XTOOLS_TOOLCHAIN_PATH
   /Volumes/CrossToolNGNew/build/output/
   ```

2.14.8 Host Toolchains

In some specific configurations, like when building for non-MCU x86 targets on a Linux host, you may be able to reuse the native development tools provided by your operating system.

To use your host gcc, set the *ZEPHYR_TOOLCHAIN_VARIANT environment variable* to `host`. To use clang, set *ZEPHYR_TOOLCHAIN_VARIANT* to `llvm`.

2.14.9 Other Cross Compilers

This toolchain variant is borrowed from the Linux kernel build system's mechanism of using a `CROSS_COMPILE` environment variable to set up a GNU-based cross toolchain.

Examples of such "other cross compilers" are cross toolchains that your Linux distribution packaged, that you compiled on your own, or that you downloaded from the net. Unlike toolchains specifically listed in *Toolchains*, the Zephyr build system may not have been tested with them, and doesn't officially support them. (Nonetheless, the toolchain set-up mechanism itself is supported.)

Follow these steps to use one of these toolchains.

1. Install a cross compiler suitable for your host and target systems.

   For example, you might install the `gcc-arm-none-eabi` package on Debian-based Linux systems, or `arm-none-eabi-newlib` on Fedora or Red Hat:

   ```
   # On Debian or Ubuntu
   sudo apt-get install gcc-arm-none-eabi
   # On Fedora or Red Hat
   sudo dnf install arm-none-eabi-newlib
   ```

2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `cross-compile`.
   - Set `CROSS_COMPILE` to the common path prefix which your toolchain's binaries have, e.g. the path to the directory containing the compiler binaries plus the target triplet and trailing dash.
3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `CROSS_COMPILE` value may be different on your system):

```
# Linux, macOS:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
cross-compile
$ echo $CROSS_COMPILE
/usr/bin/arm-none-eabi-
```

   You can also set `CROSS_COMPILE` as a CMake variable.

When using this option, all of your toolchain binaries must reside in the same directory and have a common file name prefix. The `CROSS_COMPILE` variable is set to the directory concatenated with the file name prefix. In the Debian example above, the `gcc-arm-none-eabi` package installs binaries such as `arm-none-eabi-gcc` and `arm-none-eabi-ld` in directory `/usr/bin/`, so the common prefix is `/usr/bin/arm-none-eabi-` (including the trailing dash, `-`). If your toolchain is installed in `/opt/mytoolchain/bin` with binary names based on target triplet `myarch-none-elf`, `CROSS_COMPILE` would be set to `/opt/mytoolchain/bin/myarch-none-elf-`.

2.14.10 Custom CMake Toolchains

To use a custom toolchain defined in an external CMake file, *set these environment variables*:

- Set *ZEPHYR_TOOLCHAIN_VARIANT* to your toolchain's name
- Set `TOOLCHAIN_ROOT` to the path to the directory containing your toolchain's CMake configuration files.

Zephyr will then include the toolchain cmake files located in the `TOOLCHAIN_ROOT` directory:

- `cmake/toolchain/<toolchain name>/generic.cmake`: configures the toolchain for "generic" use, which mostly means running the C preprocessor on the generated *Devicetree* file.
- `cmake/toolchain/<toolchain name>/target.cmake`: configures the toolchain for "target" use, i.e. building Zephyr and your application's source code.

Here <toolchain name> is the same as the name provided in *ZEPHYR_TOOLCHAIN_VARIANT* See the zephyr files cmake/modules/FindHostTools.cmake and cmake/modules/FindTargetTools.cmake for more details on what your `generic.cmake` and `target.cmake` files should contain.

You can also set `ZEPHYR_TOOLCHAIN_VARIANT` and `TOOLCHAIN_ROOT` as CMake variables when generating a build system for a Zephyr application, like so:

```
west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

```
cmake -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

If you do this, `-C <initial-cache>` cmake option may useful. If you save your **ZEPHYR_TOOLCHAIN_VARIANT**, **TOOLCHAIN_ROOT**, and other settings in a file named `my-toolchain.cmake`, you can then invoke cmake as `cmake -C my-toolchain.cmake ...` to save typing.

Zephyr includes `include/toolchain.h` which again includes a toolchain specific header based on the compiler identifier, such as `__llvm__` or `__GNUC__`. Some custom compilers identify themselves as the compiler on which they are based, for example `llvm` which then gets the `toolchain/llvm.h` included. This included file may though not be right for the custom

toolchain. In order to solve this, and thus to get the `include/other.h` included instead, add the set(TOOLCHAIN_USE_CUSTOM 1) cmake line to the generic.cmake and/or target.cmake files located under `<TOOLCHAIN_ROOT>/cmake/toolchain/<toolchain name>/`.

When **TOOLCHAIN_USE_CUSTOM** is set, the `other.h` must be available out-of-tree and it must include the correct header for the custom toolchain. A good location for the `other.h` header file, would be a directory under the directory specified in `TOOLCHAIN_ROOT` as `include/toolchain`. To get the toolchain header included in zephyr's build, the **USERINCLUDE** can be set to point to the include directory, as shown here:

```
west build -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=... -DUSERINCLUDE=...
```

2.15 Tools and IDEs

2.15.1 CLion

CLion is a cross-platform C/C++ IDE that supports multi-threaded RTOS debugging.

This guide describes the process of setting up, building, and debugging Zephyr's multi-thread-blinky sample in CLion.

The instructions have been tested on Windows. In terms of the CLion workflow, the steps would be the same for macOS and Linux, but make sure to select the correct environment file and to adjust the paths.

Get CLion

Download CLion and install it.

Initialize a new workspace

This guide gives details on how to build and debug the multi-thread-blinky sample application, but the instructions would be similar for any Zephyr project and *workspace layout*.

Before you start, make sure you have a working Zephyr development environment, as per the instructions in the *Getting Started Guide*.

Open the project in CLion

1. In CLion, click *Open* on the Welcome screen or select *File* ▸ *Open* from the main menu.
2. Navigate to your Zephyr workspace (i.e.the `zephyrproject` folder in your HOME directory if you have followed the Getting Started instructions), then select `zephyr/samples/basic/threads` or another sample project folder.

   Click *OK*.
3. If prompted, click *Trust Project*.

   See the Project security section in CLion web help for more information on project security.

Configure the toolchain and CMake profile

CLion will open the *Open Project Wizard* with the CMake profile settings. If that does not happen, go to *Settings* ▸ *Build, Execution, Deployment* ▸ *CMake*.

1. Click *Manage Toolchains* next to the *Toolchain* field. This will open the *Toolchain* settings dialog.
2. We recommend that you use the *Bundled MinGW* toolchain with default settings on Windows, or the *System* (default) toolchain on Unix machines.
3. Click *Add environment* ▸ *From file* and select `..\.venv\Scripts\activate.bat`.

   Click *Apply* to save the changes.

4. Back in the CMake profile settings dialog, specify your board in the *CMake options* field. For example:

   ```
   -DBOARD=nrf52840dk/nrf52840
   ```

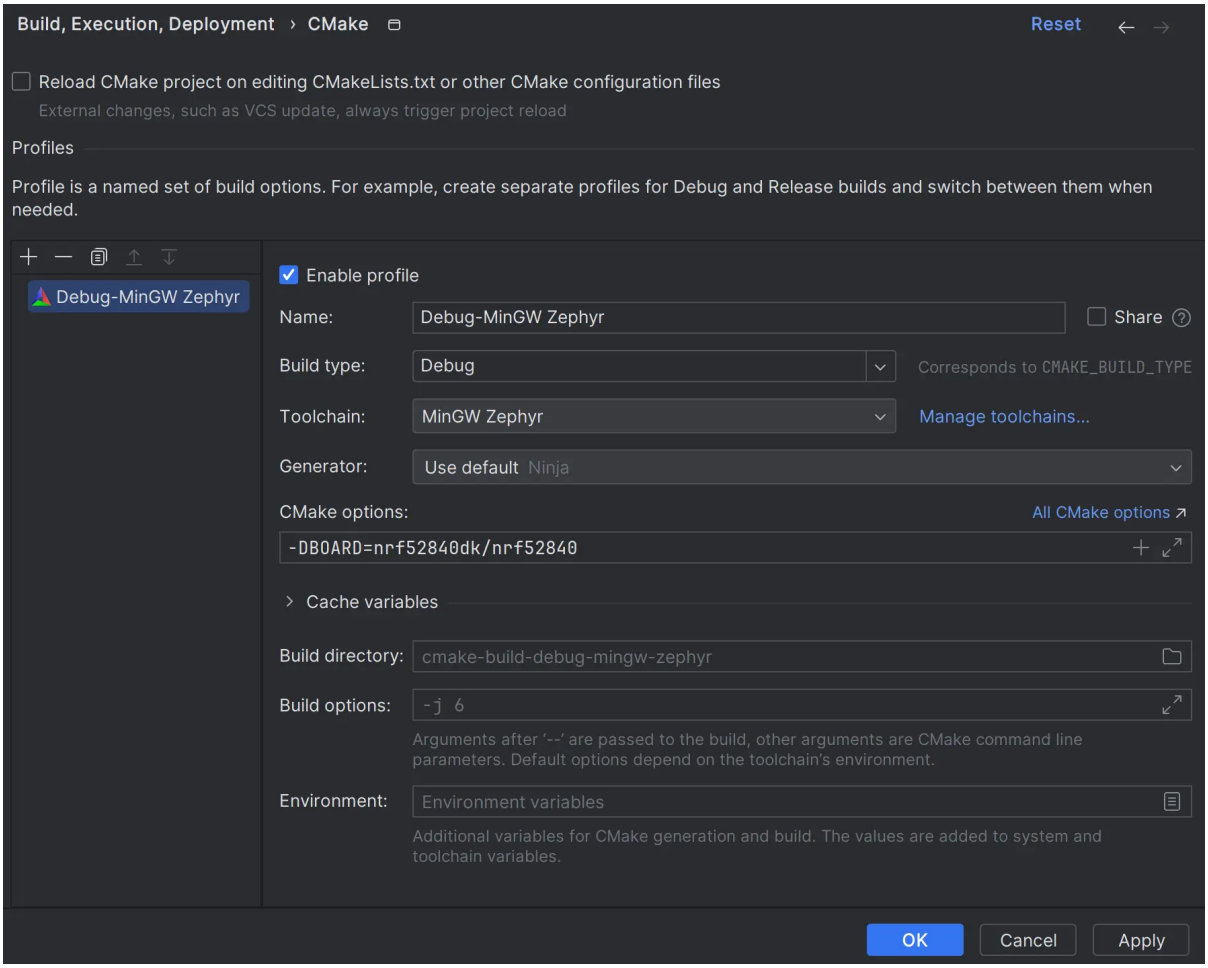
5. Click *Apply* to save the changes.

   CMake load should finish successfully.

Configure Zephyr parameters for debug

1. In the configuration switcher on the top right, select *guiconfig* and click the hammer icon.
2. Use the GUI application to set the following flags:

   ```
   DEBUG_THREAD_INFO
   THREAD_RUNTIME_STATS
   DEBUG_OPTIMIZATIONS
   ```



Build, Execution, Deployment › CMake
Reset
Reload CMake project on editing CMakeLists.txt or other CMake configuration files
External changes, such as VCS update, always trigger project reload
Profiles
Profile is a named set of build options. For example, create separate profiles for Debug and Release builds and switch between them when needed.
Debug-MinGW Zephyr
Enable profile

Debug-MinGW Zephyr
Share
Build type:
Debug
Corresponds to CMAKE_BUILD_TYPE
Toolchain:
MinGW Zephyr
Manage toolchains...
Generator:
Use default Ninja
CMake options:
All CMake options
-DBOARD=nrf52840dk/nrf52840
Cache variables
Build directory:
cmake-build-debug-mingw-zephyr
Build options:
-j 6
Arguments after '--' are passed to the build, other arguments are CMake command line parameters. Default options depend on the toolchain's environment.
Environment:
Environment variables
Additional variables for CMake generation and build. The values are added to system and toolchain variables.
OK
Cancel
Apply

Build the project

In the configuration switcher, select **zephyr_final** and click the hammer icon.

Note that other CMake targets like `puncover` or `hardenconfig` can also be called at this point.

Enable RTOS integration

1. Go to *Settings* ▸ *Build, Execution, Deployment* ▸ *Embedded Development* ▸ *RTOS Integration*.
2. Set the *Enable RTOS Integration* checkbox.

   This option enables Zephyr tasks view during debugging. See Multi-threaded RTOS debug in CLion web help for more information.

   You can leave the option set to *Auto*. CLion will detect Zephyr automatically.

Create an Embedded GDB Server configuration

In order to debug a Zephyr application in CLion, you need to create a run/debug configuration out of the Embedded GDB Server template.

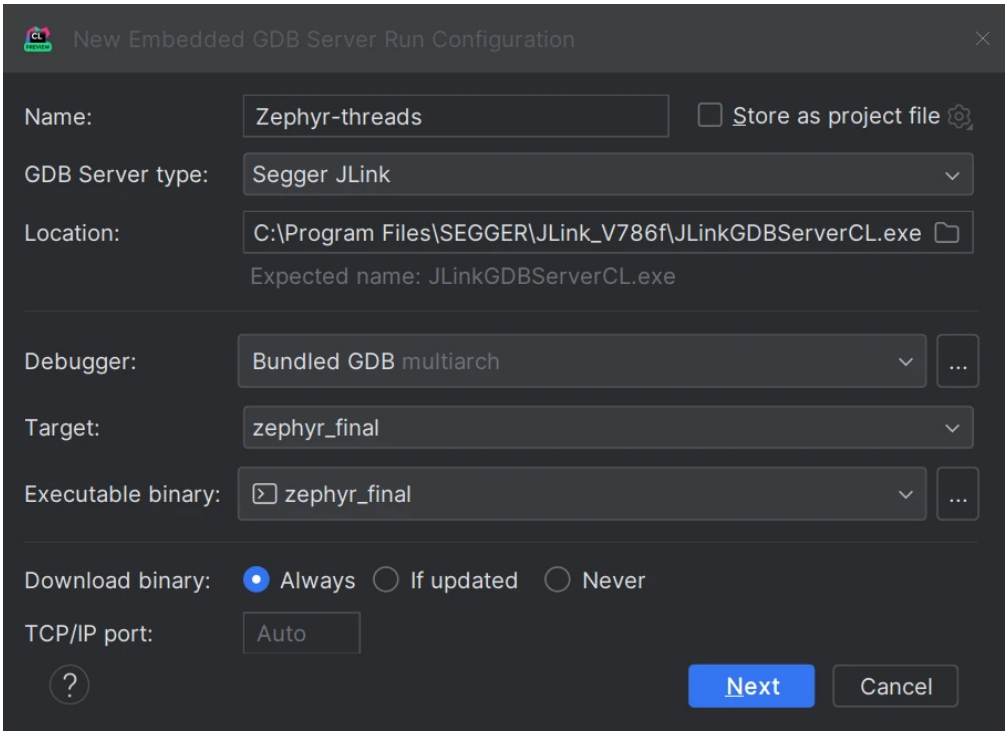
Instructions below show the case of a Nordic Semiconductor board and a Segger J-Link debug probe. If your setup is different, make sure to adjust the configuration settings accordingly.

1. Select *Run* ▸ *New Embedded Configuration* from the main menu.
2. Configure the settings:

Option	Value
Name (optional)	Zephyr-threads
GDB Server Type	Segger JLink
Location	The path to `JLinkGDBServerCL.exe` on Windows or the `JLinkGDBServer` binary on macOS/Linux.
Debugger	Bundled GDB **Note** For non-ARM and non-x86 architectures, use a GDB executable from Zephyr SDK. Make sure to pick a version with Python support (for example, **riscv64-zephyr-elf-gdb-py**) and check that Python is present in the system `PATH`.
Target	zephyr-final
Executable binary	zephyr-final
Download binary	Always
TCP/IP port	Auto

3. Click *Next* to set the Segger J-Link parameters.

4. Click *Create* when ready.



New Embedded GDB Server Run Configuration

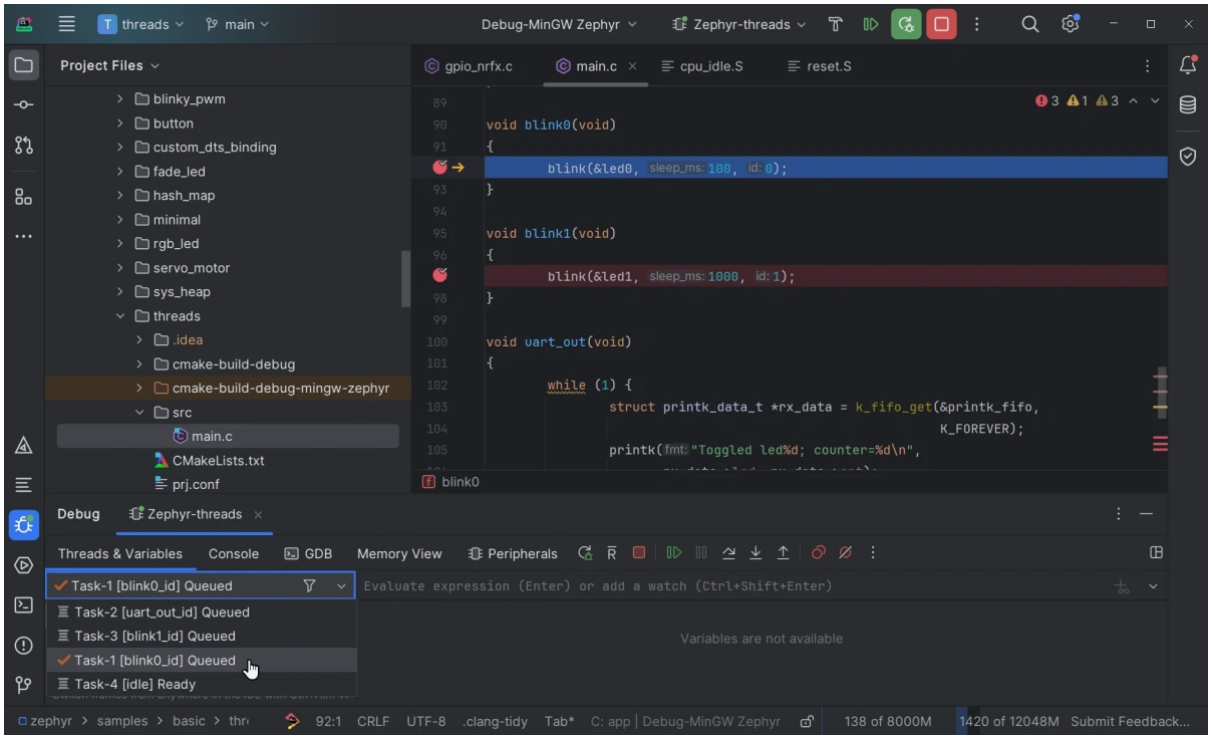
Create
Cancel

Start debugging

1. Place breakpoints by clicking in the left gutter next to the code lines.
2. Make sure that **Zephyr-threads** is selected in the configuration switcher and click the bug icon or press `Ctrl+D`.
3. When a breakpoint is hit, CLion opens the Debug tool window.

   Zephyr tasks are listed in the *Threads & Variables* pane. You can switch between them and inspect the variables for each task.



Refer to CLion web help for detailed description of the IDE debug capabilities.

2.15.2 Coccinelle

Coccinelle is a tool for pattern matching and text transformation that has many uses in kernel development, including the application of complex, tree-wide patches and detection of problematic programming patterns.

> **Note**
>
> Linux and macOS development environments are supported, but not Windows.

Getting Coccinelle

The semantic patches included in the kernel use features and options which are provided by Coccinelle version 1.0.0-rc11 and above. Using earlier versions will fail as the option names used by the Coccinelle files and `coccicheck` have been updated.

Coccinelle is available through the package manager of many distributions, e.g. :

- Debian
- Fedora
- Ubuntu
- OpenSUSE
- Arch Linux
- NetBSD
- FreeBSD

Some distribution packages are obsolete and it is recommended to use the latest version released from the Coccinelle homepage at http://coccinelle.lip6.fr/

Or from Github at:

https://github.com/coccinelle/coccinelle

Once you have it, run the following commands:

```
./autogen
./configure
make
```

as a regular user, and install it with:

```
sudo make install
```

More detailed installation instructions to build from source can be found at:

https://github.com/coccinelle/coccinelle/blob/master/install.txt

Supplemental documentation

For Semantic Patch Language(SmPL) grammar documentation refer to:

https://coccinelle.gitlabpages.inria.fr/website/documentation.html

Using Coccinelle on Zephyr

`coccicheck` checker is the front-end to the Coccinelle infrastructure and has various modes:

Four basic modes are defined: `patch`, `report`, `context`, and `org`. The mode to use is specified by setting `--mode=<mode>` or `-m=<mode>`.

- `patch` proposes a fix, when possible.
- `report` generates a list in the following format: file:line:column-column: message
- `context` highlights lines of interest and their context in a diff-like style.Lines of interest are indicated with `-`.
- `org` generates a report in the Org mode format of Emacs.

Note that not all semantic patches implement all modes. For easy use of Coccinelle, the default mode is `report`.

Two other modes provide some common combinations of these modes.

- `chain` tries the previous modes in the order above until one succeeds.
- `rep+ctxt` runs successively the report mode and the context mode. It should be used with the C option (described later) which checks the code on a file basis.

Examples

To make a report for every semantic patch, run the following command:

```
./scripts/coccicheck --mode=report
```

To produce patches, run:

```
./scripts/coccicheck --mode=patch
```

The `coccicheck` target applies every semantic patch available in the sub-directories of `scripts/coccinelle` to the entire source code tree.

For each semantic patch, a commit message is proposed. It gives a description of the problem being checked by the semantic patch, and includes a reference to Coccinelle.

As any static code analyzer, Coccinelle produces false positives. Thus, reports must be carefully checked, and patches reviewed.

To enable verbose messages set `--verbose=1` option, for example:

```
./scripts/coccicheck --mode=report --verbose=1
```

Coccinelle parallelization

By default, `coccicheck` tries to run as parallel as possible. To change the parallelism, set the `--jobs=<number>` option. For example, to run across 4 CPUs:

```
./scripts/coccicheck --mode=report --jobs=4
```

As of Coccinelle 1.0.2 Coccinelle uses Ocaml parmap for parallelization, if support for this is detected you will benefit from parmap parallelization.

When parmap is enabled `coccicheck` will enable dynamic load balancing by using `--chunksize 1` argument, this ensures we keep feeding threads with work one by one, so that we avoid the situation where most work gets done by only a few threads. With dynamic load balancing, if a thread finishes early we keep feeding it more work.

When parmap is enabled, if an error occurs in Coccinelle, this error value is propagated back, the return value of the `coccicheck` command captures this return value.

Using Coccinelle with a single semantic patch

The option `--cocci` can be used to check a single semantic patch. In that case, the variable must be initialized with the name of the semantic patch to apply.

For instance:

```
./scripts/coccicheck --mode=report --cocci=<example.cocci>
```

or:

```
./scripts/coccicheck --mode=report --cocci=./path/to/<example.cocci>
```

Controlling which files are processed by Coccinelle

By default the entire source tree is checked.

To apply Coccinelle to a specific directory, pass the path of specific directory as an argument.

For example, to check drivers/usb/ one may write:

```
./scripts/coccicheck --mode=patch drivers/usb/
```

The report mode is the default. You can select another one with the --mode=<mode> option explained above.

Debugging Coccinelle SmPL patches

Using coccicheck is best as it provides in the spatch command line include options matching the options used when we compile the kernel. You can learn what these options are by using verbose option, you could then manually run Coccinelle with debug options added.

Alternatively you can debug running Coccinelle against SmPL patches by asking for stderr to be redirected to stderr, by default stderr is redirected to /dev/null, if you'd like to capture stderr you can specify the --debug=file.err option to coccicheck. For instance:

```
rm -f cocci.err
./scripts/coccicheck --mode=patch --debug=cocci.err
cat cocci.err
```

Debugging support is only supported when using Coccinelle >= 1.0.2.

Additional Flags

Additional flags can be passed to spatch through the SPFLAGS variable. This works as Coccinelle respects the last flags given to it when options are in conflict.

```
./scripts/coccicheck --sp-flag="--use-glimpse"
```

Coccinelle supports idutils as well but requires coccinelle >= 1.0.6. When no ID file is specified coccinelle assumes your ID database file is in the file .id-utils.index on the top level of the kernel, coccinelle carries a script scripts/idutils_index.sh which creates the database with:

```
mkid -i C --output .id-utils.index
```

If you have another database filename you can also just symlink with this name.

```
./scripts/coccicheck --sp-flag="--use-idutils"
```

Alternatively you can specify the database filename explicitly, for instance:

```
./scripts/coccicheck --sp-flag="--use-idutils /full-path/to/ID"
```

Sometimes coccinelle doesn't recognize or parse complex macro variables due to insufficient definition. Therefore, to make it parsable we explicitly provide the prototype of the complex macro using the ---macro-file-builtins <headerfile.h> flag.

The <headerfile.h> should contain the complete prototype of the complex macro from which spatch engine can extract the type information required during transformation.

For example:

Z_SYSCALL_HANDLER is not recognized by coccinelle. Therefore, we put its prototype in a header file, say for example mymacros.h.

```
$ cat mymacros.h
#define Z_SYSCALL_HANDLER int xxx
```

Now we pass the header file mymacros.h during transformation:

```
./scripts/coccicheck --sp-flag="---macro-file-builtins mymacros.h"
```

See `spatch --help` to learn more about spatch options.

Note that the `--use-glimpse` and `--use-idutils` options require external tools for indexing the code. None of them is thus active by default. However, by indexing the code with one of these tools, and according to the cocci file used, spatch could proceed the entire code base more quickly.

SmPL patch specific options

SmPL patches can have their own requirements for options passed to Coccinelle. SmPL patch specific options can be provided by providing them at the top of the SmPL patch, for instance:

```
// Options: --no-includes --include-headers
```

Proposing new semantic patches

New semantic patches can be proposed and submitted by kernel developers. For sake of clarity, they should be organized in the sub-directories of `scripts/coccinelle/`.

The cocci script should have the following properties:

- The script **must** have `report` mode.
- The first few lines should state the purpose of the script using `///` comments . Usually, this message would be used as the commit log when proposing a patch based on the script.

Example

```
/// Use ARRAY_SIZE instead of dividing sizeof array with sizeof an element
```

- A more detailed information about the script with exceptional cases or false positives (if any) can be listed using `//#` comments.

Example

```
//# This makes an effort to find cases where ARRAY_SIZE can be used such as
//# where there is a division of sizeof the array by the sizeof its first
//# element or by any indexed element or the element type. It replaces the
//# division of the two sizeofs by ARRAY_SIZE.
```

- Confidence: It is a property defined to specify the accuracy level of the script. It can be either `High`, `Moderate` or `Low` depending upon the number of false positives observed.

Example

```
// Confidence: High
```

- Virtual rules: These are required to support the various modes framed in the script. The virtual rule specified in the script should have the corresponding mode handling rule.

Example

```
virtual context

Detailed description of the `org` mode

`org` generates a report in the Org mode format of Emacs.

Example Running:

```
./scripts/coccicheck --mode=org --cocci=scripts/coccinelle/misc/array_size.cocci
```

will execute the following part of the SmPL script:

```
<smpl>

@r depends on (org || report)@
type T;
T[] E;
position p;
@@
(
(sizeof(E)@p /sizeof(*E))
|
(sizeof(E)@p /sizeof(E[...]))
|
(sizeof(E)@p /sizeof(T))
)
```

(continues on next page)

(continued from previous page)

```
@script:python depends on org@
p << r.p;
@@
coccilib.org.print_todo(p[0], "WARNING should use ARRAY_SIZE")

</smpl>
```

This SmPL excerpt generates Org entries on the standard output, as illustrated below:

```

2.15.3 Visual Studio Code

Visual Studio Code (VS Code for short) is a popular cross-platform IDE that supports C projects and has a rich set of extensions.

This guide describes the process of setting up VS Code for Zephyr's blinky sample in VS Code.

The instructions have been tested on Linux, but the steps should be the same for macOS and Windows, just make sure to adjust the paths if needed.

Get VS Code

Download VS Code and install it.

Install the required extensions through the *Extensions* marketplace in the left panel. Search for the C/C++ Extension Pack and install it.

Initialize a new workspace

This guide gives details on how to configure the blinky sample application, but the instructions would be similar for any Zephyr project and *workspace layout*.

Before you start, make sure you have a working Zephyr development environment, as per the instructions in the *Getting Started Guide*.

Open the project in VS Code

1. In VS Code, select *File* ▸ *Open Folder* from the main menu.
2. Navigate to your Zephyr workspace and select it (i.e. the `zephyrproject` folder in your HOME directory if you have followed the Getting Started instructions).

3. If prompted, enable workspace trust.

Generate compile commands

In order to support code navigation and linting capabilities, you must compile your project once to generate the `compile_commands.json` file that will provide the C/C++ extension with the required information (ex. include paths):

```
west build -b native_sim/native/64 samples/basic/blinky
```

Configure the C/C++ extension

You'll now need to point to the generated `compile_commands.json` file to enable linting and code navigation in VS Code.

1. Go to the *File* ▸ *Preferences* ▸ *Settings* in the VS Code top menu.
2. Search for the parameter *C_Cpp* > *Default: Compile Commands* and set its value to: `zephyr/build/compile_commands.json`.

   Linting errors in the code should now be resolved, and you should be able to navigate through the code.

Additional resources

There are many other extensions that can be useful when working with Zephyr and VS Code. While this guide does not cover them yet, you may refer to their documentation to set them up:

Contribution tooling

- Checkpatch Extension
- EditorConfig Extension

Documentation languages extensions

- reStructuredText Extension Pack

IDE extensions

- CMake Extension documentation
- nRF Kconfig Extension
- nRF DeviceTree Extension
- GNU Linker Map files Extension

Additional guides

- How to Develop Zephyr Apps with a Modern, Visual IDE

> **Note**
>
> Please be aware that these extensions might not all have the same level of quality and maintenance.

Chapter 3

Kernel

3.1 Kernel Services

The Zephyr kernel lies at the heart of every Zephyr application. It provides a low footprint, high performance, multi-threaded execution environment with a rich set of available features. The rest of the Zephyr ecosystem, including device drivers, networking stack, and application-specific code, uses the kernel's features to create a complete application.

The configurable nature of the kernel allows you to incorporate only those features needed by your application, making it ideal for systems with limited amounts of memory (as little as 2 KB!) or with simple multi-threading requirements (such as a set of interrupt handlers and a single background task). Examples of such systems include: embedded sensor hubs, environmental sensors, simple LED wearable, and store inventory tags.

Applications requiring more memory (50 to 900 KB), multiple communication devices (like Wi-Fi and Bluetooth Low Energy), and complex multi-threading, can also be developed using the Zephyr kernel. Examples of such systems include: fitness wearables, smart watches, and IoT wireless gateways.

3.1.1 Scheduling, Interrupts, and Synchronization

These pages cover basic kernel services related to thread scheduling and synchronization.

Threads

Note

There is also limited support for using *Operation without Threads*.

- *API Reference*

This section describes kernel services for creating, scheduling, and deleting independently executable threads of instructions.

A *thread* is a kernel object that is used for application processing that is too lengthy or too complex to be performed by an ISR.

Any number of threads can be defined by an application (limited only by available RAM). Each thread is referenced by a *thread id* that is assigned when the thread is spawned.

A thread has the following key properties:

- A **stack area**, which is a region of memory used for the thread's stack. The **size** of the stack area can be tailored to conform to the actual needs of the thread's processing. Special macros exist to create and work with stack memory regions.
- A **thread control block** for private kernel bookkeeping of the thread's metadata. This is an instance of type `k_thread`.
- An **entry point function**, which is invoked when the thread is started. Up to 3 **argument values** can be passed to this function.
- A **scheduling priority**, which instructs the kernel's scheduler how to allocate CPU time to the thread. (See *Scheduling*.)
- A set of **thread options**, which allow the thread to receive special treatment by the kernel under specific circumstances. (See *Thread Options*.)
- A **start delay**, which specifies how long the kernel should wait before starting the thread.
- An **execution mode**, which can either be supervisor or user mode. By default, threads run in supervisor mode and allow access to privileged CPU instructions, the entire memory address space, and peripherals. User mode threads have a reduced set of privileges. This depends on the `CONFIG_USERSPACE` option. See *User Mode*.

Lifecycle

Thread Creation A thread must be created before it can be used. The kernel initializes the thread control block as well as one end of the stack portion. The remainder of the thread's stack is typically left uninitialized.

Specifying a start delay of *K_NO_WAIT* instructs the kernel to start thread execution immediately. Alternatively, the kernel can be instructed to delay execution of the thread by specifying a timeout value – for example, to allow device hardware used by the thread to become available.

The kernel allows a delayed start to be canceled before the thread begins executing. A cancellation request has no effect if the thread has already started. A thread whose delayed start was successfully canceled must be re-spawned before it can be used.

Thread Termination Once a thread is started it typically executes forever. However, a thread may synchronously end its execution by returning from its entry point function. This is known as **termination**.

A thread that terminates is responsible for releasing any shared resources it may own (such as mutexes and dynamically allocated memory) prior to returning, since the kernel does *not* reclaim them automatically.

In some cases a thread may want to sleep until another thread terminates. This can be accomplished with the *k_thread_join()* API. This will block the calling thread until either the timeout expires, the target thread self-exits, or the target thread aborts (either due to a *k_thread_abort()* call or triggering a fatal error).

Once a thread has terminated, the kernel guarantees that no use will be made of the thread struct. The memory of such a struct can then be re-used for any purpose, including spawning a new thread. Note that the thread must be fully terminated, which presents race conditions where a thread's own logic signals completion which is seen by another thread before the kernel processing is complete. Under normal circumstances, application code should use *k_thread_join()* or *k_thread_abort()* to synchronize on thread termination state and not rely on signaling from within application logic.

Thread Aborting A thread may asynchronously end its execution by **aborting**. The kernel automatically aborts a thread if the thread triggers a fatal error condition, such as dereferencing a null pointer.

A thread can also be aborted by another thread (or by itself) by calling *k_thread_abort()*. However, it is typically preferable to signal a thread to terminate itself gracefully, rather than aborting it.

As with thread termination, the kernel does not reclaim shared resources owned by an aborted thread.

Note

The kernel does not currently make any claims regarding an application's ability to respawn a thread that aborts.

Thread Suspension A thread can be prevented from executing for an indefinite period of time if it becomes **suspended**. The function *k_thread_suspend()* can be used to suspend any thread, including the calling thread. Suspending a thread that is already suspended has no additional effect.

Once suspended, a thread cannot be scheduled until another thread calls *k_thread_resume()* to remove the suspension.

Note

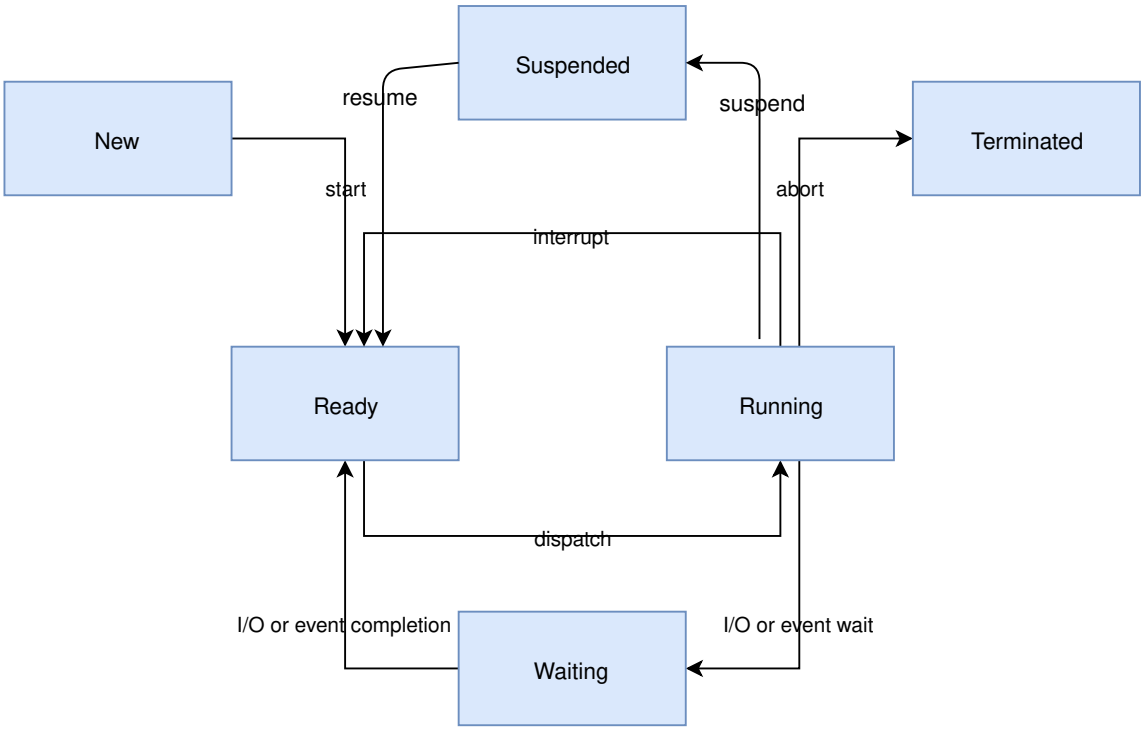
A thread can prevent itself from executing for a specified period of time using *k_sleep()*. However, this is different from suspending a thread since a sleeping thread becomes executable automatically when the time limit is reached.

Thread States A thread that has no factors that prevent its execution is deemed to be **ready**, and is eligible to be selected as the current thread.

A thread that has one or more factors that prevent its execution is deemed to be **unready**, and cannot be selected as the current thread.

The following factors make a thread unready:

- The thread has not been started.
- The thread is waiting for a kernel object to complete an operation. (For example, the thread is taking a semaphore that is unavailable.)
- The thread is waiting for a timeout to occur.
- The thread has been suspended.
- The thread has terminated or aborted.



Note

Although the diagram above may appear to suggest that both **Ready** and **Running** are distinct thread states, that is not the correct interpretation. **Ready** is a thread state, and **Running** is a schedule state that only applies to **Ready** threads.

Thread Stack objects Every thread requires its own stack buffer for the CPU to push context. Depending on configuration, there are several constraints that must be met:

- There may need to be additional memory reserved for memory management structures

- If guard-based stack overflow detection is enabled, a small write- protected memory management region must immediately precede the stack buffer to catch overflows.
- If userspace is enabled, a separate fixed-size privilege elevation stack must be reserved to serve as a private kernel stack for handling system calls.
- If userspace is enabled, the thread's stack buffer must be appropriately sized and aligned such that a memory protection region may be programmed to exactly fit.

The alignment constraints can be quite restrictive, for example some MPUs require their regions to be of some power of two in size, and aligned to its own size.

Because of this, portable code can't simply pass an arbitrary character buffer to *k_thread_create()*. Special macros exist to instantiate stacks, prefixed with K_KERNEL_STACK and K_THREAD_STACK.

Kernel-only Stacks If it is known that a thread will never run in user mode, or the stack is being used for special contexts like handling interrupts, it is best to define stacks using the K_KERNEL_STACK macros.

These stacks save memory because an MPU region will never need to be programmed to cover the stack buffer itself, and the kernel will not need to reserve additional room for the privilege elevation stack, or memory management data structures which only pertain to user mode threads.

Attempts from user mode to use stacks declared in this way will result in a fatal error for the caller.

If CONFIG_USERSPACE is not enabled, the set of K_THREAD_STACK macros have an identical effect to the K_KERNEL_STACK macros.

Thread stacks If it is known that a stack will need to host user threads, or if this cannot be determined, define the stack with K_THREAD_STACK macros. This may use more memory but the stack object is suitable for hosting user threads.

If CONFIG_USERSPACE is not enabled, the set of K_THREAD_STACK macros have an identical effect to the K_KERNEL_STACK macros.

Thread Priorities A thread's priority is an integer value, and can be either negative or non-negative. Numerically lower priorities takes precedence over numerically higher values. For example, the scheduler gives thread A of priority 4 *higher* priority over thread B of priority 7; likewise thread C of priority -2 has higher priority than both thread A and thread B.

The scheduler distinguishes between two classes of threads, based on each thread's priority.

- A *cooperative thread* has a negative priority value. Once it becomes the current thread, a cooperative thread remains the current thread until it performs an action that makes it unready.
- A *preemptible thread* has a non-negative priority value. Once it becomes the current thread, a preemptible thread may be supplanted at any time if a cooperative thread, or a preemptible thread of higher or equal priority, becomes ready.

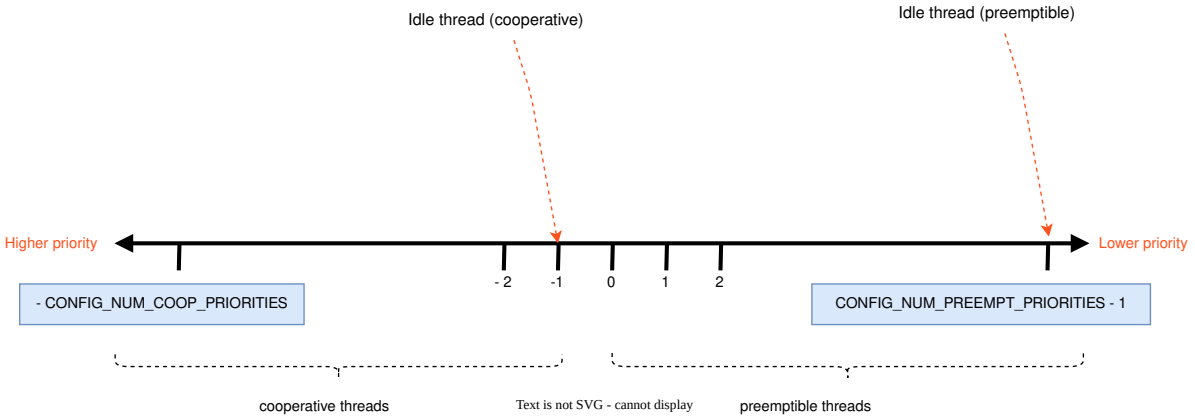
A thread's initial priority value can be altered up or down after the thread has been started. Thus it is possible for a preemptible thread to become a cooperative thread, and vice versa, by changing its priority.

Note

The scheduler does not make heuristic decisions to re-prioritize threads. Thread priorities are set and changed only at the application's request.

The kernel supports a virtually unlimited number of thread priority levels. The configuration options CONFIG_NUM_COOP_PRIORITIES and CONFIG_NUM_PREEMPT_PRIORITIES specify the number of priority levels for each class of thread, resulting in the following usable priority ranges:

- cooperative threads: (-CONFIG_NUM_COOP_PRIORITIES) to -1
- preemptive threads: 0 to (CONFIG_NUM_PREEMPT_PRIORITIES - 1)



For example, configuring 5 cooperative priorities and 10 preemptive priorities results in the ranges -5 to -1 and 0 to 9, respectively.

Meta-IRQ Priorities When enabled (see CONFIG_NUM_METAIRQ_PRIORITIES), there is a special subclass of cooperative priorities at the highest (numerically lowest) end of the priority space: meta-IRQ threads. These are scheduled according to their normal priority, but also have the special ability to preempt all other threads (and other meta-IRQ threads) at lower priorities, even if those threads are cooperative and/or have taken a scheduler lock. Meta-IRQ threads are still threads, however, and can still be interrupted by any hardware interrupt.

This behavior makes the act of unblocking a meta-IRQ thread (by any means, e.g. creating it, calling k_sem_give(), etc.) into the equivalent of a synchronous system call when done by a lower priority thread, or an ARM-like "pended IRQ" when done from true interrupt context. The intent is that this feature will be used to implement interrupt "bottom half" processing and/or "tasklet" features in driver subsystems. The thread, once woken, will be guaranteed to run before the current CPU returns into application code.

Unlike similar features in other OSes, meta-IRQ threads are true threads and run on their own stack (which must be allocated normally), not the per-CPU interrupt stack. Design work to enable the use of the IRQ stack on supported architectures is pending.

Note that because this breaks the promise made to cooperative threads by the Zephyr API (namely that the OS won't schedule other thread until the current thread deliberately blocks), it should be used only with great care from application code. These are not simply very high priority threads and should not be used as such.

Thread Options The kernel supports a small set of *thread options* that allow a thread to receive special treatment under specific circumstances. The set of options associated with a thread are specified when the thread is spawned.

A thread that does not require any thread option has an option value of zero. A thread that requires a thread option specifies it by name, using the | character as a separator if multiple options are needed (i.e. combine options using the bitwise OR operator).

The following thread options are supported.

K_ESSENTIAL
: This option tags the thread as an *essential thread*. This instructs the kernel to treat the termination or aborting of the thread as a fatal system error.

By default, the thread is not considered to be an essential thread.

K_SSE_REGS
: This x86-specific option indicate that the thread uses the CPU's SSE registers. Also see *K_FP_REGS*.

  By default, the kernel does not attempt to save and restore the contents of these registers when scheduling the thread.

K_FP_REGS
: This option indicate that the thread uses the CPU's floating point registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. (For more information see *Floating Point Services*.)

  By default, the kernel does not attempt to save and restore the contents of this register when scheduling the thread.

K_USER
: If CONFIG_USERSPACE is enabled, this thread will be created in user mode and will have reduced privileges. See *User Mode*. Otherwise this flag does nothing.

K_INHERIT_PERMS
: If CONFIG_USERSPACE is enabled, this thread will inherit all kernel object permissions that the parent thread had, except the parent thread object. See *User Mode*.

Thread Custom Data Every thread has a 32-bit *custom data* area, accessible only by the thread itself, and may be used by the application for any purpose it chooses. The default custom data value for a thread is zero.

> **Note**
>
> Custom data support is not available to ISRs because they operate within a single shared kernel interrupt handling context.

By default, thread custom data support is disabled. The configuration option CONFIG_THREAD_CUSTOM_DATA can be used to enable support.

The *k_thread_custom_data_set()* and *k_thread_custom_data_get()* functions are used to write and read a thread's custom data, respectively. A thread can only access its own custom data, and not that of another thread.

The following code uses the custom data feature to record the number of times each thread calls a specific routine.

> **Note**
>
> Obviously, only a single routine can use this technique, since it monopolizes the use of the custom data feature.

```
int call_tracking_routine(void)
{
    uint32_t call_count;

    if (k_is_in_isr()) {
        /* ignore any call made by an ISR */
    } else {
        call_count = (uint32_t)k_thread_custom_data_get();
        call_count++;
        k_thread_custom_data_set((void *)call_count);
```

(continues on next page)

(continued from previous page)

```
    }

    /* do rest of routine's processing */
    ...
}
```

Use thread custom data to allow a routine to access thread-specific information, by using the custom data as a pointer to a data structure owned by the thread.

Implementation

Spawning a Thread A thread is spawned by defining its stack area and its thread control block, and then calling *k_thread_create()*.

The stack area must be defined using *K_THREAD_STACK_DEFINE* or *K_KERNEL_STACK_DEFINE* to ensure it is properly set up in memory.

The size parameter for the stack must be one of three values:

- The original requested stack size passed to K_THREAD_STACK or K_KERNEL_STACK family of stack instantiation macros.
- For a stack object defined with the K_THREAD_STACK family of macros, the return value of *K_THREAD_STACK_SIZEOF()* for that' object.
- For a stack object defined with the K_KERNEL_STACK family of macros, the return value of *K_KERNEL_STACK_SIZEOF()* for that object.

The thread spawning function returns its thread id, which can be used to reference the thread.

The following code spawns a thread that starts immediately.

```
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5

extern void my_entry_point(void *, void *, void *);

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);
struct k_thread my_thread_data;

k_tid_t my_tid = k_thread_create(&my_thread_data, my_stack_area,
                                 K_THREAD_STACK_SIZEOF(my_stack_area),
                                 my_entry_point,
                                 NULL, NULL, NULL,
                                 MY_PRIORITY, 0, K_NO_WAIT);
```

Alternatively, a thread can be declared at compile time by calling *K_THREAD_DEFINE*. Observe that the macro defines the stack area, control block, and thread id variables automatically.

The following code has the same effect as the code segment above.

```
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5

extern void my_entry_point(void *, void *, void *);

K_THREAD_DEFINE(my_tid, MY_STACK_SIZE,
                my_entry_point, NULL, NULL, NULL,
                MY_PRIORITY, 0, 0);
```

Note

The delay parameter to *k_thread_create()* is a *k_timeout_t* value, so *K_NO_WAIT* means to start the thread immediately. The corresponding parameter to *K_THREAD_DEFINE* is a duration in integral milliseconds, so the equivalent argument is 0.

User Mode Constraints This section only applies if CONFIG_USERSPACE is enabled, and a user thread tries to create a new thread. The *k_thread_create()* API is still used, but there are additional constraints which must be met or the calling thread will be terminated:

- The calling thread must have permissions granted on both the child thread and stack parameters; both are tracked by the kernel as kernel objects.
- The child thread and stack objects must be in an uninitialized state, i.e. it is not currently running and the stack memory is unused.
- The stack size parameter passed in must be equal to or less than the bounds of the stack object when it was declared.
- The *K_USER* option must be used, as user threads can only create other user threads.
- The *K_ESSENTIAL* option must not be used, user threads may not be considered essential threads.
- The priority of the child thread must be a valid priority value, and equal to or lower than the parent thread.

Dropping Permissions If CONFIG_USERSPACE is enabled, a thread running in supervisor mode may perform a one-way transition to user mode using the *k_thread_user_mode_enter()* API. This is a one-way operation which will reset and zero the thread's stack memory. The thread will be marked as non-essential.

Terminating a Thread A thread terminates itself by returning from its entry point function.

The following code illustrates the ways a thread can terminate.

```
void my_entry_point(int unused1, int unused2, int unused3)
{
    while (1) {
        ...
        if (<some condition>) {
            return; /* thread terminates from mid-entry point function */
        }
        ...
    }

    /* thread terminates at end of entry point function */
}
```

If CONFIG_USERSPACE is enabled, aborting a thread will additionally mark the thread and stack objects as uninitialized so that they may be re-used.

Runtime Statistics Thread runtime statistics can be gathered and retrieved if CONFIG_THREAD_RUNTIME_STATS is enabled, for example, total number of execution cycles of a thread.

By default, the runtime statistics are gathered using the default kernel timer. For some architectures, SoCs or boards, there are timers with higher resolution available via timing functions. Using of these timers can be enabled via CONFIG_THREAD_RUNTIME_STATS_USE_TIMING_FUNCTIONS.

Here is an example:

```
k_thread_runtime_stats_t rt_stats_thread;

k_thread_runtime_stats_get(k_current_get(), &rt_stats_thread);

printk("Cycles: %llu\n", rt_stats_thread.execution_cycles);
```

Suggested Uses Use threads to handle processing that cannot be handled in an ISR.

Use separate threads to handle logically distinct processing operations that can execute in parallel.

Configuration Options Related configuration options:

- CONFIG_MAIN_THREAD_PRIORITY
- CONFIG_MAIN_STACK_SIZE
- CONFIG_IDLE_STACK_SIZE
- CONFIG_THREAD_CUSTOM_DATA
- CONFIG_NUM_COOP_PRIORITIES
- CONFIG_NUM_PREEMPT_PRIORITIES
- CONFIG_TIMESLICING
- CONFIG_TIMESLICE_SIZE
- CONFIG_TIMESLICE_PRIORITY
- CONFIG_USERSPACE

Related code samples

Basic Synchronization
Manipulate basic kernel synchronization primitives.

Basic thread manipulation
Spawn multiple threads that blink LEDs and print information to the console.

Dumb HTTP server (multi-threaded)
Implement a simple HTTP server supporting simultaneous connections using BSD sockets.

API Reference

group thread_apis

Defines

K_ESSENTIAL
system thread that must not abort

K_FP_IDX

FPU registers are managed by context switch.

This option indicates that the thread uses the CPU's floating point registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. No effect if CONFIG_FPU_SHARING is not enabled.

K_FP_REGS

K_USER

user mode thread

This thread has dropped from supervisor mode to user mode and consequently has additional restrictions

K_INHERIT_PERMS

Inherit Permissions.

Indicates that the thread being created should inherit all kernel object permissions from the thread that created it. No effect if CONFIG_USERSPACE is not enabled.

K_CALLBACK_STATE

Callback item state.

This is a single bit of state reserved for "callback manager" utilities (p4wq initially) who need to track operations invoked from within a user-provided callback they have been invoked. Effectively it serves as a tiny bit of zero-overhead TLS data.

K_DSP_IDX

DSP registers are managed by context switch.

This option indicates that the thread uses the CPU's DSP registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. No effect if CONFIG_DSP_SHARING is not enabled.

K_DSP_REGS

K_AGU_IDX

AGU registers are managed by context switch.

This option indicates that the thread uses the ARC processor's XY memory and DSP feature. Often used with CONFIG_ARC_AGU_SHARING . No effect if CONFIG_ARC_AGU_SHARING is not enabled.

K_AGU_REGS

K_SSE_REGS

FP and SSE registers are managed by context switch on x86.

This option indicates that the thread uses the x86 CPU's floating point and SSE registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. No effect if CONFIG_X86_SSE is not enabled.

`k_thread_access_grant`(thread, ...)

Grant a thread access to a set of kernel objects.

This is a convenience function. For the provided thread, grant access to the remaining arguments, which must be pointers to kernel objects.

The thread object must be initialized (i.e. running). The objects don't need to be. Note that NULL shouldn't be passed as an argument.

Parameters

- `thread` – Thread to grant access to objects
- `...` – list of kernel object pointers

`K_THREAD_DEFINE`(name, stack_size, entry, p1, p2, p3, prio, options, delay)

Statically define and initialize a thread.

The thread may be scheduled for immediate execution or a delayed start.

Thread options are architecture-specific, and can include K_ESSENTIAL, K_FP_REGS, and K_SSE_REGS. Multiple options may be specified by separating them using "|" (the logical OR operator).

The ID of the thread can be accessed using:

```
extern const k_tid_t <name>;
```

Note

Static threads with zero delay should not normally have MetaIRQ priority levels. This can preempt the system initialization handling (depending on the priority of the main thread) and cause surprising ordering side effects. It will not affect anything in the OS per se, but consider it bad practice. Use a SYS_INIT() callback if you need to run code before entrance to the application main().

Parameters

- `name` – Name of the thread.
- `stack_size` – Stack size in bytes.
- `entry` – Thread entry function.
- `p1` – 1st entry point parameter.
- `p2` – 2nd entry point parameter.
- `p3` – 3rd entry point parameter.
- `prio` – Thread priority.
- `options` – Thread options.
- `delay` – Scheduling delay (in milliseconds), zero for no delay.

`K_KERNEL_THREAD_DEFINE`(name, stack_size, entry, p1, p2, p3, prio, options, delay)

Statically define and initialize a thread intended to run only in kernel mode.

The thread may be scheduled for immediate execution or a delayed start.

Thread options are architecture-specific, and can include K_ESSENTIAL, K_FP_REGS, and K_SSE_REGS. Multiple options may be specified by separating them using "|" (the logical OR operator).

The ID of the thread can be accessed using:

```
extern const k_tid_t <name>;
```

Note

Threads defined by this can only run in kernel mode, and cannot be transformed into user thread via *k_thread_user_mode_enter()*.

Warning

Depending on the architecture, the stack size (`stack_size`) may need to be multiples of CONFIG_MMU_PAGE_SIZE (if MMU) or in power-of-two size (if MPU).

Parameters

- `name` – Name of the thread.
- `stack_size` – Stack size in bytes.
- `entry` – Thread entry function.
- `p1` – 1st entry point parameter.
- `p2` – 2nd entry point parameter.
- `p3` – 3rd entry point parameter.
- `prio` – Thread priority.
- `options` – Thread options.
- `delay` – Scheduling delay (in milliseconds), zero for no delay.

Typedefs

typedef void (***k_thread_user_cb_t**)(const struct *k_thread* *thread, void *user_data)

Functions

void **k_thread_foreach**(*k_thread_user_cb_t* user_cb, void *user_data)

Iterate over all the threads in the system.

This routine iterates over all the threads in the system and calls the user_cb function for each thread.

Note

`CONFIG_THREAD_MONITOR` must be set for this function to be effective.

Note

This API uses *k_spin_lock* to protect the _kernel.threads list which means creation of new threads and terminations of existing threads are blocked until this API returns.

Parameters

- `user_cb` – Pointer to the user callback function.
- `user_data` – Pointer to user data.

void `k_thread_foreach_filter_by_cpu`(unsigned int cpu, *k_thread_user_cb_t* user_cb, void *user_data)

Iterate over all the threads in running on specified cpu.

This function is does otherwise the same thing as *k_thread_foreach()*, but it only loops through the threads running on specified cpu only. If CONFIG_SMP is not defined the implementation this is the same as *k_thread_foreach()*, with an assert cpu == 0.

Note

`CONFIG_THREAD_MONITOR` must be set for this function to be effective.

Note

This API uses *k_spin_lock* to protect the _kernel.threads list which means creation of new threads and terminations of existing threads are blocked until this API returns.

Parameters

- `cpu` – The filtered cpu number
- `user_cb` – Pointer to the user callback function.
- `user_data` – Pointer to user data.

void `k_thread_foreach_unlocked`(*k_thread_user_cb_t* user_cb, void *user_data)

Iterate over all the threads in the system without locking.

This routine works exactly the same like *k_thread_foreach* but unlocks interrupts when user_cb is executed.

Note

`CONFIG_THREAD_MONITOR` must be set for this function to be effective.

Note

This API uses *k_spin_lock* only when accessing the _kernel.threads queue elements. It unlocks it during user callback function processing. If a new task is created when this `foreach` function is in progress, the added new task would not be included in the enumeration. If a task is aborted during this enumeration, there would be a race here and there is a possibility that this aborted task would be included in the enumeration.

Note

If the task is aborted and the memory occupied by its *k_thread* structure is reused when this `k_thread_foreach_unlocked` is in progress it might even lead to the system behave unstable. This function may never return, as it would follow some `next`

task pointers treating given pointer as a pointer to the *k_thread* structure while it is something different right now. Do not reuse the memory that was occupied by *k_thread* structure of aborted task if it was aborted after this function was called in any context.

Parameters

- **user_cb** – Pointer to the user callback function.
- **user_data** – Pointer to user data.

void **k_thread_foreach_unlocked_filter_by_cpu**(unsigned int cpu, *k_thread_user_cb_t* user_cb, void *user_data)

Iterate over the threads in running on current cpu without locking.

This function does otherwise the same thing as *k_thread_foreach_unlocked()*, but it only loops through the threads running on specified cpu. If CONFIG_SMP is not defined the implementation this is the same as *k_thread_foreach_unlocked()*, with an assert requiring cpu == 0.

Note

CONFIG_THREAD_MONITOR must be set for this function to be effective.

Note

This API uses *k_spin_lock* only when accessing the _kernel.threads queue elements. It unlocks it during user callback function processing. If a new task is created when this `foreach` function is in progress, the added new task would not be included in the enumeration. If a task is aborted during this enumeration, there would be a race here and there is a possibility that this aborted task would be included in the enumeration.

Note

If the task is aborted and the memory occupied by its *k_thread* structure is reused when this `k_thread_foreach_unlocked` is in progress it might even lead to the system behave unstable. This function may never return, as it would follow some `next` task pointers treating given pointer as a pointer to the *k_thread* structure while it is something different right now. Do not reuse the memory that was occupied by *k_thread* structure of aborted task if it was aborted after this function was called in any context.

Parameters

- **cpu** – The filtered cpu number
- **user_cb** – Pointer to the user callback function.
- **user_data** – Pointer to user data.

k_thread_stack_t ***k_thread_stack_alloc**(size_t size, int flags)

Dynamically allocate a thread stack.

Relevant stack creation flags include:

- *K_USER* allocate a userspace thread (requires CONFIG_USERSPACE=y)

See also

CONFIG_DYNAMIC_THREAD

Parameters

- **size** – Stack size in bytes.
- **flags** – Stack creation flags, or 0.

Return values

- **the** – allocated thread stack on success.
- **NULL** – on failure.

int **k_thread_stack_free**(k_thread_stack_t *stack)

Free a dynamically allocated thread stack.

See also

CONFIG_DYNAMIC_THREAD

Parameters

- **stack** – Pointer to the thread stack.

Return values

- **0** – on success.
- **-EBUSY** – if the thread stack is in use.
- **-EINVAL** – if stack is invalid.
- **-ENOSYS** – if dynamic thread stack allocation is disabled

k_tid_t **k_thread_create**(struct *k_thread* *new_thread, k_thread_stack_t *stack, size_t stack_size, k_thread_entry_t entry, void *p1, void *p2, void *p3, int prio, uint32_t options, *k_timeout_t* delay)

Create a thread.

This routine initializes a thread, then schedules it for execution.

The new thread may be scheduled for immediate execution or a delayed start. If the newly spawned thread does not have a delayed start the kernel scheduler may preempt the current thread to allow the new thread to execute.

Thread options are architecture-specific, and can include K_ESSENTIAL, K_FP_REGS, and K_SSE_REGS. Multiple options may be specified by separating them using "|" (the logical OR operator).

Stack objects passed to this function must be originally defined with either of these macros in order to be portable:

- *K_THREAD_STACK_DEFINE()* - For stacks that may support either user or supervisor threads.

- *K_KERNEL_STACK_DEFINE()* - For stacks that may support supervisor threads only. These stacks use less memory if CONFIG_USERSPACE is enabled.

The stack_size parameter has constraints. It must either be:

- The original size value passed to *K_THREAD_STACK_DEFINE()* or *K_KERNEL_STACK_DEFINE()*
- The return value of *K_THREAD_STACK_SIZEOF(stack)* if the stack was defined with *K_THREAD_STACK_DEFINE()*
- The return value of *K_KERNEL_STACK_SIZEOF(stack)* if the stack was defined with *K_KERNEL_STACK_DEFINE()*.

Using other values, or sizeof(stack) may produce undefined behavior.

Parameters

- `new_thread` – Pointer to uninitialized struct *k_thread*
- `stack` – Pointer to the stack space.
- `stack_size` – Stack size in bytes.
- `entry` – Thread entry function.
- `p1` – 1st entry point parameter.
- `p2` – 2nd entry point parameter.
- `p3` – 3rd entry point parameter.
- `prio` – Thread priority.
- `options` – Thread options.
- `delay` – Scheduling delay, or K_NO_WAIT (for no delay).

Returns

ID of new thread.

FUNC_NORETURN void **k_thread_user_mode_enter**(k_thread_entry_t entry, void *p1, void *p2, void *p3)

Drop a thread's privileges permanently to user mode.

This allows a supervisor thread to be re-used as a user thread. This function does not return, but control will transfer to the provided entry point as if this was a new user thread.

The implementation ensures that the stack buffer contents are erased. Any thread-local storage will be reverted to a pristine state.

Memory domain membership, resource pool assignment, kernel object permissions, priority, and thread options are preserved.

A common use of this function is to re-use the main thread as a user thread once all supervisor mode-only tasks have been completed.

Parameters

- `entry` – Function to start executing from
- `p1` – 1st entry point parameter
- `p2` – 2nd entry point parameter
- `p3` – 3rd entry point parameter

static inline void **k_thread_heap_assign**(struct *k_thread* *thread, struct *k_heap* *heap)

Assign a resource memory pool to a thread.

By default, threads have no resource pool assigned unless their parent thread has a resource pool, in which case it is inherited. Multiple threads may be assigned to the same memory pool.

Changing a thread's resource pool will not migrate allocations from the previous pool.

Parameters

- **thread** – Target thread to assign a memory pool for resource requests.
- **heap** – Heap object to use for resources, or NULL if the thread should no longer have a memory pool.

int **k_thread_join**(struct *k_thread* *thread, *k_timeout_t* timeout)

Sleep until a thread exits.

The caller will be put to sleep until the target thread exits, either due to being aborted, self-exiting, or taking a fatal error. This API returns immediately if the thread isn't running.

This API may only be called from ISRs with a K_NO_WAIT timeout, where it can be useful as a predicate to detect when a thread has aborted.

Parameters

- **thread** – Thread to wait to exit
- **timeout** – upper bound time to wait for the thread to exit.

Return values

- **0** – success, target thread has exited or wasn't running
- **-EBUSY** – returned without waiting
- **-EAGAIN** – waiting period timed out
- **-EDEADLK** – target thread is joining on the caller, or target thread is the caller

int32_t **k_sleep**(*k_timeout_t* timeout)

Put the current thread to sleep.

This routine puts the current thread to sleep for *duration*, specified as a *k_timeout_t* object.

Note

if *timeout* is set to K_FOREVER then the thread is suspended.

Parameters

- **timeout** – Desired duration of sleep.

Returns

Zero if the requested time has elapsed or if the thread was woken up by the *k_wakeup* call, the time left to sleep rounded up to the nearest millisecond.

static inline int32_t **k_msleep**(int32_t ms)

Put the current thread to sleep.

This routine puts the current thread to sleep for *duration* milliseconds.

Parameters

- **ms** – Number of milliseconds to sleep.

Returns
Zero if the requested time has elapsed or if the thread was woken up by the *k_wakeup* call, the time left to sleep rounded up to the nearest millisecond.

int32_t **k_usleep**(int32_t us)

Put the current thread to sleep with microsecond resolution.

This function is unlikely to work as expected without kernel tuning. In particular, because the lower bound on the duration of a sleep is the duration of a tick, CONFIG_SYS_CLOCK_TICKS_PER_SEC must be adjusted to achieve the resolution desired. The implications of doing this must be understood before attempting to use *k_usleep()*. Use with caution.

Parameters

- **us** – Number of microseconds to sleep.

Returns
Zero if the requested time has elapsed or if the thread was woken up by the *k_wakeup* call, the time left to sleep rounded up to the nearest microsecond.

void **k_busy_wait**(uint32_t usec_to_wait)

Cause the current thread to busy wait.

This routine causes the current thread to execute a "do nothing" loop for *usec_to_wait* microseconds.

Note

The clock used for the microsecond-resolution delay here may be skewed relative to the clock used for system timeouts like *k_sleep()*. For example k_busy_wait(1000) may take slightly more or less time than k_sleep(K_MSEC(1)), with the offset dependent on clock tolerances.

Note

In case when CONFIG_SYSTEM_CLOCK_SLOPPY_IDLE and CONFIG_PM options are enabled, this function may not work. The timer/clock used for delay processing may be disabled/inactive.

bool **k_can_yield**(void)

Check whether it is possible to yield in the current context.

This routine checks whether the kernel is in a state where it is possible to yield or call blocking API's. It should be used by code that needs to yield to perform correctly, but can feasibly be called from contexts where that is not possible. For example in the PRE_KERNEL initialization step, or when being run from the idle thread.

Returns
True if it is possible to yield in the current context, false otherwise.

void **k_yield**(void)

Yield the current thread.

This routine causes the current thread to yield execution to another thread of the same or higher priority. If there are no other ready threads of the same or higher priority, the routine returns immediately.

void **k_wakeup**(k_tid_t thread)

Wake up a sleeping thread.

This routine prematurely wakes up *thread* from sleeping.

If *thread* is not currently sleeping, the routine has no effect.

Parameters

- **thread** – ID of thread to wake.

__attribute_const__ k_tid_t **k_sched_current_thread_query**(void)

Query thread ID of the current thread.

This unconditionally queries the kernel via a system call.

Note

Use *k_current_get()* unless absolutely sure this is necessary. This should only be used directly where the thread local variable cannot be used or may contain invalid values if thread local storage (TLS) is enabled. If TLS is not enabled, this is the same as *k_current_get()*.

Returns

ID of current thread.

__attribute_const__ static inline k_tid_t **k_current_get**(void)

Get thread ID of the current thread.

Returns

ID of current thread.

void **k_thread_abort**(k_tid_t thread)

Abort a thread.

This routine permanently stops execution of *thread*. The thread is taken off all kernel queues it is part of (i.e. the ready queue, the timeout queue, or a kernel object wait queue). However, any kernel resources the thread might currently own (such as mutexes or memory blocks) are not released. It is the responsibility of the caller of this routine to ensure all necessary cleanup is performed.

After *k_thread_abort()* returns, the thread is guaranteed not to be running or to become runnable anywhere on the system. Normally this is done via blocking the caller (in the same manner as *k_thread_join()*), but in interrupt context on SMP systems the implementation is required to spin for threads that are running on other CPUs.

Parameters

- **thread** – ID of thread to abort.

void **k_thread_start**(k_tid_t thread)

Start an inactive thread.

If a thread was created with K_FOREVER in the delay parameter, it will not be added to the scheduling queue until this function is called on it.

Parameters

- **thread** – thread to start

k_ticks_t **k_thread_timeout_expires_ticks**(const struct *k_thread* *thread)

Get time when a thread wakes up, in system ticks.

This routine computes the system uptime when a waiting thread next executes, in units of system ticks. If the thread is not waiting, it returns current system time.

k_ticks_t **k_thread_timeout_remaining_ticks**(const struct *k_thread* *thread)

Get time remaining before a thread wakes up, in system ticks.

This routine computes the time remaining before a waiting thread next executes, in units of system ticks. If the thread is not waiting, it returns zero.

int **k_thread_priority_get**(k_tid_t thread)

Get a thread's priority.

This routine gets the priority of *thread*.

Parameters

- **thread** – ID of thread whose priority is needed.

Returns

Priority of *thread*.

void **k_thread_priority_set**(k_tid_t thread, int prio)

Set a thread's priority.

This routine immediately changes the priority of *thread*.

Rescheduling can occur immediately depending on the priority *thread* is set to:

- If its priority is raised above the priority of the caller of this function, and the caller is preemptible, *thread* will be scheduled in.
- If the caller operates on itself, it lowers its priority below that of other threads in the system, and the caller is preemptible, the thread of highest priority will be scheduled in.

Priority can be assigned in the range of -CONFIG_NUM_COOP_PRIORITIES to CONFIG_NUM_PREEMPT_PRIORITIES-1, where -CONFIG_NUM_COOP_PRIORITIES is the highest priority.

Warning

Changing the priority of a thread currently involved in mutex priority inheritance may result in undefined behavior.

Parameters

- **thread** – ID of thread whose priority is to be set.
- **prio** – New priority.

void **k_thread_deadline_set**(k_tid_t thread, int deadline)

Set deadline expiration time for scheduler.

This sets the "deadline" expiration as a time delta from the current time, in the same units used by *k_cycle_get_32()*. The scheduler (when deadline scheduling is enabled) will choose the next expiring thread when selecting between threads at the same static priority. Threads at different priorities will be scheduled according to their static priority.

Note

Deadlines are stored internally using 32 bit unsigned integers. The number of cycles between the "first" deadline in the scheduler queue and the "last" deadline

must be less than 2^31 (i.e a signed non-negative quantity). Failure to adhere to this rule may result in scheduled threads running in an incorrect deadline order.

Note

Despite the API naming, the scheduler makes no guarantees the thread WILL be scheduled within that deadline, nor does it take extra metadata (like e.g. the "run-time" and "period" parameters in Linux sched_setattr()) that allows the kernel to validate the scheduling for achievability. Such features could be implemented above this call, which is simply input to the priority selection logic.

Note

You should enable `CONFIG_SCHED_DEADLINE` in your project configuration.

Parameters

- **thread** – A thread on which to set the deadline
- **deadline** – A time delta, in cycle units

int **k_thread_cpu_mask_clear**(k_tid_t thread)

Sets all CPU enable masks to zero.

After this returns, the thread will no longer be schedulable on any CPUs. The thread must not be currently runnable.

Note

You should enable `CONFIG_SCHED_CPU_MASK` in your project configuration.

Parameters

- **thread** – Thread to operate upon

Returns

Zero on success, otherwise error code

int **k_thread_cpu_mask_enable_all**(k_tid_t thread)

Sets all CPU enable masks to one.

After this returns, the thread will be schedulable on any CPU. The thread must not be currently runnable.

Note

You should enable `CONFIG_SCHED_CPU_MASK` in your project configuration.

Parameters

- **thread** – Thread to operate upon

Returns

Zero on success, otherwise error code

int **k_thread_cpu_mask_enable**(k_tid_t thread, int cpu)

Enable thread to run on specified CPU.

The thread must not be currently runnable.

> **Note**
>
> You should enable CONFIG_SCHED_CPU_MASK in your project configuration.

Parameters

- **thread** – Thread to operate upon
- **cpu** – CPU index

Returns

Zero on success, otherwise error code

int **k_thread_cpu_mask_disable**(k_tid_t thread, int cpu)

Prevent thread to run on specified CPU.

The thread must not be currently runnable.

> **Note**
>
> You should enable CONFIG_SCHED_CPU_MASK in your project configuration.

Parameters

- **thread** – Thread to operate upon
- **cpu** – CPU index

Returns

Zero on success, otherwise error code

int **k_thread_cpu_pin**(k_tid_t thread, int cpu)

Pin a thread to a CPU.

Pin a thread to a CPU by first clearing the cpu mask and then enabling the thread on the selected CPU.

Parameters

- **thread** – Thread to operate upon
- **cpu** – CPU index

Returns

Zero on success, otherwise error code

void **k_thread_suspend**(k_tid_t thread)

Suspend a thread.

This routine prevents the kernel scheduler from making *thread* the current thread. All other internal operations on *thread* are still performed; for example, kernel objects it is waiting on are still handed to it. Note that any existing timeouts (e.g. *k_sleep()*, or a timeout argument to *k_sem_take()* et. al.) will be canceled. On resume, the thread will begin running immediately and return from the blocked call.

When the target thread is active on another CPU, the caller will block until the target thread is halted (suspended or aborted). But if the caller is in an interrupt context, it will spin waiting for that target thread active on another CPU to halt.

If *thread* is already suspended, the routine has no effect.

Parameters

- `thread` – ID of thread to suspend.

void `k_thread_resume`(k_tid_t thread)

Resume a suspended thread.

This routine allows the kernel scheduler to make *thread* the current thread, when it is next eligible for that role.

If *thread* is not currently suspended, the routine has no effect.

Parameters

- `thread` – ID of thread to resume.

void `k_sched_time_slice_set`(int32_t slice, int prio)

Set time-slicing period and scope.

This routine specifies how the scheduler will perform time slicing of preemptible threads.

To enable time slicing, *slice* must be non-zero. The scheduler ensures that no thread runs for more than the specified time limit before other threads of that priority are given a chance to execute. Any thread whose priority is higher than *prio* is exempted, and may execute as long as desired without being preempted due to time slicing.

Time slicing only limits the maximum amount of time a thread may continuously execute. Once the scheduler selects a thread for execution, there is no minimum guaranteed time the thread will execute before threads of greater or equal priority are scheduled.

When the current thread is the only one of that priority eligible for execution, this routine has no effect; the thread is immediately rescheduled after the slice period expires.

To disable timeslicing, set both *slice* and *prio* to zero.

Parameters

- `slice` – Maximum time slice length (in milliseconds).
- `prio` – Highest thread priority level eligible for time slicing.

void `k_thread_time_slice_set`(struct *k_thread* *th, int32_t slice_ticks,
k_thread_timeslice_fn_t expired, void *data)

Set thread time slice.

As for k_sched_time_slice_set, but (when CONFIG_TIMESLICE_PER_THREAD=y) sets the timeslice for a specific thread. When non-zero, this timeslice will take precedence over the global value.

When such a thread's timeslice expires, the configured callback will be called before the thread is removed/re-added to the run queue. This callback will occur in interrupt context, and the specified thread is guaranteed to have been preempted by the currently-executing ISR. Such a callback is free to, for example, modify the thread priority or slice time for future execution, suspend the thread, etc...

Note

Unlike the older API, the time slice parameter here is specified in ticks, not milliseconds. Ticks have always been the internal unit, and not all platforms have integer conversions between the two.

Note

Threads with a non-zero slice time set will be timesliced always, even if they are higher priority than the maximum timeslice priority set via *k_sched_time_slice_set()*.

Note

The callback notification for slice expiration happens, as it must, while the thread is still "current", and thus it happens before any registered timeouts at this tick. This has the somewhat confusing side effect that the tick time (c.f. *k_uptime_get()*) does not yet reflect the expired ticks. Applications wishing to make fine-grained timing decisions within this callback should use the cycle API, or derived facilities like k_thread_runtime_stats_get().

Parameters

- `th` – A valid, initialized thread
- `slice_ticks` – Maximum timeslice, in ticks
- `expired` – Callback function called on slice expiration
- `data` – Parameter for the expiration handler

void `k_sched_lock`(void)

Lock the scheduler.

This routine prevents the current thread from being preempted by another thread by instructing the scheduler to treat it as a cooperative thread. If the thread subsequently performs an operation that makes it unready, it will be context switched out in the normal manner. When the thread again becomes the current thread, its non-preemptible status is maintained.

This routine can be called recursively.

Owing to clever implementation details, scheduler locks are extremely fast for non-userspace threads (just one byte inc/decrement in the thread struct).

Note

This works by elevating the thread priority temporarily to a cooperative priority, allowing cheap synchronization vs. other preemptible or cooperative threads running on the current CPU. It does not prevent preemption or asynchrony of other types. It does not prevent threads from running on other CPUs when CONFIG_SMP=y. It does not prevent interrupts from happening, nor does it prevent threads with MetaIRQ priorities from preempting the current thread. In general this is a historical API not well-suited to modern applications, use with care.

void `k_sched_unlock`(void)

Unlock the scheduler.

This routine reverses the effect of a previous call to *k_sched_lock()*. A thread must call the routine once for each time it called *k_sched_lock()* before the thread becomes preemptible.

void k_thread_custom_data_set(void *value)

Set current thread's custom data.

This routine sets the custom data for the current thread to @ value.

Custom data is not used by the kernel itself, and is freely available for a thread to use as it sees fit. It can be used as a framework upon which to build thread-local storage.

Parameters

- value – New custom data value.

void *k_thread_custom_data_get(void)

Get current thread's custom data.

This routine returns the custom data for the current thread.

Returns

Current custom data value.

int k_thread_name_set(k_tid_t thread, const char *str)

Set current thread name.

Set the name of the thread to be used when CONFIG_THREAD_MONITOR is enabled for tracing and debugging.

Parameters

- thread – Thread to set name, or NULL to set the current thread
- str – Name string

Return values

- 0 – on success
- -EFAULT – Memory access error with supplied string
- -ENOSYS – Thread name configuration option not enabled
- -EINVAL – Thread name too long

const char *k_thread_name_get(k_tid_t thread)

Get thread name.

Get the name of a thread

Parameters

- thread – Thread ID

Return values

Thread – name, or NULL if configuration not enabled

int k_thread_name_copy(k_tid_t thread, char *buf, size_t size)

Copy the thread name into a supplied buffer.

Parameters

- thread – Thread to obtain name information
- buf – Destination buffer
- size – Destination buffer size

Return values

- -ENOSPC – Destination buffer too small
- -EFAULT – Memory access error
- -ENOSYS – Thread name feature not enabled

- **0** – Success

const char *k_thread_state_str(k_tid_t thread_id, char *buf, size_t buf_size)

Get thread state string.

This routine generates a human friendly string containing the thread's state, and copies as much of it as possible into *buf*.

Parameters

- **thread_id** – Thread ID
- **buf** – Buffer into which to copy state strings
- **buf_size** – Size of the buffer

Return values

Pointer – to *buf* if data was copied, else a pointer to "".

struct k_thread

#include <thread.h> Thread Structure.

Public Members

struct _callee_saved **callee_saved**

defined by the architecture, but all archs need these

void ***init_data**

static thread init data

_wait_q_t **join_queue**

threads waiting in *k_thread_join()*

struct __thread_entry **entry**

thread entry and parameters description

struct *k_thread* ***next_thread**

next item in list of all threads

void ***custom_data**

crude thread-local storage

struct _thread_stack_info **stack_info**

Stack Info.

struct _mem_domain_info **mem_domain_info**

memory domain info of the thread

k_thread_stack_t ***stack_obj**

Base address of thread stack.

If memory mapped stack (CONFIG_THREAD_STACK_MEM_MAPPED) is enabled, this is the physical address of the stack.

void *syscall_frame
: current syscall frame pointer

int swap_retval
: z_swap() return value

void *switch_handle
: Context handle returned via *arch_switch()*

struct *k_heap* *resource_pool
: resource pool

_wait_q_t halt_queue
: threads waiting in *k_thread_suspend()*

struct _thread_arch arch
: arch-specifics: must always be at the end

group thread_stack_api
: Thread Stack APIs.

Defines

K_KERNEL_STACK_DECLARE(sym, size)
: Declare a reference to a thread stack.

  This macro declares the symbol of a thread stack defined elsewhere in the current scope.

  Parameters

  - sym – Thread stack symbol name
  - size – Size of the stack memory region

K_KERNEL_STACK_ARRAY_DECLARE(sym, nmemb, size)
: Declare a reference to a thread stack array.

  This macro declares the symbol of a thread stack array defined elsewhere in the current scope.

  Parameters

  - sym – Thread stack symbol name
  - nmemb – Number of stacks defined
  - size – Size of the stack memory region

K_KERNEL_PINNED_STACK_ARRAY_DECLARE(sym, nmemb, size)
: Declare a reference to a pinned thread stack array.

  This macro declares the symbol of a pinned thread stack array defined elsewhere in the current scope.

  Parameters

  - sym – Thread stack symbol name
  - nmemb – Number of stacks defined

- **size** – Size of the stack memory region

K_KERNEL_STACK_DEFINE(sym, size)

Define a toplevel kernel stack memory region.

This defines a region of memory for use as a thread stack, for threads that exclusively run in supervisor mode. This is also suitable for declaring special stacks for interrupt or exception handling.

Stacks defined with this macro may not host user mode threads.

It is legal to precede this definition with the 'static' keyword.

It is NOT legal to take the sizeof(sym) and pass that to the stackSize parameter of *k_thread_create()*, it may not be the same as the 'size' parameter. Use *K_KERNEL_STACK_SIZEOF()* instead.

The total amount of memory allocated may be increased to accommodate fixed-size stack overflow guards.

Parameters

- **sym** – Thread stack symbol name
- **size** – Size of the stack memory region

K_KERNEL_PINNED_STACK_DEFINE(sym, size)

Define a toplevel kernel stack memory region in pinned section.

See *K_KERNEL_STACK_DEFINE()* for more information and constraints.

This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as *K_KERNEL_STACK_DEFINE()*.

Parameters

- **sym** – Thread stack symbol name
- **size** – Size of the stack memory region

K_KERNEL_STACK_ARRAY_DEFINE(sym, nmemb, size)

Define a toplevel array of kernel stack memory regions.

Stacks defined with this macro may not host user mode threads.

Parameters

- **sym** – Kernel stack array symbol name
- **nmemb** – Number of stacks to define
- **size** – Size of the stack memory region

K_KERNEL_PINNED_STACK_ARRAY_DEFINE(sym, nmemb, size)

Define a toplevel array of kernel stack memory regions in pinned section.

See *K_KERNEL_STACK_ARRAY_DEFINE()* for more information and constraints.

This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as *K_KERNEL_STACK_ARRAY_DEFINE()*.

Parameters

- **sym** – Kernel stack array symbol name
- **nmemb** – Number of stacks to define
- **size** – Size of the stack memory region

K_KERNEL_STACK_MEMBER(sym, size)

Define an embedded stack memory region.

Used for kernel stacks embedded within other data structures.

Stacks defined with this macro may not host user mode threads.

Parameters

- **sym** – Thread stack symbol name
- **size** – Size of the stack memory region

K_KERNEL_STACK_SIZEOF(sym)

K_THREAD_STACK_DECLARE(sym, size)

Declare a reference to a thread stack.

This macro declares the symbol of a thread stack defined elsewhere in the current scope.

Parameters

- **sym** – Thread stack symbol name
- **size** – Size of the stack memory region

K_THREAD_STACK_ARRAY_DECLARE(sym, nmemb, size)

Declare a reference to a thread stack array.

This macro declares the symbol of a thread stack array defined elsewhere in the current scope.

Parameters

- **sym** – Thread stack symbol name
- **nmemb** – Number of stacks defined
- **size** – Size of the stack memory region

K_THREAD_STACK_SIZEOF(sym)

Return the size in bytes of a stack memory region.

Convenience macro for passing the desired stack size to *k_thread_create()* since the underlying implementation may actually create something larger (for instance a guard area).

The value returned here is not guaranteed to match the 'size' parameter passed to K_THREAD_STACK_DEFINE and may be larger, but is always safe to pass to *k_thread_create()* for the associated stack object.

Parameters

- **sym** – Stack memory symbol

Returns

Size of the stack buffer

K_THREAD_STACK_DEFINE(sym, size)

Define a toplevel thread stack memory region.

This defines a region of memory suitable for use as a thread's stack.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in 'noinit' section so that it isn't zeroed at boot

The defined symbol will always be a k_thread_stack_t which can be passed to *k_thread_create()*, but should otherwise not be manipulated. If the buffer inside needs

to be examined, examine thread->stack_info for the associated thread object to obtain the boundaries.

It is legal to precede this definition with the 'static' keyword.

It is NOT legal to take the sizeof(sym) and pass that to the stackSize parameter of *k_thread_create()*, it may not be the same as the 'size' parameter. Use *K_THREAD_STACK_SIZEOF()* instead.

Some arches may round the size of the usable stack region up to satisfy alignment constraints. *K_THREAD_STACK_SIZEOF()* will return the aligned size.

Parameters

- **sym** – Thread stack symbol name
- **size** – Size of the stack memory region

`K_THREAD_PINNED_STACK_DEFINE`(sym, size)

Define a toplevel thread stack memory region in pinned section.

This defines a region of memory suitable for use as a thread's stack.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in 'noinit' section so that it isn't zeroed at boot

The defined symbol will always be a k_thread_stack_t which can be passed to *k_thread_create()*, but should otherwise not be manipulated. If the buffer inside needs to be examined, examine thread->stack_info for the associated thread object to obtain the boundaries.

It is legal to precede this definition with the 'static' keyword.

It is NOT legal to take the sizeof(sym) and pass that to the stackSize parameter of *k_thread_create()*, it may not be the same as the 'size' parameter. Use *K_THREAD_STACK_SIZEOF()* instead.

Some arches may round the size of the usable stack region up to satisfy alignment constraints. *K_THREAD_STACK_SIZEOF()* will return the aligned size.

This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as *K_THREAD_STACK_DEFINE()*.

Parameters

- **sym** – Thread stack symbol name
- **size** – Size of the stack memory region

`K_THREAD_STACK_LEN`(size)

Calculate size of stacks to be allocated in a stack array.

This macro calculates the size to be allocated for the stacks inside a stack array. It accepts the indicated "size" as a parameter and if required, pads some extra bytes (e.g. for MPU scenarios). Refer K_THREAD_STACK_ARRAY_DEFINE definition to see how this is used. The returned size ensures each array member will be aligned to the required stack base alignment.

Parameters

- **size** – Size of the stack memory region

Returns

Appropriate size for an array member

K_THREAD_STACK_ARRAY_DEFINE(sym, nmemb, size)

Define a toplevel array of thread stack memory regions.

Create an array of equally sized stacks. See K_THREAD_STACK_DEFINE definition for additional details and constraints.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in 'noinit' section so that it isn't zeroed at boot

Parameters

- **sym** – Thread stack symbol name
- **nmemb** – Number of stacks to define
- **size** – Size of the stack memory region

K_THREAD_PINNED_STACK_ARRAY_DEFINE(sym, nmemb, size)

Define a toplevel array of thread stack memory regions in pinned section.

Create an array of equally sized stacks. See K_THREAD_STACK_DEFINE definition for additional details and constraints.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in 'noinit' section so that it isn't zeroed at boot

This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as *K_THREAD_STACK_DEFINE()*.

Parameters

- **sym** – Thread stack symbol name
- **nmemb** – Number of stacks to define
- **size** – Size of the stack memory region

K_THREAD_STACK_MEMBER(sym, size)

Define an embedded stack memory region.

Used for stacks embedded within other data structures. Use is highly discouraged but in some cases necessary. For memory protection scenarios, it is very important that any RAM preceding this member not be writable by threads else a stack overflow will lead to silent corruption. In other words, the containing data structure should live in RAM owned by the kernel.

A user thread can only be started with a stack defined in this way if the thread starting it is in supervisor mode.

Deprecated:

This is now deprecated, as stacks defined in this way are not usable from user mode. Use K_KERNEL_STACK_MEMBER.

Parameters

- **sym** – Thread stack symbol name
- **size** – Size of the stack memory region

Scheduling

The kernel's priority-based scheduler allows an application's threads to share the CPU.

Concepts The scheduler determines which thread is allowed to execute at any point in time; this thread is known as the **current thread**.

There are various points in time when the scheduler is given an opportunity to change the identity of the current thread. These points are called **reschedule points**. Some potential reschedule points are:

- transition of a thread from running state to a suspended or waiting state, for example by *k_sem_take()* or *k_sleep()*.
- transition of a thread to the *ready state*, for example by *k_sem_give()* or *k_thread_start()*
- return to thread context after processing an interrupt
- when a running thread invokes *k_yield()*

A thread **sleeps** when it voluntarily initiates an operation that transitions itself to a suspended or waiting state.

Whenever the scheduler changes the identity of the current thread, or when execution of the current thread is replaced by an ISR, the kernel first saves the current thread's CPU register values. These register values get restored when the thread later resumes execution.

Scheduling Algorithm The kernel's scheduler selects the highest priority ready thread to be the current thread. When multiple ready threads of the same priority exist, the scheduler chooses the one that has been waiting longest.

A thread's relative priority is primarily determined by its static priority. However, when both earliest-deadline-first scheduling is enabled (CONFIG_SCHED_DEADLINE) and a choice of threads have equal static priority, then the thread with the earlier deadline is considered to have the higher priority. Thus, when earliest-deadline-first scheduling is enabled, two threads are only considered to have the same priority when both their static priorities and deadlines are equal. The routine *k_thread_deadline_set()* is used to set a thread's deadline.

Note

Execution of ISRs takes precedence over thread execution, so the execution of the current thread may be replaced by an ISR at any time unless interrupts have been masked. This applies to both cooperative threads and preemptive threads.

The kernel can be built with one of several choices for the ready queue implementation, offering different choices between code size, constant factor runtime overhead and performance scaling when many threads are added.

- Simple linked-list ready queue (CONFIG_SCHED_DUMB)

  The scheduler ready queue will be implemented as a simple unordered list, with very fast constant time performance for single threads and very low code size. This implementation should be selected on systems with constrained code size that will never see more than a small number (3, maybe) of runnable threads in the queue at any given time. On most platforms (that are not otherwise using the red/black tree) this results in a savings of ~2k of code size.

- Red/black tree ready queue (CONFIG_SCHED_SCALABLE)

  The scheduler ready queue will be implemented as a red/black tree. This has rather slower constant-time insertion and removal overhead, and on most platforms (that are not otherwise using the red/black tree somewhere) requires an extra ~2kb of code. The resulting behavior will scale cleanly and quickly into the many thousands of threads.

  Use this for applications needing many concurrent runnable threads (> 20 or so). Most applications won't need this ready queue implementation.

- Traditional multi-queue ready queue (CONFIG_SCHED_MULTIQ)

  When selected, the scheduler ready queue will be implemented as the classic/textbook array of lists, one per priority.

  This corresponds to the scheduler algorithm used in Zephyr versions prior to 1.12.

  It incurs only a tiny code size overhead vs. the "dumb" scheduler and runs in O(1) time in almost all circumstances with very low constant factor. But it requires a fairly large RAM budget to store those list heads, and the limited features make it incompatible with features like deadline scheduling that need to sort threads more finely, and SMP affinity which need to traverse the list of threads.

  Typical applications with small numbers of runnable threads probably want the DUMB scheduler.

The wait_q abstraction used in IPC primitives to pend threads for later wakeup shares the same backend data structure choices as the scheduler, and can use the same options.

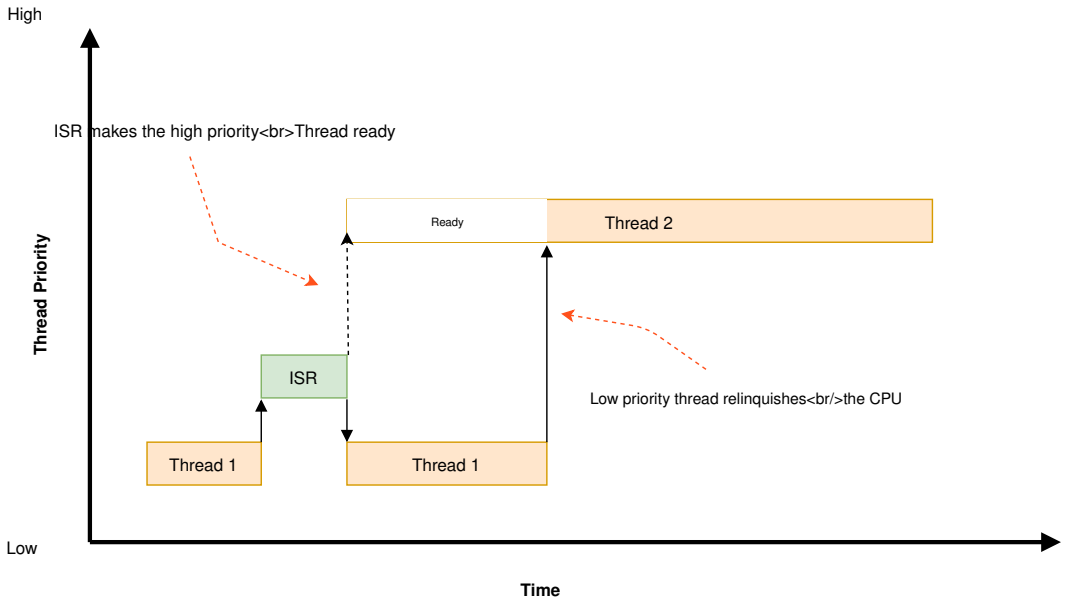
- Scalable wait_q implementation (CONFIG_WAITQ_SCALABLE)

  When selected, the wait_q will be implemented with a balanced tree. Choose this if you expect to have many threads waiting on individual primitives. There is a ~2kb code size increase over CONFIG_WAITQ_DUMB (which may be shared with CONFIG_SCHED_SCALABLE) if the red/black tree is not used elsewhere in the application, and pend/unpend operations on "small" queues will be somewhat slower (though this is not generally a performance path).

- Simple linked-list wait_q (CONFIG_WAITQ_DUMB)

  When selected, the wait_q will be implemented with a doubly-linked list. Choose this if you expect to have only a few threads blocked on any single IPC primitive.

Cooperative Time Slicing Once a cooperative thread becomes the current thread, it remains the current thread until it performs an action that makes it unready. Consequently, if a cooperative thread performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads, including those of higher priority and equal priority.



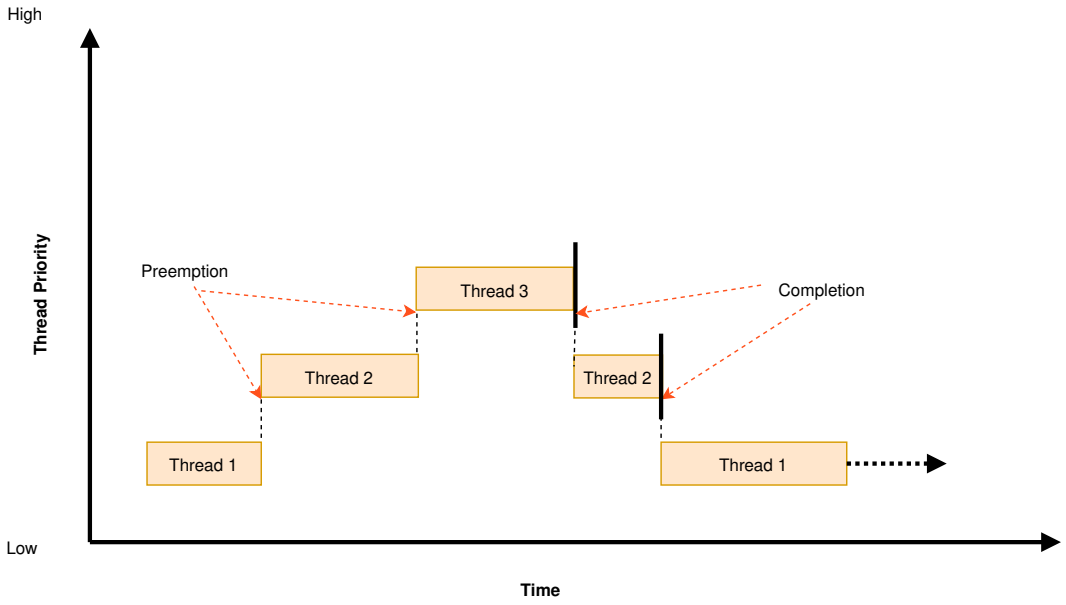
To overcome such problems, a cooperative thread can voluntarily relinquish the CPU from time to time to permit other threads to execute. A thread can relinquish the CPU in two ways:

- Calling *k_yield()* puts the thread at the back of the scheduler's prioritized list of ready threads, and then invokes the scheduler. All ready threads whose priority is higher or equal to that of the yielding thread are then allowed to execute before the yielding thread

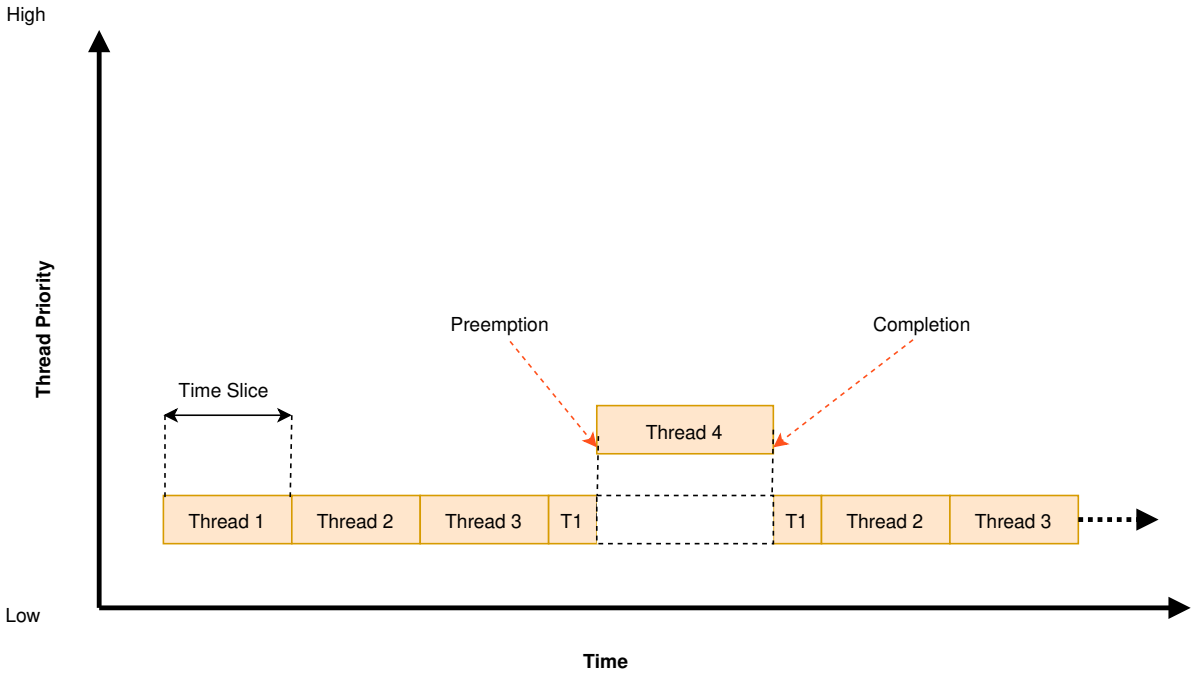
is rescheduled. If no such ready threads exist, the scheduler immediately reschedules the yielding thread without context switching.

- Calling `k_sleep()` makes the thread unready for a specified time period. Ready threads of *all* priorities are then allowed to execute; however, there is no guarantee that threads whose priority is lower than that of the sleeping thread will actually be scheduled before the sleeping thread becomes ready once again.

Preemptive Time Slicing Once a preemptive thread becomes the current thread, it remains the current thread until a higher priority thread becomes ready, or until the thread performs an action that makes it unready. Consequently, if a preemptive thread performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads, including those of equal priority.



To overcome such problems, a preemptive thread can perform cooperative time slicing (as described above), or the scheduler's time slicing capability can be used to allow other threads of the same priority to execute.



The scheduler divides time into a series of **time slices**, where slices are measured in system clock ticks. The time slice size is configurable, but this size can be changed while the application is running.

At the end of every time slice, the scheduler checks to see if the current thread is preemptible and, if so, implicitly invokes `k_yield()` on behalf of the thread. This gives other ready threads of the same priority the opportunity to execute before the current thread is scheduled again. If no threads of equal priority are ready, the current thread remains the current thread.

Threads with a priority higher than specified limit are exempt from preemptive time slicing, and are never preempted by a thread of equal priority. This allows an application to use preemptive time slicing only when dealing with lower priority threads that are less time-sensitive.

Note

The kernel's time slicing algorithm does *not* ensure that a set of equal-priority threads receive an equitable amount of CPU time, since it does not measure the amount of time a thread actually gets to execute. However, the algorithm *does* ensure that a thread never executes for longer than a single time slice without being required to yield.

Scheduler Locking A preemptible thread that does not wish to be preempted while performing a critical operation can instruct the scheduler to temporarily treat it as a cooperative thread by calling `k_sched_lock()`. This prevents other threads from interfering while the critical operation is being performed.

Once the critical operation is complete the preemptible thread must call `k_sched_unlock()` to restore its normal, preemptible status.

If a thread calls `k_sched_lock()` and subsequently performs an action that makes it unready, the scheduler will switch the locking thread out and allow other threads to execute. When the locking thread again becomes the current thread, its non-preemptible status is maintained.

Note

Locking out the scheduler is a more efficient way for a preemptible thread to prevent preemption than changing its priority level to a negative value.

Thread Sleeping A thread can call *k_sleep()* to delay its processing for a specified time period. During the time the thread is sleeping the CPU is relinquished to allow other ready threads to execute. Once the specified delay has elapsed the thread becomes ready and is eligible to be scheduled once again.

A sleeping thread can be woken up prematurely by another thread using *k_wakeup()*. This technique can sometimes be used to permit the secondary thread to signal the sleeping thread that something has occurred *without* requiring the threads to define a kernel synchronization object, such as a semaphore. Waking up a thread that is not sleeping is allowed, but has no effect.

Busy Waiting A thread can call *k_busy_wait()* to perform a `busy wait` that delays its processing for a specified time period *without* relinquishing the CPU to another ready thread.

A busy wait is typically used instead of thread sleeping when the required delay is too short to warrant having the scheduler context switch from the current thread to another thread and then back again.

Suggested Uses Use cooperative threads for device drivers and other performance-critical work.

Use cooperative threads to implement mutually exclusion without the need for a kernel object, such as a mutex.

Use preemptive threads to give priority to time-sensitive processing over less time-sensitive processing.

CPU Idling

Although normally reserved for the idle thread, in certain special applications, a thread might want to make the CPU idle.

- *Concepts*
- *Implementation*
  - *Making the CPU idle*
  - *Making the CPU idle in an atomic fashion*
- *Suggested Uses*
- *API Reference*

Concepts Making the CPU idle causes the kernel to pause all operations until an event, normally an interrupt, wakes up the CPU. In a regular system, the idle thread is responsible for this. However, in some constrained systems, it is possible that another thread takes this duty.

Implementation

Making the CPU idle Making the CPU idle is simple: call the k_cpu_idle() API. The CPU will stop executing instructions until an event occurs. Most likely, the function will be called within a loop. Note that in certain architectures, upon return, k_cpu_idle() unconditionally unmasks interrupts.

```
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}

int main(void)
{
    k_sem_init(&my_sem, 0, 1);

    /* wait for semaphore from ISR, then do related work */

    for (;;) {

        /* wait for ISR to trigger work to perform */
        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {

            /* ... do processing */

        }

        /* put CPU to sleep to save power */
        k_cpu_idle();
    }
}
```

Making the CPU idle in an atomic fashion It is possible that there is a need to do some work atomically before making the CPU idle. In such a case, k_cpu_atomic_idle() should be used instead.

In fact, there is a race condition in the previous example: the interrupt could occur between the time the semaphore is taken, finding out it is not available and making the CPU idle again. In some systems, this can cause the CPU to idle until *another* interrupt occurs, which might be *never*, thus hanging the system completely. To prevent this, k_cpu_atomic_idle() should have been used, like in this example.

```
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}

int main(void)
{
    k_sem_init(&my_sem, 0, 1);

    for (;;) {

        unsigned int key = irq_lock();

        /*
         * Wait for semaphore from ISR; if acquired, do related work, then
         * go to next loop iteration (the semaphore might have been given
         * again); else, make the CPU idle.
```

(continues on next page)

(continued from previous page)

```
         */

        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {

            irq_unlock(key);

            /* ... do processing */

        } else {
            /* put CPU to sleep to save power */
            k_cpu_atomic_idle(key);
        }
    }
}
```

Suggested Uses Use k_cpu_atomic_idle() when a thread has to do some real work in addition to idling the CPU to wait for an event. See example above.

Use k_cpu_idle() only when a thread is only responsible for idling the CPU, i.e. not doing any real work, like in this example below.

```
int main(void)
{
    /* ... do some system/application initialization */

    /* thread is only used for CPU idling from this point on */
    for (;;) {
        k_cpu_idle();
    }
}
```

Note

Do not use these APIs unless absolutely necessary. In a normal system, the idle thread takes care of power management, including CPU idling.

API Reference

group `cpu_idle_apis`

Functions

static inline void **k_cpu_idle**(void)

Make the CPU idle.

This function makes the CPU idle until an event wakes it up.

In a regular system, the idle thread should be the only thread responsible for making the CPU idle and triggering any type of power management. However, in some more constrained systems, such as a single-threaded system, the only thread would be responsible for this if needed.

> **Note**
>
> In some architectures, before returning, the function unmasks interrupts unconditionally.

static inline void **k_cpu_atomic_idle**(unsigned int key)

Make the CPU idle in an atomic fashion.

Similar to *k_cpu_idle()*, but must be called with interrupts locked.

Enabling interrupts and entering a low-power mode will be atomic, i.e. there will be no period of time where interrupts are enabled before the processor enters a low-power mode.

After waking up from the low-power mode, the interrupt lockout state will be restored as if by *irq_unlock(key)*.

Parameters

- **key** – Interrupt locking key obtained from *irq_lock()*.

System Threads

- *Implementation*
  - *Writing a main() function*
- *Suggested Uses*

A *system thread* is a thread that the kernel spawns automatically during system initialization.

The kernel spawns the following system threads:

Main thread
: This thread performs kernel initialization, then calls the application's `main()` function (if one is defined).

  By default, the main thread uses the highest configured preemptible thread priority (i.e. 0). If the kernel is not configured to support preemptible threads, the main thread uses the lowest configured cooperative thread priority (i.e. -1).

  The main thread is an essential thread while it is performing kernel initialization or executing the application's `main()` function; this means a fatal system error is raised if the thread aborts. If `main()` is not defined, or if it executes and then does a normal return, the main thread terminates normally and no error is raised.

Idle thread
: This thread executes when there is no other work for the system to do. If possible, the idle thread activates the board's power management support to save power; otherwise, the idle thread simply performs a "do nothing" loop. The idle thread remains in existence as long as the system is running and never terminates.

  The idle thread always uses the lowest configured thread priority. If this makes it a cooperative thread, the idle thread repeatedly yields the CPU to allow the application's other threads to run when they need to.

  The idle thread is an essential thread, which means a fatal system error is raised if the thread aborts.

Additional system threads may also be spawned, depending on the kernel and board configuration options specified by the application. For example, enabling the system workqueue spawns a system thread that services the work items submitted to it. (See *Workqueue Threads*.)

Implementation

Writing a main() function An application-supplied `main()` function begins executing once kernel initialization is complete. The kernel does not pass any arguments to the function.

The following code outlines a trivial `main()` function. The function used by a real application can be as complex as needed.

```
int main(void)
{
    /* initialize a semaphore */
    ...

    /* register an ISR that gives the semaphore */
    ...

    /* monitor the semaphore forever */
    while (1) {
        /* wait for the semaphore to be given by the ISR */
        ...
        /* do whatever processing is now needed */
        ...
    }
}
```

Suggested Uses Use the main thread to perform thread-based processing in an application that only requires a single thread, rather than defining an additional application-specific thread.

Workqueue Threads

- *Work Item Lifecycle*
- *Delayable Work*
- *Triggered Work*
- *System Workqueue*
- *How to Use Workqueues*
- *Workqueue Best Practices*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

A *workqueue* is a kernel object that uses a dedicated thread to process work items in a first in, first out manner. Each work item is processed by calling the function specified by the work item. A workqueue is typically used by an ISR or a high-priority thread to offload non-urgent processing to a lower-priority thread so it does not impact time-sensitive processing.

Any number of workqueues can be defined (limited only by available RAM). Each workqueue is referenced by its memory address.

A workqueue has the following key properties:

- A **queue** of work items that have been added, but not yet processed.
- A **thread** that processes the work items in the queue. The priority of the thread is configurable, allowing it to be either cooperative or preemptive as required.

Regardless of workqueue thread priority the workqueue thread will yield between each submitted work item, to prevent a cooperative workqueue from starving other threads.

A workqueue must be initialized before it can be used. This sets its queue to empty and spawns the workqueue's thread. The thread runs forever, but sleeps when no work items are available.

Note

The behavior described here is changed from the Zephyr workqueue implementation used prior to release 2.6. Among the changes are:

- Precise tracking of the status of cancelled work items, so that the caller need not be concerned that an item may be processing when the cancellation returns. Checking of return values on cancellation is still required.
- Direct submission of delayable work items to the queue with *K_NO_WAIT* rather than always going through the timeout API, which could introduce delays.
- The ability to wait until a work item has completed or a queue has been drained.
- Finer control of behavior when scheduling a delayable work item, specifically allowing a previous deadline to remain unchanged when a work item is scheduled again.
- Safe handling of work item resubmission when the item is being processed on another workqueue.

Using the return values of *k_work_busy_get()* or *k_work_is_pending()*, or measurements of remaining time until delayable work is scheduled, should be avoided to prevent race conditions of the type observed with the previous implementation. See also *Workqueue Best Practices*.

Work Item Lifecycle Any number of **work items** can be defined. Each work item is referenced by its memory address.

A work item is assigned a **handler function**, which is the function executed by the workqueue's thread when the work item is processed. This function accepts a single argument, which is the address of the work item itself. The work item also maintains information about its status.

A work item must be initialized before it can be used. This records the work item's handler function and marks it as not pending.

A work item may be **queued** (K_WORK_QUEUED) by submitting it to a workqueue by an ISR or a thread. Submitting a work item appends the work item to the workqueue's queue. Once the workqueue's thread has processed all of the preceding work items in its queue the thread will remove the next work item from the queue and invoke the work item's handler function. Depending on the scheduling priority of the workqueue's thread, and the work required by other items in the queue, a queued work item may be processed quickly or it may remain in the queue for an extended period of time.

A delayable work item may be **scheduled** (K_WORK_DELAYED) to a workqueue; see *Delayable Work*.

A work item will be **running** (K_WORK_RUNNING) when it is running on a work queue, and may also be **canceling** (K_WORK_CANCELING) if it started running before a thread has requested that it be cancelled.

A work item can be in multiple states; for example it can be:

- running on a queue;
- marked canceling (because a thread used *k_work_cancel_sync()* to wait until the work item completed);
- queued to run again on the same queue;
- scheduled to be submitted to a (possibly different) queue

all simultaneously. A work item that is in any of these states is **pending** (*k_work_is_pending()*) or **busy** (*k_work_busy_get()*).

A handler function can use any kernel API available to threads. However, operations that are potentially blocking (e.g. taking a semaphore) must be used with care, since the workqueue cannot process subsequent work items in its queue until the handler function finishes executing.

The single argument that is passed to a handler function can be ignored if it is not required. If the handler function requires additional information about the work it is to perform, the work item can be embedded in a larger data structure. The handler function can then use the argument value to compute the address of the enclosing data structure with *CONTAINER_OF*, and thereby obtain access to the additional information it needs.

A work item is typically initialized once and then submitted to a specific workqueue whenever work needs to be performed. If an ISR or a thread attempts to submit a work item that is already queued the work item is not affected; the work item remains in its current place in the workqueue's queue, and the work is only performed once.

A handler function is permitted to re-submit its work item argument to the workqueue, since the work item is no longer queued at that time. This allows the handler to execute work in stages, without unduly delaying the processing of other work items in the workqueue's queue.

Important

A pending work item *must not* be altered until the item has been processed by the workqueue thread. This means a work item must not be re-initialized while it is busy. Furthermore, any additional information the work item's handler function needs to perform its work must not be altered until the handler function has finished executing.

Delayable Work An ISR or a thread may need to schedule a work item that is to be processed only after a specified period of time, rather than immediately. This can be done by **scheduling** a **delayable work item** to be submitted to a workqueue at a future time.

A delayable work item contains a standard work item but adds fields that record when and where the item should be submitted.

A delayable work item is initialized and scheduled to a workqueue in a similar manner to a standard work item, although different kernel APIs are used. When the schedule request is made the kernel initiates a timeout mechanism that is triggered after the specified delay has elapsed. Once the timeout occurs the kernel submits the work item to the specified workqueue, where it remains queued until it is processed in the standard manner.

Note that work handler used for delayable still receives a pointer to the underlying non-delayable work structure, which is not publicly accessible from *k_work_delayable*. To get access to an object that contains the delayable work object use this idiom:

```
static void work_handler(struct k_work *work)
{
        struct k_work_delayable *dwork = k_work_delayable_from_work(work);
        struct work_context *ctx = CONTAINER_OF(dwork, struct work_context,
```

(continues on next page)

(continued from previous page)

```
                                        timed_work);
    ...
```

Triggered Work The *k_work_poll_submit()* interface schedules a triggered work item in response to a **poll event** (see *Polling API*), that will call a user-defined function when a monitored resource becomes available or poll signal is raised, or a timeout occurs. In contrast to *k_poll()*, the triggered work does not require a dedicated thread waiting or actively polling for a poll event.

A triggered work item is a standard work item that has the following added properties:

- A pointer to an array of poll events that will trigger work item submissions to the workqueue
- A size of the array containing poll events.

A triggered work item is initialized and submitted to a workqueue in a similar manner to a standard work item, although dedicated kernel APIs are used. When a submit request is made, the kernel begins observing kernel objects specified by the poll events. Once at least one of the observed kernel object's changes state, the work item is submitted to the specified workqueue, where it remains queued until it is processed in the standard manner.

Important

The triggered work item as well as the referenced array of poll events have to be valid and cannot be modified for a complete triggered work item lifecycle, from submission to work item execution or cancellation.

An ISR or a thread may **cancel** a triggered work item it has submitted as long as it is still waiting for a poll event. In such case, the kernel stops waiting for attached poll events and the specified work is not executed. Otherwise the cancellation cannot be performed.

System Workqueue The kernel defines a workqueue known as the *system workqueue*, which is available to any application or kernel code that requires workqueue support. The system workqueue is optional, and only exists if the application makes use of it.

Important

Additional workqueues should only be defined when it is not possible to submit new work items to the system workqueue, since each new workqueue incurs a significant cost in memory footprint. A new workqueue can be justified if it is not possible for its work items to co-exist with existing system workqueue work items without an unacceptable impact; for example, if the new work items perform blocking operations that would delay other system workqueue processing to an unacceptable degree.

How to Use Workqueues

Defining and Controlling a Workqueue A workqueue is defined using a variable of type *k_work_q*. The workqueue is initialized by defining the stack area used by its thread, initializing the *k_work_q*, either zeroing its memory or calling *k_work_queue_init()*, and then calling *k_work_queue_start()*. The stack area must be defined using *K_THREAD_STACK_DEFINE* to ensure it is properly set up in memory.

The following code defines and initializes a workqueue:

```
#define MY_STACK_SIZE 512
#define MY_PRIORITY 5

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);

struct k_work_q my_work_q;

k_work_queue_init(&my_work_q);

k_work_queue_start(&my_work_q, my_stack_area,
                   K_THREAD_STACK_SIZEOF(my_stack_area), MY_PRIORITY,
                   NULL);
```

In addition the queue identity and certain behavior related to thread rescheduling can be controlled by the optional final parameter; see *k_work_queue_start()* for details.

The following API can be used to interact with a workqueue:

- *k_work_queue_drain()* can be used to block the caller until the work queue has no items left. Work items resubmitted from the workqueue thread are accepted while a queue is draining, but work items from any other thread or ISR are rejected. The restriction on submitting more work can be extended past the completion of the drain operation in order to allow the blocking thread to perform additional work while the queue is "plugged". Note that draining a queue has no effect on scheduling or processing delayable items, but if the queue is plugged and the deadline expires the item will silently fail to be submitted.
- *k_work_queue_unplug()* removes any previous block on submission to the queue due to a previous drain operation.

Submitting a Work Item A work item is defined using a variable of type *k_work*. It must be initialized by calling *k_work_init()*, unless it is defined using *K_WORK_DEFINE* in which case initialization is performed at compile-time.

An initialized work item can be submitted to the system workqueue by calling *k_work_submit()*, or to a specified workqueue by calling *k_work_submit_to_queue()*.

The following code demonstrates how an ISR can offload the printing of error messages to the system workqueue. Note that if the ISR attempts to resubmit the work item while it is still queued, the work item is left unchanged and the associated error message will not be printed.

```
struct device_info {
    struct k_work work;
    char name[16]
} my_device;

void my_isr(void *arg)
{
    ...
    if (error detected) {
        k_work_submit(&my_device.work);
    }
    ...
}

void print_error(struct k_work *item)
{
    struct device_info *the_device =
        CONTAINER_OF(item, struct device_info, work);
    printk("Got error on device %s\n", the_device->name);
}
```

(continues on next page)

(continued from previous page)

```
/* initialize name info for a device */
strcpy(my_device.name, "FOO_dev");

/* initialize work item for printing device's error messages */
k_work_init(&my_device.work, print_error);

/* install my_isr() as interrupt handler for the device (not shown) */
...
```

The following API can be used to check the status of or synchronize with the work item:

- *k_work_busy_get()* returns a snapshot of flags indicating work item state. A zero value indicates the work is not scheduled, submitted, being executed, or otherwise still being referenced by the workqueue infrastructure.
- *k_work_is_pending()* is a helper that indicates `true` if and only if the work is scheduled, queued, or running.
- *k_work_flush()* may be invoked from threads to block until the work item has completed. It returns immediately if the work is not pending.
- *k_work_cancel()* attempts to prevent the work item from being executed. This may or may not be successful. This is safe to invoke from ISRs.
- *k_work_cancel_sync()* may be invoked from threads to block until the work completes; it will return immediately if the cancellation was successful or not necessary (the work wasn't submitted or running). This can be used after *k_work_cancel()* is invoked (from an ISR)' to confirm completion of an ISR-initiated cancellation.

Scheduling a Delayable Work Item A delayable work item is defined using a variable of type *k_work_delayable*. It must be initialized by calling *k_work_init_delayable()*.

For delayed work there are two common use cases, depending on whether a deadline should be extended if a new event occurs. An example is collecting data that comes in asynchronously, e.g. characters from a UART associated with a keyboard. There are two APIs that submit work after a delay:

- *k_work_schedule()* (or *k_work_schedule_for_queue()*) schedules work to be executed at a specific time or after a delay. Further attempts to schedule the same item with this API before the delay completes will not change the time at which the item will be submitted to its queue. Use this if the policy is to keep collecting data until a specified delay since the **first** unprocessed data was received;
- *k_work_reschedule()* (or *k_work_reschedule_for_queue()*) unconditionally sets the deadline for the work, replacing any previous incomplete delay and changing the destination queue if necessary. Use this if the policy is to keep collecting data until a specified delay since the **last** unprocessed data was received.

If the work item is not scheduled both APIs behave the same. If *K_NO_WAIT* is specified as the delay the behavior is as if the item was immediately submitted directly to the target queue, without waiting for a minimal timeout (unless *k_work_schedule()* is used and a previous delay has not completed).

Both also have variants that allow control of the queue used for submission.

The helper function *k_work_delayable_from_work()* can be used to get a pointer to the containing *k_work_delayable* from a pointer to *k_work* that is passed to a work handler function.

The following additional API can be used to check the status of or synchronize with the work item:

- *k_work_delayable_busy_get()* is the analog to *k_work_busy_get()* for delayable work.

- *k_work_delayable_is_pending()* is the analog to *k_work_is_pending()* for delayable work.
- *k_work_flush_delayable()* is the analog to *k_work_flush()* for delayable work.
- *k_work_cancel_delayable()* is the analog to *k_work_cancel()* for delayable work; similarly with *k_work_cancel_delayable_sync()*.

Synchronizing with Work Items While the state of both regular and delayable work items can be determined from any context using *k_work_busy_get()* and *k_work_delayable_busy_get()* some use cases require synchronizing with work items after they've been submitted. *k_work_flush()*, *k_work_cancel_sync()*, and *k_work_cancel_delayable_sync()* can be invoked from thread context to wait until the requested state has been reached.

These APIs must be provided with a *k_work_sync* object that has no application-inspectable components but is needed to provide the synchronization objects. These objects should not be allocated on a stack if the code is expected to work on architectures with CONFIG_KERNEL_COHERENCE.

Workqueue Best Practices

Avoid Race Conditions Sometimes the data a work item must process is naturally thread-safe, for example when it's put into a k_queue by some thread and processed in the work thread. More often external synchronization is required to avoid data races: cases where the work thread might inspect or manipulate shared state that's being accessed by another thread or interrupt. Such state might be a flag indicating that work needs to be done, or a shared object that is filled by an ISR or thread and read by the work handler.

For simple flags *Atomic Services* may be sufficient. In other cases spin locks (*k_spinlock*) or thread-aware locks (k_sem, *k_mutex* , ...) may be used to ensure data races don't occur.

If the selected lock mechanism can *sleep* then allowing the work thread to sleep will starve other work queue items, which may need to make progress in order to get the lock released. Work handlers should try to take the lock with its no-wait path. For example:

```
static void work_handler(struct work *work)
{
        struct work_context *parent = CONTAINER_OF(work, struct work_context,
                                                   work_item);

        if (k_mutex_lock(&parent->lock, K_NO_WAIT) != 0) {
                /* NB: Submit will fail if the work item is being cancelled. */
                (void)k_work_submit(work);
                return;
        }

        /* do stuff under lock */
        k_mutex_unlock(&parent->lock);
        /* do stuff without lock */
}
```

Be aware that if the lock is held by a thread with a lower priority than the work queue the resubmission may starve the thread that would release the lock, causing the application to fail. Where the idiom above is required a delayable work item is preferred, and the work should be (re-)scheduled with a non-zero delay to allow the thread holding the lock to make progress.

Note that submitting from the work handler can fail if the work item had been cancelled. Generally this is acceptable, since the cancellation will complete once the handler finishes. If it is not, the code above must take other steps to notify the application that the work could not be performed.

Work items in isolation are self-locking, so you don't need to hold an external lock just to submit or schedule them. Even if you use external state protected by such a lock to prevent further resubmission, it's safe to do the resubmit as long as you're sure that eventually the item will take its lock and check that state to determine whether it should do anything. Where a delayable work item is being rescheduled in its handler due to inability to take the lock some other self-locking state, such as an atomic flag set by the application/driver when the cancel is initiated, would be required to detect the cancellation and avoid the cancelled work item being submitted again after the deadline.

Check Return Values All work API functions return status of the underlying operation, and in many cases it is important to verify that the intended result was obtained.

- Submitting a work item (*k_work_submit_to_queue()*) can fail if the work is being cancelled or the queue is not accepting new items. If this happens the work will not be executed, which could cause a subsystem that is animated by work handler activity to become non-responsive.
- Asynchronous cancellation (*k_work_cancel()* or *k_work_cancel_delayable()*) can complete while the work item is still being run by a handler. Proceeding to manipulate state shared with the work handler will result in data races that can cause failures.

Many race conditions have been present in Zephyr code because the results of an operation were not checked.

There may be good reason to believe that a return value indicating that the operation did not complete as expected is not a problem. In those cases the code should clearly document this, by (1) casting the return value to `void` to indicate that the result is intentionally ignored, and (2) documenting what happens in the unexpected case. For example:

```
/* If this fails, the work handler will check pub->active and
 * exit without transmitting.
 */
(void)k_work_cancel_delayable(&pub->timer);
```

However in such a case the following code must still avoid data races, as it cannot guarantee that the work thread is not accessing work-related state.

Don't Optimize Prematurely The workqueue API is designed to be safe when invoked from multiple threads and interrupts. Attempts to externally inspect a work item's state and make decisions based on the result are likely to create new problems.

So when new work comes in, just submit it. Don't attempt to "optimize" by checking whether the work item is already submitted by inspecting snapshot state with *k_work_is_pending()* or *k_work_busy_get()*, or checking for a non-zero delay from *k_work_delayable_remaining_get()*. Those checks are fragile: a "busy" indication can be obsolete by the time the test is returned, and a "not-busy" indication can also be wrong if work is submitted from multiple contexts, or (for delayable work) if the deadline has completed but the work is still in queued or running state.

A general best practice is to always maintain in shared state some condition that can be checked by the handler to confirm whether there is work to be done. This way you can use the work handler as the standard cleanup path: rather than having to deal with cancellation and cleanup at points where items are submitted, you may be able to have everything done in the work handler itself.

A rare case where you could safely use *k_work_is_pending()* is as a check to avoid invoking *k_work_flush()* or *k_work_cancel_sync()*, if you are *certain* that nothing else might submit the work while you're checking (generally because you're holding a lock that prevents access to state used for submission).

Suggested Uses Use the system workqueue to defer complex interrupt-related processing from an ISR to a shared thread. This allows the interrupt-related processing to be done promptly without compromising the system's ability to respond to subsequent interrupts, and does not require the application to define and manage an additional thread to do the processing.

Configuration Options Related configuration options:

- CONFIG_SYSTEM_WORKQUEUE_PRIORITY
- CONFIG_SYSTEM_WORKQUEUE_NO_YIELD

API Reference

group workqueue_apis

Defines

K_WORK_DELAYABLE_DEFINE(work, work_handler)

Initialize a statically-defined delayable work item.

This macro can be used to initialize a statically-defined delayable work item, prior to its first use. For example,

```
static K_WORK_DELAYABLE_DEFINE(<dwork>, <work_handler>);
```

Note that if the runtime dependencies support initialization with *k_work_init_delayable()* using that will eliminate the initialized object in ROM that is produced by this macro and copied in at system startup.

Parameters

- **work** – Symbol name for delayable work item object
- **work_handler** – Function to invoke each time work item is processed.

K_WORK_USER_DEFINE(work, work_handler)

Initialize a statically-defined user work item.

This macro can be used to initialize a statically-defined user work item, prior to its first use. For example,

```
static K_WORK_USER_DEFINE(<work>, <work_handler>);
```

Parameters

- **work** – Symbol name for work item object
- **work_handler** – Function to invoke each time work item is processed.

K_WORK_DEFINE(work, work_handler)

Initialize a statically-defined work item.

This macro can be used to initialize a statically-defined workqueue work item, prior to its first use. For example,

```
static K_WORK_DEFINE(<work>, <work_handler>);
```

Parameters

- `work` – Symbol name for work item object
- `work_handler` – Function to invoke each time work item is processed.

Typedefs

typedef void (*`k_work_handler_t`)(struct *k_work* *work)

The signature for a work item handler function.

The function will be invoked by the thread animating a work queue.

Param work
the work item that provided the handler.

typedef void (*`k_work_user_handler_t`)(struct k_work_user *work)

Work item handler function type for user work queues.

A work item's handler function is executed by a user workqueue's thread when the work item is processed by the workqueue.

Param work
Address of the work item.

Enums

Values:

enumerator `K_WORK_RUNNING` = *BIT*(K_WORK_RUNNING_BIT)

Flag indicating a work item that is running under a work queue thread.

Accessed via *k_work_busy_get()*. May co-occur with other flags.

enumerator `K_WORK_CANCELING` = *BIT*(K_WORK_CANCELING_BIT)

Flag indicating a work item that is being canceled.

```
Accessed via k_work_busy_get().  May co-occur with other flags.
```

enumerator `K_WORK_QUEUED` = *BIT*(K_WORK_QUEUED_BIT)

Flag indicating a work item that has been submitted to a queue but has not started running.

Accessed via *k_work_busy_get()*. May co-occur with other flags.

enumerator `K_WORK_DELAYED` = *BIT*(K_WORK_DELAYED_BIT)

Flag indicating a delayed work item that is scheduled for submission to a queue.

Accessed via *k_work_busy_get()*. May co-occur with other flags.

enumerator `K_WORK_FLUSHING` = *BIT*(K_WORK_FLUSHING_BIT)

Flag indicating a synced work item that is being flushed.

```
Accessed via k_work_busy_get().  May co-occur with other flags.
```

Functions

void **k_work_init**(struct *k_work* *work, *k_work_handler_t* handler)

Initialize a (non-delayable) work structure.

This must be invoked before submitting a work structure for the first time. It need not be invoked again on the same work structure. It can be re-invoked to change the associated handler, but this must be done when the work item is idle.

Function properties (list may not be complete)

isr-ok

Parameters

- **work** – the work structure to be initialized.
- **handler** – the handler to be invoked by the work item.

int **k_work_busy_get**(const struct *k_work* *work)

Busy state flags from the work item.

A zero return value indicates the work item appears to be idle.

Function properties (list may not be complete)

isr-ok

Note

This is a live snapshot of state, which may change before the result is checked. Use locks where appropriate.

Parameters

- **work** – pointer to the work item.

Returns

a mask of flags K_WORK_DELAYED, K_WORK_QUEUED, K_WORK_RUNNING, K_WORK_CANCELING, and K_WORK_FLUSHING.

static inline bool **k_work_is_pending**(const struct *k_work* *work)

Test whether a work item is currently pending.

Wrapper to determine whether a work item is in a non-idle dstate.

Function properties (list may not be complete)

isr-ok

Note

This is a live snapshot of state, which may change before the result is checked. Use locks where appropriate.

Parameters

- **work** – pointer to the work item.

Returns
true if and only if *k_work_busy_get()* returns a non-zero value.

int **k_work_submit_to_queue**(struct *k_work_q* *queue, struct *k_work* *work)
Submit a work item to a queue.

Function properties (list may not be complete)
isr-ok

Parameters

- **queue** – pointer to the work queue on which the item should run. If NULL the queue from the most recent submission will be used.
- **work** – pointer to the work item.

Return values

- **0** – if work was already submitted to a queue
- **1** – if work was not submitted and has been queued to queue
- **2** – if work was running and has been queued to the queue that was running it
- **-EBUSY** –
  - if work submission was rejected because the work item is cancelling; or
  - queue is draining; or
  - queue is plugged.
- **-EINVAL** – if queue is null and the work item has never been run.
- **-ENODEV** – if queue has not been started.

int **k_work_submit**(struct *k_work* *work)
Submit a work item to the system queue.

Function properties (list may not be complete)
isr-ok

Parameters

- **work** – pointer to the work item.

Returns
as with *k_work_submit_to_queue()*.

bool **k_work_flush**(struct *k_work* *work, struct *k_work_sync* *sync)
Wait for last-submitted instance to complete.

Resubmissions may occur while waiting, including chained submissions (from within the handler).

Note

Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

Note

Behavior is undefined if this function is invoked on `work` from a work queue running `work`.

Parameters

- `work` – pointer to the work item.
- `sync` – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

Return values

- `true` – if call had to wait for completion
- `false` – if work was already idle

int **k_work_cancel**(struct *k_work* *work)

Cancel a work item.

This attempts to prevent a pending (non-delayable) work item from being processed by removing it from the work queue. If the item is being processed, the work item will continue to be processed, but resubmissions are rejected until cancellation completes.

If this returns zero cancellation is complete, otherwise something (probably a work queue thread) is still referencing the item.

See also *k_work_cancel_sync()*.

Function properties (list may not be complete)

isr-ok

Parameters

- `work` – pointer to the work item.

Returns

the *k_work_busy_get()* status indicating the state of the item after all cancellation steps performed by this call are completed.

bool **k_work_cancel_sync**(struct *k_work* *work, struct *k_work_sync* *sync)

Cancel a work item and wait for it to complete.

Same as *k_work_cancel()* but does not return until cancellation is complete. This can be invoked by a thread after *k_work_cancel()* to synchronize with a previous cancellation.

On return the work structure will be idle unless something submits it after the cancellation was complete.

Note

Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

Note

Behavior is undefined if this function is invoked on `work` from a work queue running `work`.

Parameters

- `work` – pointer to the work item.
- `sync` – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

Return values

- `true` – if work was pending (call had to wait for cancellation of a running handler to complete, or scheduled or submitted operations were cancelled);
- `false` – otherwise

void **k_work_queue_init**(struct *k_work_q* *queue)

Initialize a work queue structure.

This must be invoked before starting a work queue structure for the first time. It need not be invoked again on the same work queue structure.

Function properties (list may not be complete)

isr-ok

Parameters

- `queue` – the queue structure to be initialized.

void **k_work_queue_start**(struct *k_work_q* *queue, k_thread_stack_t *stack, size_t stack_size, int prio, const struct *k_work_queue_config* *cfg)

Initialize a work queue.

This configures the work queue thread and starts it running. The function should not be re-invoked on a queue.

Parameters

- `queue` – pointer to the queue structure. It must be initialized in zeroed/bss memory or with *k_work_queue_init* before use.
- `stack` – pointer to the work thread stack area.
- `stack_size` – size of the work thread stack area, in bytes.
- `prio` – initial thread priority
- `cfg` – optional additional configuration parameters. Pass `NULL` if not required, to use the defaults documented in *k_work_queue_config*.

static inline k_tid_t **k_work_queue_thread_get**(struct *k_work_q* *queue)

Access the thread that animates a work queue.

This is necessary to grant a work queue thread access to things the work items it will process are expected to use.

Parameters

- `queue` – pointer to the queue structure.

Returns
the thread associated with the work queue.

int `k_work_queue_drain`(struct *k_work_q* *queue, bool plug)

Wait until the work queue has drained, optionally plugging it.

This blocks submission to the work queue except when coming from queue thread, and blocks the caller until no more work items are available in the queue.

If `plug` is true then submission will continue to be blocked after the drain operation completes until *k_work_queue_unplug()* is invoked.

Note that work items that are delayed are not yet associated with their work queue. They must be cancelled externally if a goal is to ensure the work queue remains empty. The `plug` feature can be used to prevent delayed items from being submitted after the drain completes.

Parameters

- `queue` – pointer to the queue structure.
- `plug` – if true the work queue will continue to block new submissions after all items have drained.

Return values

- `1` – if call had to wait for the drain to complete
- `0` – if call did not have to wait
- `negative` – if wait was interrupted or failed

int `k_work_queue_unplug`(struct *k_work_q* *queue)

Release a work queue to accept new submissions.

This releases the block on new submissions placed when *k_work_queue_drain()* is invoked with the `plug` option enabled. If this is invoked before the drain completes new items may be submitted as soon as the drain completes.

Function properties (list may not be complete)
isr-ok

Parameters

- `queue` – pointer to the queue structure.

Return values

- `0` – if successfully unplugged
- `-EALREADY` – if the work queue was not plugged.

void `k_work_init_delayable`(struct *k_work_delayable* *dwork, *k_work_handler_t* handler)

Initialize a delayable work structure.

This must be invoked before scheduling a delayable work structure for the first time. It need not be invoked again on the same work structure. It can be re-invoked to change the associated handler, but this must be done when the work item is idle.

Function properties (list may not be complete)
isr-ok

Parameters

- `dwork` – the delayable work structure to be initialized.
- `handler` – the handler to be invoked by the work item.

static inline struct *k_work_delayable* *`k_work_delayable_from_work`(struct *k_work* *work)

Get the parent delayable work structure from a work pointer.

This function is necessary when a `k_work_handler_t` function is passed to *k_work_schedule_for_queue()* and the handler needs to access data from the container of the containing *`k_work_delayable`*.

Parameters

- `work` – Address passed to the work handler

Returns
Address of the containing *`k_work_delayable`* structure.

int `k_work_delayable_busy_get`(const struct *k_work_delayable* *dwork)

Busy state flags from the delayable work item.

Function properties (list may not be complete)
isr-ok

Note

This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters

- `dwork` – pointer to the delayable work item.

Returns
a mask of flags K_WORK_DELAYED, K_WORK_QUEUED, K_WORK_RUNNING, K_WORK_CANCELING, and K_WORK_FLUSHING. A zero return value indicates the work item appears to be idle.

static inline bool `k_work_delayable_is_pending`(const struct *k_work_delayable* *dwork)

Test whether a delayed work item is currently pending.

Wrapper to determine whether a delayed work item is in a non-idle state.

Function properties (list may not be complete)
isr-ok

Note

This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters

- **dwork** – pointer to the delayable work item.

Returns
true if and only if *k_work_delayable_busy_get()* returns a non-zero value.

static inline *k_ticks_t* **k_work_delayable_expires_get**(const struct *k_work_delayable* *dwork)

Get the absolute tick count at which a scheduled delayable work will be submitted.

Function properties (list may not be complete)
isr-ok

Note

This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters

- **dwork** – pointer to the delayable work item.

Returns
the tick count when the timer that will schedule the work item will expire, or the current tick count if the work is not scheduled.

static inline *k_ticks_t* **k_work_delayable_remaining_get**(const struct *k_work_delayable* *dwork)

Get the number of ticks until a scheduled delayable work will be submitted.

Function properties (list may not be complete)
isr-ok

Note

This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters

- **dwork** – pointer to the delayable work item.

Returns
the number of ticks until the timer that will schedule the work item will expire, or zero if the item is not scheduled.

int **k_work_schedule_for_queue**(struct *k_work_q* *queue, struct *k_work_delayable* *dwork, *k_timeout_t* delay)

Submit an idle work item to a queue after a delay.

Unlike *k_work_reschedule_for_queue()* this is a no-op if the work item is already scheduled or submitted, even if `delay` is `K_NO_WAIT`.

Function properties (list may not be complete)
isr-ok

Parameters

- **queue** – the queue on which the work item should be submitted after the delay.
- **dwork** – pointer to the delayable work item.
- **delay** – the time to wait before submitting the work item. If K_NO_WAIT and the work is not pending this is equivalent to *k_work_submit_to_queue()*.

Return values

- **0** – if work was already scheduled or submitted.
- **1** – if work has been scheduled.
- **2** – if delay is K_NO_WAIT and work was running and has been queued to the queue that was running it.
- **-EBUSY** – if delay is K_NO_WAIT and *k_work_submit_to_queue()* fails with this code.
- **-EINVAL** – if delay is K_NO_WAIT and *k_work_submit_to_queue()* fails with this code.
- **-ENODEV** – if delay is K_NO_WAIT and *k_work_submit_to_queue()* fails with this code.

int **k_work_schedule**(struct *k_work_delayable* *dwork, *k_timeout_t* delay)

Submit an idle work item to the system work queue after a delay.

This is a thin wrapper around *k_work_schedule_for_queue()*, with all the API characteristics of that function.

Parameters

- **dwork** – pointer to the delayable work item.
- **delay** – the time to wait before submitting the work item. If K_NO_WAIT this is equivalent to *k_work_submit_to_queue()*.

Returns

as with *k_work_schedule_for_queue()*.

int **k_work_reschedule_for_queue**(struct *k_work_q* *queue, struct *k_work_delayable* *dwork, *k_timeout_t* delay)

Reschedule a work item to a queue after a delay.

Unlike *k_work_schedule_for_queue()* this function can change the deadline of a scheduled work item, and will schedule a work item that is in any state (e.g. is idle, submitted, or running). This function does not affect ("unsubmit") a work item that has been submitted to a queue.

Function properties (list may not be complete)

isr-ok

Note

If delay is K_NO_WAIT ("no delay") the return values are as with *k_work_submit_to_queue()*.

Parameters

- **queue** – the queue on which the work item should be submitted after the delay.
- **dwork** – pointer to the delayable work item.
- **delay** – the time to wait before submitting the work item. If K_NO_WAIT this is equivalent to *k_work_submit_to_queue()* after canceling any previous scheduled submission.

Return values

- **0** – if delay is K_NO_WAIT and work was already on a queue
- **1** – if
  - delay is K_NO_WAIT and work was not submitted but has now been queued to queue; or
  - delay not K_NO_WAIT and work has been scheduled
- **2** – if delay is K_NO_WAIT and work was running and has been queued to the queue that was running it
- **-EBUSY** – if delay is K_NO_WAIT and *k_work_submit_to_queue()* fails with this code.
- **-EINVAL** – if delay is K_NO_WAIT and *k_work_submit_to_queue()* fails with this code.
- **-ENODEV** – if delay is K_NO_WAIT and *k_work_submit_to_queue()* fails with this code.

int **k_work_reschedule**(struct *k_work_delayable* *dwork, *k_timeout_t* delay)

Reschedule a work item to the system work queue after a delay.

This is a thin wrapper around *k_work_reschedule_for_queue()*, with all the API characteristics of that function.

Parameters

- **dwork** – pointer to the delayable work item.
- **delay** – the time to wait before submitting the work item.

Returns

as with *k_work_reschedule_for_queue()*.

bool **k_work_flush_delayable**(struct *k_work_delayable* *dwork, struct *k_work_sync* *sync)

Flush delayable work.

If the work is scheduled, it is immediately submitted. Then the caller blocks until the work completes, as with *k_work_flush()*.

Note

Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

Note

Behavior is undefined if this function is invoked on dwork from a work queue running dwork.

Parameters

- `dwork` – pointer to the delayable work item.
- `sync` – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

Return values

- `true` – if call had to wait for completion
- `false` – if work was already idle

int **k_work_cancel_delayable**(struct *k_work_delayable* *dwork)

Cancel delayable work.

Similar to *k_work_cancel()* but for delayable work. If the work is scheduled or submitted it is canceled. This function does not wait for the cancellation to complete.

Function properties (list may not be complete)

isr-ok

Note

The work may still be running when this returns. Use *k_work_flush_delayable()* or *k_work_cancel_delayable_sync()* to ensure it is not running.

Note

Canceling delayable work does not prevent rescheduling it. It does prevent submitting it until the cancellation completes.

Parameters

- `dwork` – pointer to the delayable work item.

Returns

the *k_work_delayable_busy_get()* status indicating the state of the item after all cancellation steps performed by this call are completed.

bool **k_work_cancel_delayable_sync**(struct *k_work_delayable* *dwork, struct *k_work_sync* *sync)

Cancel delayable work and wait.

Like *k_work_cancel_delayable()* but waits until the work becomes idle.

Note

Canceling delayable work does not prevent rescheduling it. It does prevent submitting it until the cancellation completes.

Note

Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

Note

Behavior is undefined if this function is invoked on `dwork` from a work queue running `dwork`.

Parameters

- `dwork` – pointer to the delayable work item.
- `sync` – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

Return values

- `true` – if work was not idle (call had to wait for cancellation of a running handler to complete, or scheduled or submitted operations were cancelled);
- `false` – otherwise

static inline void **k_work_user_init**(struct k_work_user *work, *k_work_user_handler_t* handler)

Initialize a userspace work item.

This routine initializes a user workqueue work item, prior to its first use.

Parameters

- `work` – Address of work item.
- `handler` – Function to invoke each time work item is processed.

static inline bool **k_work_user_is_pending**(struct k_work_user *work)

Check if a userspace work item is pending.

This routine indicates if user work item *work* is pending in a workqueue's queue.

Function properties (list may not be complete)

isr-ok

Note

Checking if the work is pending gives no guarantee that the work will still be pending when this information is used. It is up to the caller to make sure that this information is used in a safe manner.

Parameters

- `work` – Address of work item.

Returns
true if work item is pending, or false if it is not pending.

static inline int **k_work_user_submit_to_queue**(struct k_work_user_q *work_q, struct k_work_user *work)

Submit a work item to a user mode workqueue.

Submits a work item to a workqueue that runs in user mode. A temporary memory allocation is made from the caller's resource pool which is freed once the worker thread consumes the *k_work* item. The workqueue thread must have memory access to the *k_work* item being submitted. The caller must have permission granted on the work_q parameter's queue object.

Function properties (list may not be complete)
isr-ok

Parameters

- **work_q** – Address of workqueue.
- **work** – Address of work item.

Return values

- **-EBUSY** – if the work item was already in some workqueue
- **-ENOMEM** – if no memory for thread resource pool allocation
- **0** – Success

void **k_work_user_queue_start**(struct k_work_user_q *work_q, k_thread_stack_t *stack, size_t stack_size, int prio, const char *name)

Start a workqueue in user mode.

This works identically to *k_work_queue_start()* except it is callable from user mode, and the worker thread created will run in user mode. The caller must have permissions granted on both the work_q parameter's thread and queue objects, and the same restrictions on priority apply as *k_thread_create()*.

Parameters

- **work_q** – Address of workqueue.
- **stack** – Pointer to work queue thread's stack space, as defined by *K_THREAD_STACK_DEFINE()*
- **stack_size** – Size of the work queue thread's stack (in bytes), which should either be the same constant passed to *K_THREAD_STACK_DEFINE()* or the value of *K_THREAD_STACK_SIZEOF()*.
- **prio** – Priority of the work queue's thread.
- **name** – optional thread name. If not null a copy is made into the thread's name buffer.

static inline k_tid_t **k_work_user_queue_thread_get**(struct k_work_user_q *work_q)

Access the user mode thread that animates a work queue.

This is necessary to grant a user mode work queue thread access to things the work items it will process are expected to use.

Parameters

- **work_q** – pointer to the user mode queue structure.

Returns
the user mode thread associated with the work queue.

void **k_work_poll_init**(struct k_work_poll *work, *k_work_handler_t* handler)

Initialize a triggered work item.

This routine initializes a workqueue triggered work item, prior to its first use.

Parameters

- **work** – Address of triggered work item.
- **handler** – Function to invoke each time work item is processed.

int **k_work_poll_submit_to_queue**(struct *k_work_q* *work_q, struct k_work_poll *work, struct *k_poll_event* *events, int num_events, *k_timeout_t* timeout)

Submit a triggered work item.

This routine schedules work item *work* to be processed by workqueue *work_q* when one of the given *events* is signaled. The routine initiates internal poller for the work item and then returns to the caller. Only when one of the watched events happen the work item is actually submitted to the workqueue and becomes pending.

Submitting a previously submitted triggered work item that is still waiting for the event cancels the existing submission and reschedules it the using the new event list. Note that this behavior is inherently subject to race conditions with the pre-existing triggered work item and work queue, so care must be taken to synchronize such resubmissions externally.

Function properties (list may not be complete)
isr-ok

Warning

Provided array of events as well as a triggered work item must be placed in persistent memory (valid until work handler execution or work cancellation) and cannot be modified after submission.

Parameters

- **work_q** – Address of workqueue.
- **work** – Address of delayed work item.
- **events** – An array of events which trigger the work.
- **num_events** – The number of events in the array.
- **timeout** – Timeout after which the work will be scheduled for execution even if not triggered.

Return values

- **0** – Work item started watching for events.
- **-EINVAL** – Work item is being processed or has completed its work.
- **-EADDRINUSE** – Work item is pending on a different workqueue.

int **k_work_poll_submit**(struct k_work_poll *work, struct *k_poll_event* *events, int num_events, *k_timeout_t* timeout)

Submit a triggered work item to the system workqueue.

This routine schedules work item *work* to be processed by system workqueue when one of the given *events* is signaled. The routine initiates internal poller for the work item and then returns to the caller. Only when one of the watched events happen the work item is actually submitted to the workqueue and becomes pending.

Submitting a previously submitted triggered work item that is still waiting for the event cancels the existing submission and reschedules it the using the new event list. Note that this behavior is inherently subject to race conditions with the pre-existing triggered work item and work queue, so care must be taken to synchronize such resubmissions externally.

Function properties (list may not be complete)

isr-ok

Warning

Provided array of events as well as a triggered work item must not be modified until the item has been processed by the workqueue.

Parameters

- `work` – Address of delayed work item.
- `events` – An array of events which trigger the work.
- `num_events` – The number of events in the array.
- `timeout` – Timeout after which the work will be scheduled for execution even if not triggered.

Return values

- `0` – Work item started watching for events.
- `-EINVAL` – Work item is being processed or has completed its work.
- `-EADDRINUSE` – Work item is pending on a different workqueue.

int `k_work_poll_cancel`(struct k_work_poll *work)

Cancel a triggered work item.

This routine cancels the submission of triggered work item *work*. A triggered work item can only be canceled if no event triggered work submission.

Function properties (list may not be complete)

isr-ok

Parameters

- `work` – Address of delayed work item.

Return values

- `0` – Work item canceled.
- `-EINVAL` – Work item is being processed or has completed its work.

struct `k_work`

#include <*kernel.h*> A structure used to submit work.

struct `k_work_delayable`

#include <*kernel.h*> A structure used to submit work after a delay.

struct `k_work_sync`

#include <*kernel.h*> A structure holding internal state for a pending synchronous operation on a work item or queue.

Instances of this type are provided by the caller for invocation of *k_work_flush()*, *k_work_cancel_sync()* and sibling flush and cancel APIs. A referenced object must persist until the call returns, and be accessible from both the caller thread and the work queue thread.

Note

If CONFIG_KERNEL_COHERENCE is enabled the object must be allocated in coherent memory; see *arch_mem_coherent()*. The stack on these architectures is generally not coherent. be stack-allocated. Violations are detected by runtime assertion.

struct `k_work_queue_config`

#include <*kernel.h*> A structure holding optional configuration items for a work queue.

This structure, and values it references, are not retained by *k_work_queue_start()*.

Public Members

const char *`name`

The name to be given to the work queue thread.

If left null the thread will not have a name.

bool `no_yield`

Control whether the work queue thread should yield between items.

Yielding between items helps guarantee the work queue thread does not starve other threads, including cooperative ones released by a work item. This is the default behavior.

Set this to `true` to prevent the work queue thread from yielding between items. This may be appropriate when a sequence of items should complete without yielding control.

bool `essential`

Control whether the work queue thread should be marked as essential thread.

struct `k_work_q`

#include <*kernel.h*> A structure used to hold work until it can be processed.

Operation without Threads

Thread support is not necessary in some applications:

- Bootloaders
- Simple event-driven applications
- Examples intended to demonstrate core functionality

Thread support can be disabled by setting `CONFIG_MULTITHREADING` to `n`. Since this configuration has a significant impact on Zephyr's functionality and testing of it has been limited, there are conditions on what can be expected to work in this configuration.

What Can be Expected to Work These core capabilities shall function correctly when `CONFIG_MULTITHREADING` is disabled:

- The *build system*
- The ability to boot the application to `main()`
- *Interrupt management*
- The system clock including *`k_uptime_get()`*
- Timers, i.e. `k_timer()`
- Non-sleeping delays e.g. *`k_busy_wait()`*.
- Sleeping *`k_cpu_idle()`*.
- Pre `main()` drivers and subsystems initialization e.g. `SYS_INIT`.
- *Memory Management*
- Specifically identified drivers in certain subsystems, listed below.

The expectations above affect selection of other features; for example `CONFIG_SYS_CLOCK_EXISTS` cannot be set to `n`.

What Cannot be Expected to Work Functionality that will not work with `CONFIG_MULTITHREADING` includes majority of the kernel API:

- *Threads*
- *Scheduling*
- *Workqueue Threads*
- *Polling API*
- *Semaphores*
- *Mutexes*
- *Condition Variables*
- *Data Passing*

Subsystem Behavior Without Thread Support The sections below list driver and functional subsystems that are expected to work to some degree when `CONFIG_MULTITHREADING` is disabled. Subsystems that are not listed here should not be expected to work.

Some existing drivers within the listed subsystems do not work when threading is disabled, but are within scope based on their subsystem, or may be sufficiently isolated that supporting them on a particular platform is low-impact. Enhancements to add support to existing capabilities that were not originally implemented to work with threads disabled will be considered.

Flash The *Flash* is expected to work for all SoC flash peripheral drivers. Bus-accessed devices like serial memories may not be supported.

List/table of supported drivers to go here

GPIO The *General-Purpose Input/Output (GPIO)* is expected to work for all SoC GPIO peripheral drivers. Bus-accessed devices like GPIO extenders may not be supported.

List/table of supported drivers to go here

UART A subset of the *Universal Asynchronous Receiver-Transmitter (UART)* is expected to work for all SoC UART peripheral drivers.

- Applications that select `CONFIG_UART_INTERRUPT_DRIVEN` may work, depending on driver implementation.
- Applications that select `CONFIG_UART_ASYNC_API` may work, depending on driver implementation.
- Applications that do not select either `CONFIG_UART_ASYNC_API` or `CONFIG_UART_INTERRUPT_DRIVEN` are expected to work.

List/table of supported drivers to go here, including which API options are supported

Interrupts

An *interrupt service routine* (ISR) is a function that executes asynchronously in response to a hardware or software interrupt. An ISR normally preempts the execution of the current thread, allowing the response to occur with very low overhead. Thread execution resumes only once all ISR work has been completed.

- *Concepts*
  - *Multi-level Interrupt Handling*
  - *Preventing Interruptions*
  - *Offloading ISR Work*

  - *Defining a regular ISR*
  - *Defining a 'direct' ISR*
  - *Sharing an interrupt line*
  - *Dynamically disconnecting an ISR*
  - *Implementation Details*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of ISRs can be defined (limited only by available RAM), subject to the constraints imposed by underlying hardware.

An ISR has the following key properties:

- An **interrupt request (IRQ) signal** that triggers the ISR.
- A **priority level** associated with the IRQ.
- An **interrupt service routine** that is invoked to handle the interrupt.
- An **argument value** that is passed to that function.

An IDT (Interrupt Descriptor Table) or a vector table is used to associate a given interrupt source with a given ISR. Only a single ISR can be associated with a specific IRQ at any given time.

Multiple ISRs can utilize the same function to process interrupts, allowing a single function to service a device that generates multiple types of interrupts or to service multiple devices (usually of the same type). The argument value passed to an ISR's function allows the function to determine which interrupt has been signaled.

The kernel provides a default ISR for all unused IDT entries. This ISR generates a fatal system error if an unexpected interrupt is signaled.

The kernel supports **interrupt nesting**. This allows an ISR to be preempted in mid-execution if a higher priority interrupt is signaled. The lower priority ISR resumes execution once the higher priority ISR has completed its processing.

An ISR executes in the kernel's **interrupt context**. This context has its own dedicated stack area (or, on some architectures, stack areas). The size of the interrupt context stack must be capable of handling the execution of multiple concurrent ISRs if interrupt nesting support is enabled.

Important

Many kernel APIs can be used only by threads, and not by ISRs. In cases where a routine may be invoked by both threads and ISRs the kernel provides the *k_is_in_isr()* API to allow the routine to alter its behavior depending on whether it is executing as part of a thread or as part of an ISR.

Multi-level Interrupt Handling A hardware platform can support more interrupt lines than natively-provided through the use of one or more nested interrupt controllers. Sources of hardware interrupts are combined into one line that is then routed to the parent controller.

If nested interrupt controllers are supported, `CONFIG_MULTI_LEVEL_INTERRUPTS` should be enabled, and `CONFIG_2ND_LEVEL_INTERRUPTS` and `CONFIG_3RD_LEVEL_INTERRUPTS` configured as well, based on the hardware architecture.

A unique 32-bit interrupt number is assigned with information embedded in it to select and invoke the correct Interrupt Service Routine (ISR). Each interrupt level is given a byte within this 32-bit number, providing support for up to four interrupt levels using this arch, as illustrated and explained below:

```
          9             2   0
    - - - - - - - - - - - - -          (LEVEL 1)
  5       |         A   |
- - - - - - -         - - - - - - -    (LEVEL 2)
  |   C                       B
- - - - - - -                          (LEVEL 3)
        D
```

There are three interrupt levels shown here.

- '-' means interrupt line and is numbered from 0 (right most).

- LEVEL 1 has 12 interrupt lines, with two lines (2 and 9) connected to nested controllers and one device 'A' on line 4.
- One of the LEVEL 2 controllers has interrupt line 5 connected to a LEVEL 3 nested controller and one device 'C' on line 3.
- The other LEVEL 2 controller has no nested controllers but has one device 'B' on line 2.
- The LEVEL 3 controller has one device 'D' on line 2.

Here's how unique interrupt numbers are generated for each hardware interrupt. Let's consider four interrupts shown above as A, B, C, and D:

```
A -> 0x00000004
B -> 0x00000302
C -> 0x00000409
D -> 0x00030609
```

Note

The bit positions for LEVEL 2 and onward are offset by 1, as 0 means that interrupt number is not present for that level. For our example, the LEVEL 3 controller has device D on line 2, connected to the LEVEL 2 controller's line 5, that is connected to the LEVEL 1 controller's line 9 (2 -> 5 -> 9). Because of the encoding offset for LEVEL 2 and onward, device D is given the number 0x00030609.

Preventing Interruptions In certain situations it may be necessary for the current thread to prevent ISRs from executing while it is performing time-sensitive or critical section operations.

A thread may temporarily prevent all IRQ handling in the system using an **IRQ lock**. This lock can be applied even when it is already in effect, so routines can use it without having to know if it is already in effect. The thread must unlock its IRQ lock the same number of times it was locked before interrupts can be once again processed by the kernel while the thread is running.

Important

The IRQ lock is thread-specific. If thread A locks out interrupts then performs an operation that puts itself to sleep (e.g. sleeping for N milliseconds), the thread's IRQ lock no longer applies once thread A is swapped out and the next ready thread B starts to run.

This means that interrupts can be processed while thread B is running unless thread B has also locked out interrupts using its own IRQ lock. (Whether interrupts can be processed while the kernel is switching between two threads that are using the IRQ lock is architecture-specific.)

When thread A eventually becomes the current thread once again, the kernel re-establishes thread A's IRQ lock. This ensures thread A won't be interrupted until it has explicitly unlocked its IRQ lock.

If thread A does not sleep but does make a higher-priority thread B ready, the IRQ lock will inhibit any preemption that would otherwise occur. Thread B will not run until the next *reschedule point* reached after releasing the IRQ lock.

Alternatively, a thread may temporarily **disable** a specified IRQ so its associated ISR does not execute when the IRQ is signaled. The IRQ must be subsequently **enabled** to permit the ISR to execute.

Important

Disabling an IRQ prevents *all* threads in the system from being preempted by the associated ISR, not just the thread that disabled the IRQ.

Zero Latency Interrupts Preventing interruptions by applying an IRQ lock may increase the observed interrupt latency. A high interrupt latency, however, may not be acceptable for certain low-latency use-cases.

The kernel addresses such use-cases by allowing interrupts with critical latency constraints to execute at a priority level that cannot be blocked by interrupt locking. These interrupts are defined as *zero-latency interrupts*. The support for zero-latency interrupts requires `CONFIG_ZERO_LATENCY_IRQS` to be enabled. In addition to that, the flag `IRQ_ZERO_LATENCY` must be passed to *`IRQ_CONNECT`* or *`IRQ_DIRECT_CONNECT`* macros to configure the particular interrupt with zero latency.

Zero-latency interrupts are expected to be used to manage hardware events directly, and not to interoperate with the kernel code at all. They should treat all kernel APIs as undefined behavior (i.e. an application that uses the APIs inside a zero-latency interrupt context is responsible for directly verifying correct behavior). Zero-latency interrupts may not modify any data inspected by kernel APIs invoked from normal Zephyr contexts and shall not generate exceptions that need to be handled synchronously (e.g. kernel panic).

Important

Zero-latency interrupts are supported on an architecture-specific basis. The feature is currently implemented in the ARM Cortex-M architecture variant.

Offloading ISR Work An ISR should execute quickly to ensure predictable system operation. If time consuming processing is required the ISR should offload some or all processing to a thread, thereby restoring the kernel's ability to respond to other interrupts.

The kernel supports several mechanisms for offloading interrupt-related processing to a thread.

- An ISR can signal a helper thread to do interrupt-related processing using a kernel object, such as a FIFO, LIFO, or semaphore.
- An ISR can instruct the system workqueue thread to execute a work item. (See *Workqueue Threads*.)

When an ISR offloads work to a thread, there is typically a single context switch to that thread when the ISR completes, allowing interrupt-related processing to continue almost immediately. However, depending on the priority of the thread handling the offload, it is possible that the currently executing cooperative thread or other higher-priority threads may execute before the thread handling the offload is scheduled.

Sharing interrupt lines In the case of some hardware platforms, the same interrupt lines may be used by different IPs. For example, interrupt 17 may be used by a DMA controller to signal that a data transfer has been completed or by a DAI controller to signal that the transfer FIFO has reached its watermark. To make this work, one would have to either employ some special logic or find a workaround (for example, using the shared_irq interrupt controller), which doesn't scale very well.

To solve this problem, one may use shared interrupts, which can be enabled using `CONFIG_SHARED_INTERRUPTS`. Whenever an attempt to register a second ISR/argument pair on the same interrupt line is made (using *`IRQ_CONNECT`* or *`irq_connect_dynamic()`*), the interrupt line

will become shared, meaning the two ISR/argument pairs (previous one and the one that has just been registered) will be invoked each time the interrupt is triggered. The entities that make use of an interrupt line in the shared interrupt context are known as clients. The maximum number of allowed clients for an interrupt is controlled by CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS.

Interrupt sharing is transparent to the user. As such, the user may register interrupts using *IRQ_CONNECT* and *irq_connect_dynamic()* as they normally would. The interrupt sharing is taken care of behind the scenes.

Enabling the shared interrupt support and dynamic interrupt support will allow users to dynamically disconnect ISRs using *irq_disconnect_dynamic()*. After an ISR is disconnected, whenever the interrupt line for which it was register gets triggered, the ISR will no longer get invoked.

Please note that enabling CONFIG_SHARED_INTERRUPTS will result in a non-negligible increase in the binary size. Use with caution.

Implementation

Defining a regular ISR An ISR is defined at runtime by calling *IRQ_CONNECT*. It must then be enabled by calling *irq_enable()*.

Important

IRQ_CONNECT() is not a C function and does some inline assembly magic behind the scenes. All its arguments must be known at build time. Drivers that have multiple instances may need to define per-instance config functions to configure each instance of the interrupt.

The following code defines and enables an ISR.

```
#define MY_DEV_IRQ  24       /* device uses IRQ 24 */
#define MY_DEV_PRIO  2       /* device uses interrupt priority 2 */
/* argument passed to my_isr(), in this case a pointer to the device */
#define MY_ISR_ARG  DEVICE_GET(my_device)
#define MY_IRQ_FLAGS 0       /* IRQ flags */

void my_isr(void *arg)
{
   ... /* ISR code */
}

void my_isr_installer(void)
{
   ...
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG, MY_IRQ_FLAGS);
   irq_enable(MY_DEV_IRQ);
   ...
}
```

Since the *IRQ_CONNECT* macro requires that all its parameters be known at build time, in some cases this may not be acceptable. It is also possible to install interrupts at runtime with *irq_connect_dynamic()*. It is used in exactly the same way as *IRQ_CONNECT*:

```
void my_isr_installer(void)
{
   ...
   irq_connect_dynamic(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG,
                       MY_IRQ_FLAGS);
   irq_enable(MY_DEV_IRQ);
```

(continues on next page)

(continued from previous page)

```
   ...
}
```

Dynamic interrupts require the CONFIG_DYNAMIC_INTERRUPTS option to be enabled. Removing or re-configuring a dynamic interrupt is currently unsupported.

Defining a 'direct' ISR Regular Zephyr interrupts introduce some overhead which may be unacceptable for some low-latency use-cases. Specifically:

- The argument to the ISR is retrieved and passed to the ISR
- If power management is enabled and the system was idle, all the hardware will be resumed from low-power state before the ISR is executed, which can be very time-consuming
- Although some architectures will do this in hardware, other architectures need to switch to the interrupt stack in code
- After the interrupt is serviced, the OS then performs some logic to potentially make a scheduling decision.

Zephyr supports so-called 'direct' interrupts, which are installed via *IRQ_DIRECT_CONNECT*. These direct interrupts have some special implementation requirements and a reduced feature set; see the definition of *IRQ_DIRECT_CONNECT* for details.

The following code demonstrates a direct ISR:

```
#define MY_DEV_IRQ  24       /* device uses IRQ 24 */
#define MY_DEV_PRIO  2       /* device uses interrupt priority 2 */
/* argument passed to my_isr(), in this case a pointer to the device */
#define MY_IRQ_FLAGS 0       /* IRQ flags */

ISR_DIRECT_DECLARE(my_isr)
{
   do_stuff();
   ISR_DIRECT_PM(); /* PM done after servicing interrupt for best latency */
   return 1; /* We should check if scheduling decision should be made */
}

void my_isr_installer(void)
{
   ...
   IRQ_DIRECT_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_IRQ_FLAGS);
   irq_enable(MY_DEV_IRQ);
   ...
}
```

Installation of dynamic direct interrupts is supported on an architecture-specific basis. (The feature is currently implemented in ARM Cortex-M architecture variant. Dynamic direct interrupts feature is exposed to the user via an ARM-only API.)

Sharing an interrupt line The following code defines two ISRs using the same interrupt number.

```
#define MY_DEV_IRQ 24              /* device uses INTID 24 */
#define MY_DEV_IRQ_PRIO 2          /* device uses interrupt priority 2 */
/*  this argument may be anything */
#define MY_FST_ISR_ARG INT_TO_POINTER(1)
/*  this argument may be anything */
#define MY_SND_ISR_ARG INT_TO_POINTER(2)
#define MY_IRQ_FLAGS 0             /* IRQ flags */
```

(continues on next page)

(continued from previous page)

```
void my_first_isr(void *arg)
{
   ... /* some magic happens here */
}

void my_second_isr(void *arg)
{
   ... /* even more magic happens here */
}

void my_isr_installer(void)
{
   ...
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr, MY_FST_ISR_ARG, MY_IRQ_FLAGS);
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_second_isr, MY_SND_ISR_ARG, MY_IRQ_FLAGS);
   ...
}
```

The same restrictions regarding *IRQ_CONNECT* described in *Defining a regular ISR* are applicable here. If CONFIG_SHARED_INTERRUPTS is disabled, the above code will generate a build error. Otherwise, the above code will result in the two ISRs being invoked each time interrupt 24 is triggered.

If CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS is set to a value lower than 2 (current number of clients), a build error will be generated.

If dynamic interrupts are enabled, *irq_connect_dynamic()* will allow sharing interrupts during runtime. Exceeding the configured maximum number of allowed clients will result in a failed assertion.

Dynamically disconnecting an ISR The following code defines two ISRs using the same interrupt number. The second ISR is disconnected during runtime.

```
#define MY_DEV_IRQ 24              /* device uses INTID 24 */
#define MY_DEV_IRQ_PRIO 2          /* device uses interrupt priority 2 */
/*  this argument may be anything */
#define MY_FST_ISR_ARG INT_TO_POINTER(1)
/*  this argument may be anything */
#define MY_SND_ISR_ARG INT_TO_POINTER(2)
#define MY_IRQ_FLAGS 0             /* IRQ flags */

void my_first_isr(void *arg)
{
   ... /* some magic happens here */
}

void my_second_isr(void *arg)
{
   ... /* even more magic happens here */
}

void my_isr_installer(void)
{
   ...
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr, MY_FST_ISR_ARG, MY_IRQ_FLAGS);
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_second_isr, MY_SND_ISR_ARG, MY_IRQ_FLAGS);
   ...
}
```

(continues on next page)

(continued from previous page)

```
void my_isr_uninstaller(void)
{
   ...
   irq_disconnect_dynamic(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr, MY_FST_ISR_ARG, MY_IRQ_
↪FLAGS);
   ...
}
```

The *irq_disconnect_dynamic()* call will result in interrupt 24 becoming unshared, meaning the system will act as if the first *IRQ_CONNECT* call never happened. This behaviour is only allowed if CONFIG_DYNAMIC_INTERRUPTS is enabled, otherwise a linker error will be generated.

Implementation Details Interrupt tables are set up at build time using some special build tools. The details laid out here apply to all architectures except x86, which are covered in the *x86 Details* section below.

The invocation of *IRQ_CONNECT* will declare an instance of struct _isr_list which is placed in a special .intList section. This section is placed in compiled code on precompilation stages only. It is meant to be used by Zephyr script to generate interrupt tables and is removed from the final build. The script implements different parsers to process the data from .intList section and produce the required output.

The default parser generates C arrays filled with arguments and interrupt handlers in a form of addresses directly taken from .intList section entries. It works with all the architectures and compilers (with the exception mentioned above). The limitation of this parser is the fact that after the arrays are generated it is expected for the code not to relocate. Any relocation on this stage may lead to the situation where the entry in the interrupt array is no longer pointing to the function that was expected. It means that this parser, being more compatible is limiting us from using Link Time Optimization.

The local isr declaration parser uses different approach to construct the same arrays at binnary level. All the entries to the arrays are declared and defined locally, directly in the file where *IRQ_CONNECT* is used. They are placed in a section with the unique, synthesized name. The name of the section is then placed in .intList section and it is used to create linker script to properly place the created entry in the right place in the memory. This parser is now limited to the supported architectures and toolchains but in reward it keeps the information about object relations for linker thus allowing the Link Time Optimization.

Implementation using C arrays This is the default configuration available for all Zephyr supported architectures.

Any invocation of *IRQ_CONNECT* will declare an instance of struct _isr_list which is placed in a special .intList section:

```
struct _isr_list {
    /** IRQ line number */
    int32_t irq;
    /** Flags for this IRQ, see ISR_FLAG_* definitions */
    int32_t flags;
    /** ISR to call */
    void *func;
    /** Parameter for non-direct IRQs */
    void *param;
};
```

Zephyr is built in two phases; the first phase of the build produces ${ZEPHYR_PREBUILT_EXECUTABLE}.elf which contains all the entries in the .intList section preceded by a header:

```
struct {
    void *spurious_irq_handler;
    void *sw_irq_handler;
    uint32_t num_isrs;
    uint32_t num_vectors;
    struct _isr_list isrs[];  <- of size num_isrs
};
```

This data consisting of the header and instances of struct _isr_list inside ${ZEPHYR_PREBUILT_EXECUTABLE}.elf is then used by the gen_isr_tables.py script to generate a C file defining a vector table and software ISR table that are then compiled and linked into the final application.

The priority level of any interrupt is not encoded in these tables, instead *IRQ_CONNECT* also has a runtime component which programs the desired priority level of the interrupt to the interrupt controller. Some architectures do not support the notion of interrupt priority, in which case the priority argument is ignored.

Vector Table A vector table is generated when CONFIG_GEN_IRQ_VECTOR_TABLE is enabled. This data structure is used natively by the CPU and is simply an array of function pointers, where each element n corresponds to the IRQ handler for IRQ line n, and the function pointers are:

1. For 'direct' interrupts declared with *IRQ_DIRECT_CONNECT*, the handler function will be placed here.
2. For regular interrupts declared with *IRQ_CONNECT*, the address of the common software IRQ handler is placed here. This code does common kernel interrupt bookkeeping and looks up the ISR and parameter from the software ISR table.
3. For interrupt lines that are not configured at all, the address of the spurious IRQ handler will be placed here. The spurious IRQ handler causes a system fatal error if encountered.

Some architectures (such as the Nios II internal interrupt controller) have a common entry point for all interrupts and do not support a vector table, in which case the CONFIG_GEN_IRQ_VECTOR_TABLE option should be disabled.

Some architectures may reserve some initial vectors for system exceptions and declare this in a table elsewhere, in which case CONFIG_GEN_IRQ_START_VECTOR needs to be set to properly offset the indices in the table.

SW ISR Table This is an array of struct _isr_table_entry:

```
struct _isr_table_entry {
    void *arg;
    void (*isr)(void *);
};
```

This is used by the common software IRQ handler to look up the ISR and its argument and execute it. The active IRQ line is looked up in an interrupt controller register and used to index this table.

Shared SW ISR Table This is an array of struct z_shared_isr_table_entry:

```
struct z_shared_isr_table_entry {
    struct _isr_table_entry clients[CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS];
    size_t client_num;
};
```

This table keeps track of the registered clients for each of the interrupt lines. Whenever an interrupt line becomes shared, z_shared_isr() will replace the currently registered ISR in

_sw_isr_table. This special ISR will iterate through the list of registered clients and invoke the ISRs.

Implementation using linker script This way of prepare and parse .isrList section to implement interrupt vectors arrays is called local isr declaration. The name comes from the fact that all the entries to the arrays that would create interrupt vectors are created locally in place of invocation of *IRQ_CONNECT* macro. Then automatically generated linker scripts are used to place it in the right place in the memory.

This option requires enabling by the choose of ISR_TABLES_LOCAL_DECLARATION. If this configuration is supported by the used architecture and toolchaing the ISR_TABLES_LOCAL_DECLARATION_SUPPORTED is set. See details of this option for the information about currently supported configurations.

Any invocation of *IRQ_CONNECT* or *IRQ_DIRECT_CONNECT* will declare an instance of struct _isr_list_sname which is placde in a special .intList section:

```
struct _isr_list_sname {
    /** IRQ line number */
    int32_t irq;
    /** Flags for this IRQ, see ISR_FLAG_* definitions */
    int32_t flags;
    /** The section name */
    const char sname[];
};
```

Note that the section name is placed in flexible array member. It means that the size of the initialized structure will warry depending on the structure name length. The whole entry is used by the script during the build of the application and has all the information needed for proper interrupt placement.

Beside of the _isr_list_sname the *IRQ_CONNECT* macro generates an entry that would be the part of the interrupt array:

```
struct _isr_table_entry {
    const void *arg;
    void (*isr)(const void *);
};
```

This array is placed in a section with the name saved in _isr_list_sname structure.

The values created by *IRQ_DIRECT_CONNECT* macro depends on the architecture. It can be changed to variable that points to a interrupt handler:

```
static uintptr_t <unique name> = ((uintptr_t)func);
```

Or to actually naked function that implements a jump to the interrupt handler:

```
static void <unique name>(void)
{
    __asm(ARCH_IRQ_VECTOR_JUMP_CODE(func));
}
```

Similar like for *IRQ_CONNECT*, the created variable or function is placed in a section, saved in _isr_list_sname section.

Files generated by the script The interrupt tables generator script creates 3 files: isr_tables.c, isr_tables_swi.ld, and isr_tables_vt.ld.

The isr_tables.c will contain all the structures for interrupts, direct interrupts and shared interrupts (if enabled). This file implements only all the structures that are not implemented by the application, leaving a comment where the interrupt not implemented here can be found.

Then two linker files are used. The isr_tables_vt.ld file is included in place where the interrupt vectors are required to be placed in the selected architecture. The isr_tables_swi.ld file describes the placement of the software interrupt table elements. The separated file is required as it might be placed in writable on nonwritable section, depending on the current configuration.

x86 Details The x86 architecture has a special type of vector table called the Interrupt Descriptor Table (IDT) which must be laid out in a certain way per the x86 processor documentation. It is still fundamentally a vector table, and the *arch/x86/gen_idt.py* tool uses the .intList section to create it. However, on APIC-based systems the indexes in the vector table do not correspond to the IRQ line. The first 32 vectors are reserved for CPU exceptions, and all remaining vectors (up to index 255) correspond to the priority level, in groups of 16. In this scheme, interrupts of priority level 0 will be placed in vectors 32-47, level 1 48-63, and so forth. When the *arch/x86/gen_idt.py* tool is constructing the IDT, when it configures an interrupt it will look for a free vector in the appropriate range for the requested priority level and set the handler there.

On x86 when an interrupt or exception vector is executed by the CPU, there is no foolproof way to determine which vector was fired, so a software ISR table indexed by IRQ line is not used. Instead, the `IRQ_CONNECT` call creates a small assembly language function which calls the common interrupt code in `_interrupt_enter()` with the ISR and parameter as arguments. It is the address of this assembly interrupt stub which gets placed in the IDT. For interrupts declared with `IRQ_DIRECT_CONNECT` the parameterless ISR is placed directly in the IDT.

On systems where the position in the vector table corresponds to the interrupt's priority level, the interrupt controller needs to know at runtime what vector is associated with an IRQ line. *arch/x86/gen_idt.py* additionally creates an _irq_to_interrupt_vector array which maps an IRQ line to its configured vector in the IDT. This is used at runtime by `IRQ_CONNECT` to program the IRQ-to-vector association in the interrupt controller.

For dynamic interrupts, the build must generate some 4-byte dynamic interrupt stubs, one stub per dynamic interrupt in use. The number of stubs is controlled by the `CONFIG_X86_DYNAMIC_IRQ_STUBS` option. Each stub pushes an unique identifier which is then used to fetch the appropriate handler function and parameter out of a table populated when the dynamic interrupt was connected.

Going Beyond the Default Supported Number of Interrupts When generating interrupts in the multi-level configuration, 8-bits per level is the default mask used when determining which level a given interrupt code belongs to. This can become a problem when dealing with CPUs that support more than 255 interrupts per single aggregator. In this case it may be desirable to override these defaults and use a custom number of bits per level. Regardless of how many bits used for each level, the sum of the total bits used between all levels must sum to be less than or equal to 32-bits, fitting into a single 32-bit integer. To modify the bit total per level, override the default 8 in *Kconfig.multilevel* by setting `CONFIG_1ST_LEVEL_INTERRUPT_BITS` for the first level, `CONFIG_2ND_LEVEL_INTERRUPT_BITS` for the second level and `CONFIG_3RD_LEVEL_INTERRUPT_BITS` for the third level. These masks control the length of the bit masks and shift to apply when generating interrupt values, when checking the interrupts level and converting interrupts to a different level. The logic controlling this can be found in `irq_multilevel.h`

Suggested Uses Use a regular or direct ISR to perform interrupt processing that requires a very rapid response, and can be done quickly without blocking.

Note

Interrupt processing that is time consuming, or involves blocking, should be handed off to a thread. See *Offloading ISR Work* for a description of various techniques that can be used in an application.

Configuration Options Related configuration options:

- CONFIG_ISR_STACK_SIZE

Additional architecture-specific and device-specific configuration options also exist.

API Reference

group isr_apis

Defines

IRQ_CONNECT(irq_p, priority_p, isr_p, isr_param_p, flags_p)

Initialize an interrupt handler.

This routine initializes an interrupt handler for an IRQ. The IRQ must be subsequently enabled before the interrupt handler begins servicing interrupts.

Warning

Although this routine is invoked at run-time, all of its arguments must be computable by the compiler at build time.

Parameters

- **irq_p** – IRQ line number.
- **priority_p** – Interrupt priority.
- **isr_p** – Address of interrupt service routine.
- **isr_param_p** – Parameter passed to interrupt service routine.
- **flags_p** – Architecture-specific IRQ configuration flags..

IRQ_DIRECT_CONNECT(irq_p, priority_p, isr_p, flags_p)

Initialize a 'direct' interrupt handler.

This routine initializes an interrupt handler for an IRQ. The IRQ must be subsequently enabled via *irq_enable()* before the interrupt handler begins servicing interrupts.

These ISRs are designed for performance-critical interrupt handling and do not go through common interrupt handling code. They must be implemented in such a way that it is safe to put them directly in the vector table. For ISRs written in C, The *ISR_DIRECT_DECLARE()* macro will do this automatically. For ISRs written in assembly it is entirely up to the developer to ensure that the right steps are taken.

This type of interrupt currently has a few limitations compared to normal Zephyr interrupts:

- No parameters are passed to the ISR.
- No stack switch is done, the ISR will run on the interrupted context's stack, unless the architecture automatically does the stack switch in HW.
- Interrupt locking state is unchanged from how the HW sets it when the ISR runs. On arches that enter ISRs with interrupts locked, they will remain locked.
- Scheduling decisions are now optional, controlled by the return value of ISRs implemented with the *ISR_DIRECT_DECLARE()* macro

- The call into the OS to exit power management idle state is now optional. Normal interrupts always do this before the ISR is run, but when it runs is now controlled by the placement of a *ISR_DIRECT_PM()* macro, or omitted entirely.

Warning

Although this routine is invoked at run-time, all of its arguments must be computable by the compiler at build time.

Parameters

- `irq_p` – IRQ line number.
- `priority_p` – Interrupt priority.
- `isr_p` – Address of interrupt service routine.
- `flags_p` – Architecture-specific IRQ configuration flags.

`ISR_DIRECT_HEADER`()

Common tasks before executing the body of an ISR.

This macro must be at the beginning of all direct interrupts and performs minimal architecture-specific tasks before the ISR itself can run. It takes no arguments and has no return value.

`ISR_DIRECT_FOOTER`(check_reschedule)

Common tasks before exiting the body of an ISR.

This macro must be at the end of all direct interrupts and performs minimal architecture-specific tasks like EOI. It has no return value.

In a normal interrupt, a check is done at end of interrupt to invoke z_swap() logic if the current thread is preemptible and there is another thread ready to run in the kernel's ready queue cache. This is now optional and controlled by the check_reschedule argument. If unsure, set to nonzero. On systems that do stack switching and nested interrupt tracking in software, z_swap() should only be called if this was a non-nested interrupt.

Parameters

- `check_reschedule` – If nonzero, additionally invoke scheduling logic

`ISR_DIRECT_PM`()

Perform power management idle exit logic.

This macro may optionally be invoked somewhere in between IRQ_DIRECT_HEADER() and IRQ_DIRECT_FOOTER() invocations. It performs tasks necessary to exit power management idle state. It takes no parameters and returns no arguments. It may be omitted, but be careful!

`ISR_DIRECT_DECLARE`(name)

Helper macro to declare a direct interrupt service routine.

This will declare the function in a proper way and automatically include the *ISR_DIRECT_FOOTER()* and *ISR_DIRECT_HEADER()* macros. The function should return nonzero status if a scheduling decision should potentially be made. See *ISR_DIRECT_FOOTER()* for more details on the scheduling decision.

For architectures that support 'regular' and 'fast' interrupt types, where these interrupt types require different assembly language handling of registers by the ISR, this will always generate code for the 'fast' interrupt type.

Example usage:

```
ISR_DIRECT_DECLARE(my_isr)
{
        bool done = do_stuff();
        ISR_DIRECT_PM(); // done after do_stuff() due to latency concerns
        if (!done) {
            return 0; // don't bother checking if we have to z_swap()
        }

        k_sem_give(some_sem);
        return 1;
 }
```

Parameters

- `name` – symbol name of the ISR

`irq_lock()`

Lock interrupts.

This routine disables all interrupts on the CPU. It returns an unsigned integer "lock-out key", which is an architecture-dependent indicator of whether interrupts were locked prior to the call. The lock-out key must be passed to *irq_unlock()* to re-enable interrupts.

This routine can be called recursively, as long as the caller keeps track of each lock-out key that is generated. Interrupts are re-enabled by passing each of the keys to *irq_unlock()* in the reverse order they were acquired. (That is, each call to *irq_lock()* must be balanced by a corresponding call to *irq_unlock()*.)

This routine can only be invoked from supervisor mode. Some architectures (for example, ARM) will fail silently if invoked from user mode instead of generating an exception.

Note

This routine must also serve as a memory barrier to ensure the uniprocessor implementation of spinlocks is correct.

Note

This routine can be called by ISRs or by threads. If it is called by a thread, the interrupt lock is thread-specific; this means that interrupts remain disabled only while the thread is running. If the thread performs an operation that allows another thread to run (for example, giving a semaphore or sleeping for N milliseconds), the interrupt lock no longer applies and interrupts may be re-enabled while other processing occurs. When the thread once again becomes the current thread, the kernel re-establishes its interrupt lock; this ensures the thread won't be interrupted until it has explicitly released the interrupt lock it established.

Warning

The lock-out key should never be used to manually re-enable interrupts or to inspect or manipulate the contents of the CPU's interrupt bits.

Returns
An architecture-dependent lock-out key representing the "interrupt disable state" prior to the call.

`irq_unlock`(key)

Unlock interrupts.

This routine reverses the effect of a previous call to *irq_lock()* using the associated lock-out key. The caller must call the routine once for each time it called *irq_lock()*, supplying the keys in the reverse order they were acquired, before interrupts are enabled.

This routine can only be invoked from supervisor mode. Some architectures (for example, ARM) will fail silently if invoked from user mode instead of generating an exception.

Note

This routine must also serve as a memory barrier to ensure the uniprocessor implementation of spinlocks is correct.

Note

Can be called by ISRs.

Parameters

- `key` – Lock-out key generated by *irq_lock()*.

`irq_enable`(irq)

Enable an IRQ.

This routine enables interrupts from source *irq*.

Parameters

- `irq` – IRQ line.

`irq_disable`(irq)

Disable an IRQ.

This routine disables interrupts from source *irq*.

Parameters

- `irq` – IRQ line.

`irq_is_enabled`(irq)

Get IRQ enable state.

This routine indicates if interrupts from source *irq* are enabled.

Parameters

- `irq` – IRQ line.

Returns
interrupt enable state, true or false

Functions

static inline int **irq_connect_dynamic**(unsigned int irq, unsigned int priority, void (*routine)(const void *parameter), const void *parameter, uint32_t flags)

Configure a dynamic interrupt.

Use this instead of *IRQ_CONNECT()* if arguments cannot be known at build time.

Parameters

- **irq** – IRQ line number
- **priority** – Interrupt priority
- **routine** – Interrupt service routine
- **parameter** – ISR parameter
- **flags** – Arch-specific IRQ configuration flags

Returns
The vector assigned to this interrupt

static inline int **irq_disconnect_dynamic**(unsigned int irq, unsigned int priority, void (*routine)(const void *parameter), const void *parameter, uint32_t flags)

Disconnect a dynamic interrupt.

Use this in conjunction with shared interrupts to remove a routine/parameter pair from the list of clients using the same interrupt line. If the interrupt is not being shared then the associated _sw_isr_table entry will be replaced by (NULL, z_irq_spurious) (default entry).

Parameters

- **irq** – IRQ line number
- **priority** – Interrupt priority
- **routine** – Interrupt service routine
- **parameter** – ISR parameter
- **flags** – Arch-specific IRQ configuration flags

Returns
0 in case of success, negative value otherwise

bool **k_is_in_isr**(void)

Determine if code is running at interrupt level.

This routine allows the caller to customize its actions, depending on whether it is a thread or an ISR.

Function properties (list may not be complete)
isr-ok

Returns
false if invoked by a thread.

Returns
true if invoked by an ISR.

int `k_is_preempt_thread`(void)

Determine if code is running in a preemptible thread.

This routine allows the caller to customize its actions, depending on whether it can be preempted by another thread. The routine returns a 'true' value if all of the following conditions are met:

- The code is running in a thread, not at ISR.
- The thread's priority is in the preemptible range.
- The thread has not locked the scheduler.

Function properties (list may not be complete)

isr-ok

Returns

0 if invoked by an ISR or by a cooperative thread.

Returns

Non-zero if invoked by a preemptible thread.

static inline bool `k_is_pre_kernel`(void)

Test whether startup is in the before-main-task phase.

This routine allows the caller to customize its actions, depending on whether it being invoked before the kernel is fully active.

Function properties (list may not be complete)

isr-ok

Returns

true if invoked before post-kernel initialization

Returns

false if invoked during/after post-kernel initialization

Polling API

The polling API is used to wait concurrently for any one of multiple conditions to be fulfilled.

- *Concepts*
- *Implementation*
  - *Using k_poll()*
  - *Using k_poll_signal_raise()*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts The polling API's main function is *k_poll()*, which is very similar in concept to the POSIX *poll()* function, except that it operates on kernel objects rather than on file descriptors.

The polling API allows a single thread to wait concurrently for one or more conditions to be fulfilled without actively looking at each one individually.

There is a limited set of such conditions:

- a semaphore becomes available
- a kernel FIFO contains data ready to be retrieved
- a kernel message queue contains data ready to be retrieved
- a kernel pipe contains data ready to be retrieved
- a poll signal is raised

A thread that wants to wait on multiple conditions must define an array of **poll events**, one for each condition.

All events in the array must be initialized before the array can be polled on.

Each event must specify which **type** of condition must be satisfied so that its state is changed to signal the requested condition has been met.

Each event must specify what **kernel object** it wants the condition to be satisfied.

Each event must specify which **mode** of operation is used when the condition is satisfied.

Each event can optionally specify a **tag** to group multiple events together, to the user's discretion.

Apart from the kernel objects, there is also a **poll signal** pseudo-object type that be directly signaled.

The *k_poll()* function returns as soon as one of the conditions it is waiting for is fulfilled. It is possible for more than one to be fulfilled when *k_poll()* returns, if they were fulfilled before *k_poll()* was called, or due to the preemptive multi-threading nature of the kernel. The caller must look at the state of all the poll events in the array to figure out which ones were fulfilled and what actions to take.

Currently, there is only one mode of operation available: the object is not acquired. As an example, this means that when *k_poll()* returns and the poll event states that the semaphore is available, the caller of *k_poll()* must then invoke *k_sem_take()* to take ownership of the semaphore. If the semaphore is contested, there is no guarantee that it will be still available when *k_sem_take()* is called.

Implementation

Using k_poll() The main API is *k_poll()*, which operates on an array of poll events of type *k_poll_event*. Each entry in the array represents one event a call to *k_poll()* will wait for its condition to be fulfilled.

Poll events can be initialized using either the runtime initializers *K_POLL_EVENT_INITIALIZER()* or *k_poll_event_init()*, or the static initializer *K_POLL_EVENT_STATIC_INITIALIZER()*. An object that matches the **type** specified must be passed to the initializers. The **mode** *must* be set to *K_POLL_MODE_NOTIFY_ONLY*. The state *must* be set to *K_POLL_STATE_NOT_READY* (the initializers take care of this). The user **tag** is optional and completely opaque to the API: it is there to help a user to group similar events together. Being optional, it is passed to the static initializer, but not the runtime ones for performance reasons. If using runtime initializers, the user must set it separately in the *k_poll_event* data structure. If an event in the array is to be ignored, most likely temporarily, its type can be set to *K_POLL_TYPE_IGNORE*.

```
struct k_poll_event events[4] = {
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_SEM_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_sem, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_FIFO_DATA_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_fifo, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_MSGQ_DATA_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_msgq, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_PIPE_DATA_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_pipe, 0),
};
```

or at runtime

```
struct k_poll_event events[4];
void some_init(void)
{
    k_poll_event_init(&events[0],
                      K_POLL_TYPE_SEM_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_sem);

    k_poll_event_init(&events[1],
                      K_POLL_TYPE_FIFO_DATA_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_fifo);

    k_poll_event_init(&events[2],
                      K_POLL_TYPE_MSGQ_DATA_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_msgq);

    k_poll_event_init(&events[3],
                      K_POLL_TYPE_PIPE_DATA_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_pipe);

    // tags are left uninitialized if unused
}
```

After the events are initialized, the array can be passed to *k_poll()*. A timeout can be specified to wait only for a specified amount of time, or the special values *K_NO_WAIT* and *K_FOREVER* to either not wait or wait until an event condition is satisfied and not sooner.

A list of pollers is offered on each semaphore or FIFO and as many events can wait in it as the app wants. Notice that the waiters will be served in first-come-first-serve order, not in priority order.

In case of success, *k_poll()* returns 0. If it times out, it returns -*EAGAIN*.

```
// assume there is no contention on this semaphore and FIFO
// -EADDRINUSE will not occur; the semaphore and/or data will be available

void do_stuff(void)
{
    rc = k_poll(events, ARRAY_SIZE(events), K_MSEC(1000));
    if (rc == 0) {
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
            k_sem_take(events[0].sem, 0);
```

(continues on next page)

(continued from previous page)

```
        } else if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
            data = k_fifo_get(events[1].fifo, 0);
            // handle data
        } else if (events[2].state == K_POLL_STATE_MSGQ_DATA_AVAILABLE) {
            ret = k_msgq_get(events[2].msgq, buf, K_NO_WAIT);
            // handle data
        } else if (events[3].state == K_POLL_STATE_PIPE_DATA_AVAILABLE) {
            ret = k_pipe_get(events[3].pipe, buf, bytes_to_read, &bytes_read, min_xfer, K_
↪NO_WAIT);
            // handle data
        }
    } else {
        // handle timeout
    }
}
```

When *k_poll()* is called in a loop, the events state must be reset to *K_POLL_STATE_NOT_READY* by the user.

```
void do_stuff(void)
{
    for(;;) {
        rc = k_poll(events, ARRAY_SIZE(events), K_FOREVER);
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
            k_sem_take(events[0].sem, 0);
        } else if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
            data = k_fifo_get(events[1].fifo, 0);
            // handle data
        } else if (events[2].state == K_POLL_STATE_MSGQ_DATA_AVAILABLE) {
            ret = k_msgq_get(events[2].msgq, buf, K_NO_WAIT);
            // handle data
        } else if (events[3].state == K_POLL_STATE_PIPE_DATA_AVAILABLE) {
            ret = k_pipe_get(events[3].pipe, buf, bytes_to_read, &bytes_read, min_xfer, K_
↪NO_WAIT);
            // handle data
        }
        events[0].state = K_POLL_STATE_NOT_READY;
        events[1].state = K_POLL_STATE_NOT_READY;
        events[2].state = K_POLL_STATE_NOT_READY;
        events[3].state = K_POLL_STATE_NOT_READY;
    }
}
```

Using k_poll_signal_raise() One of the types of events is *K_POLL_TYPE_SIGNAL*: this is a "direct" signal to a poll event. This can be seen as a lightweight binary semaphore only one thread can wait for.

A poll signal is a separate object of type *k_poll_signal* that must be attached to a k_poll_event, similar to a semaphore or FIFO. It must first be initialized either via *K_POLL_SIGNAL_INITIALIZER()* or *k_poll_signal_init()*.

```
struct k_poll_signal signal;
void do_stuff(void)
{
    k_poll_signal_init(&signal);
}
```

It is signaled via the *k_poll_signal_raise()* function. This function takes a user **result** parameter that is opaque to the API and can be used to pass extra information to the thread waiting on the event.

```
struct k_poll_signal signal;

// thread A
void do_stuff(void)
{
    k_poll_signal_init(&signal);

    struct k_poll_event events[1] = {
        K_POLL_EVENT_INITIALIZER(K_POLL_TYPE_SIGNAL,
                                 K_POLL_MODE_NOTIFY_ONLY,
                                 &signal),
    };

    k_poll(events, 1, K_FOREVER);

    int signaled, result;

    k_poll_signal_check(&signal, &signaled, &result);

    if (signaled && (result == 0x1337)) {
        // A-OK!
    } else {
        // weird error
    }
}

// thread B
void signal_do_stuff(void)
{
    k_poll_signal_raise(&signal, 0x1337);
}
```

If the signal is to be polled in a loop, *both* its event state must be reset to *K_POLL_STATE_NOT_READY* *and* its `result` must be reset using *k_poll_signal_reset()* on each iteration if it has been signaled.

```
struct k_poll_signal signal;
void do_stuff(void)
{
    k_poll_signal_init(&signal);

    struct k_poll_event events[1] = {
        K_POLL_EVENT_INITIALIZER(K_POLL_TYPE_SIGNAL,
                                 K_POLL_MODE_NOTIFY_ONLY,
                                 &signal),
    };

    for (;;) {
        k_poll(events, 1, K_FOREVER);

        int signaled, result;

        k_poll_signal_check(&signal, &signaled, &result);

        if (signaled && (result == 0x1337)) {
            // A-OK!
        } else {
            // weird error
        }

        k_poll_signal_reset(signal);
        events[0].state = K_POLL_STATE_NOT_READY;
```

(continues on next page)

(continued from previous page)

```
    }
}
```

Note that poll signals are not internally synchronized. A *k_poll()* call that is passed a signal will return after any code in the system calls *k_poll_signal_raise()*. But if the signal is being externally managed and reset via *k_poll_signal_init()*, it is possible that by the time the application checks, the event state may no longer be equal to *K_POLL_STATE_SIGNALED*, and a (naive) application will miss events. Best practice is always to reset the signal only from within the thread invoking the *k_poll()* loop, or else to use some other event type which tracks event counts: semaphores and FIFOs are more error-proof in this sense because they can't "miss" events, architecturally.

Suggested Uses Use *k_poll()* to consolidate multiple threads that would be pending on one object each, saving possibly large amounts of stack space.

Use a poll signal as a lightweight binary semaphore if only one thread pends on it.

Note

Because objects are only signaled if no other thread is waiting for them to become available and only one thread can poll on a specific object, polling is best used when objects are not subject of contention between multiple threads, basically when a single thread operates as a main "server" or "dispatcher" for multiple objects and is the only one trying to acquire these objects.

Functions

void k_poll_event_init(struct *k_poll_event* *event, uint32_t type, int mode, void *obj)

Initialize one struct *k_poll_event* instance.

After this routine is called on a poll event, the event it ready to be placed in an event array to be passed to *k_poll()*.

Parameters

- event – The event to initialize.
- type – A bitfield of the types of event, from the K_POLL_TYPE_xxx values. Only values that apply to the same object being polled can be used together. Choosing K_POLL_TYPE_IGNORE disables the event.
- mode – Future. Use K_POLL_MODE_NOTIFY_ONLY.
- obj – Kernel object or poll signal.

int k_poll(struct *k_poll_event* *events, int num_events, *k_timeout_t* timeout)

Wait for one or many of multiple poll events to occur.

This routine allows a thread to wait concurrently for one or many of multiple poll events to have occurred. Such events can be a kernel object being available, like a semaphore, or a poll signal event.

When an event notifies that a kernel object is available, the kernel object is not "given" to the thread calling *k_poll()*: it merely signals the fact that the object was available when the *k_poll()* call was in effect. Also, all threads trying to acquire an object the regular way, i.e. by pending on the object, have precedence over the thread polling on the object. This means that the polling thread will never get the poll event on an object until the object becomes available and its pend queue is empty. For this reason, the *k_poll()* call is more effective when the objects being polled only have one thread, the polling thread, trying to acquire them.

When *k_poll()* returns 0, the caller should loop on all the events that were passed to *k_poll()* and check the state field for the values that were expected and take the associated actions.

Before being reused for another call to *k_poll()*, the user has to reset the state field to K_POLL_STATE_NOT_READY.

When called from user mode, a temporary memory allocation is required from the caller's resource pool.

Parameters

- `events` – An array of events to be polled for.
- `num_events` – The number of events in the array.
- `timeout` – Waiting period for an event to be ready, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- `0` – One or more events are ready.
- `-EAGAIN` – Waiting period timed out.
- `-EINTR` – Polling has been interrupted, e.g. with *k_queue_cancel_wait()*. All output events are still set and valid, cancelled event(s) will be set to K_POLL_STATE_CANCELLED. In other words, -EINTR status means that at least one of output events is K_POLL_STATE_CANCELLED.
- `-ENOMEM` – Thread resource pool insufficient memory (user mode only)
- `-EINVAL` – Bad parameters (user mode only)

void k_poll_signal_init(struct *k_poll_signal* *sig)

Initialize a poll signal object.

Ready a poll signal object to be signaled via *k_poll_signal_raise()*.

Parameters

- `sig` – A poll signal.

void k_poll_signal_reset(struct *k_poll_signal* *sig)

Reset a poll signal object's state to unsignaled.

Parameters

- `sig` – A poll signal object

void **k_poll_signal_check**(struct *k_poll_signal* *sig, unsigned int *signaled, int *result)

Fetch the signaled state and result value of a poll signal.

Parameters

- **sig** – A poll signal object
- **signaled** – An integer buffer which will be written nonzero if the object was signaled
- **result** – An integer destination buffer which will be written with the result value if the object was signaled, or an undefined value if it was not.

int **k_poll_signal_raise**(struct *k_poll_signal* *sig, int result)

Signal a poll signal object.

This routine makes ready a poll signal, which is basically a poll event of type K_POLL_TYPE_SIGNAL. If a thread was polling on that event, it will be made ready to run. A *result* value can be specified.

The poll signal contains a 'signaled' field that, when set by *k_poll_signal_raise()*, stays set until the user sets it back to 0 with *k_poll_signal_reset()*. It thus has to be reset by the user before being passed again to *k_poll()* or *k_poll()* will consider it being signaled, and will return immediately.

Note

The result is stored and the 'signaled' field is set even if this function returns an error indicating that an expiring poll was not notified. The next *k_poll()* will detect the missed raise.

Parameters

- **sig** – A poll signal.
- **result** – The value to store in the result field of the signal.

Return values

- **0** – The signal was delivered successfully.
- **-EAGAIN** – The polling thread's timeout is in the process of expiring.

struct **k_poll_signal**

#include <kernel.h>

Public Members

sys_dlist_t **poll_events**

PRIVATE - DO NOT TOUCH.

unsigned int **signaled**

1 if the event has been signaled, 0 otherwise.

Stays set to 1 until user resets it to 0.

int **result**
custom result value passed to *k_poll_signal_raise()* if needed

struct **k_poll_event**
#include <kernel.h> Poll Event.

Public Members

struct z_poller ***poller**
PRIVATE - DO NOT TOUCH.

uint32_t **tag**
optional user-specified tag, opaque, untouched by the API

uint32_t **type**
bitfield of event types (bitwise-ORed K_POLL_TYPE_xxx values)

uint32_t **state**
bitfield of event states (bitwise-ORed K_POLL_STATE_xxx values)

uint32_t **mode**
mode of operation, from enum k_poll_modes

uint32_t **unused**
unused bits in 32-bit word

union k_poll_event
per-type data

Semaphores

A *semaphore* is a kernel object that implements a traditional counting semaphore.

- *Concepts*
- *Implementation*
  - *Defining a Semaphore*
  - *Giving a Semaphore*
  - *Taking a Semaphore*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*
- *User Mode Semaphore API Reference*

Concepts Any number of semaphores can be defined (limited only by available RAM). Each semaphore is referenced by its memory address.

A semaphore has the following key properties:

- A **count** that indicates the number of times the semaphore can be taken. A count of zero indicates that the semaphore is unavailable.
- A **limit** that indicates the maximum value the semaphore's count can reach.

A semaphore must be initialized before it can be used. Its count must be set to a non-negative value that is less than or equal to its limit.

A semaphore may be **given** by a thread or an ISR. Giving the semaphore increments its count, unless the count is already equal to the limit.

A semaphore may be **taken** by a thread. Taking the semaphore decrements its count, unless the semaphore is unavailable (i.e. at zero). When a semaphore is unavailable a thread may choose to wait for it to be given. Any number of threads may wait on an unavailable semaphore simultaneously. When the semaphore is given, it is taken by the highest priority thread that has waited longest.

Note

You may initialize a "full" semaphore (count equal to limit) to limit the number of threads able to execute the critical section at the same time. You may also initialize an empty semaphore (count equal to 0, with a limit greater than 0) to create a gate through which no waiting thread may pass until the semaphore is incremented. All standard use cases of the common semaphore are supported.

Note

The kernel does allow an ISR to take a semaphore, however the ISR must not attempt to wait if the semaphore is unavailable.

Implementation

Defining a Semaphore A semaphore is defined using a variable of type `k_sem`. It must then be initialized by calling *k_sem_init()*.

The following code defines a semaphore, then configures it as a binary semaphore by setting its count to 0 and its limit to 1.

```
struct k_sem my_sem;

k_sem_init(&my_sem, 0, 1);
```

Alternatively, a semaphore can be defined and initialized at compile time by calling *K_SEM_DEFINE*.

The following code has the same effect as the code segment above.

```
K_SEM_DEFINE(my_sem, 0, 1);
```

Giving a Semaphore A semaphore is given by calling *k_sem_give()*.

The following code builds on the example above, and gives the semaphore to indicate that a unit of data is available for processing by a consumer thread.

```
void input_data_interrupt_handler(void *arg)
{
    /* notify thread that data is available */
    k_sem_give(&my_sem);

    ...
}
```

Taking a Semaphore A semaphore is taken by calling *k_sem_take()*.

The following code builds on the example above, and waits up to 50 milliseconds for the semaphore to be given. A warning is issued if the semaphore is not obtained in time.

```
void consumer_thread(void)
{
    ...

    if (k_sem_take(&my_sem, K_MSEC(50)) != 0) {
        printk("Input data not available!");
    } else {
        /* fetch available data */
        ...
    }
    ...
}
```

Suggested Uses Use a semaphore to control access to a set of resources by multiple threads.

Use a semaphore to synchronize processing between a producing and consuming threads or ISRs.

Configuration Options Related configuration options:

- None.

API Reference

group `semaphore_apis`

Defines

`K_SEM_MAX_LIMIT`

Maximum limit value allowed for a semaphore.

This is intended for use when a semaphore does not have an explicit maximum limit, and instead is just used for counting purposes.

K_SEM_DEFINE(name, initial_count, count_limit)

Statically define and initialize a semaphore.

The semaphore can be accessed outside the module where it is defined using:

```
extern struct k_sem <name>;
```

Parameters

- **name** – Name of the semaphore.
- **initial_count** – Initial semaphore count.
- **count_limit** – Maximum permitted semaphore count.

Functions

int k_sem_init(struct k_sem *sem, unsigned int initial_count, unsigned int limit)

Initialize a semaphore.

This routine initializes a semaphore object, prior to its first use.

See also

K_SEM_MAX_LIMIT

Parameters

- **sem** – Address of the semaphore.
- **initial_count** – Initial semaphore count.
- **limit** – Maximum permitted semaphore count.

Return values

- **0** – Semaphore created successfully
- **-EINVAL** – Invalid values

int k_sem_take(struct k_sem *sem, *k_timeout_t* timeout)

Take a semaphore.

This routine takes *sem*.

Function properties (list may not be complete)

isr-ok

Note

timeout must be set to K_NO_WAIT if called from ISR.

Parameters

- **sem** – Address of the semaphore.
- **timeout** – Waiting period to take the semaphore, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- `0` – Semaphore taken.
- `-EBUSY` – Returned without waiting.
- `-EAGAIN` – Waiting period timed out, or the semaphore was reset during the waiting period.

void `k_sem_give`(struct k_sem *sem)

Give a semaphore.

This routine gives *sem*, unless the semaphore is already at its maximum permitted count.

Function properties (list may not be complete)

isr-ok

Parameters

- `sem` – Address of the semaphore.

void `k_sem_reset`(struct k_sem *sem)

Resets a semaphore's count to zero.

This routine sets the count of *sem* to zero. Any outstanding semaphore takes will be aborted with -EAGAIN.

Parameters

- `sem` – Address of the semaphore.

unsigned int `k_sem_count_get`(struct k_sem *sem)

Get a semaphore's count.

This routine returns the current count of *sem*.

Parameters

- `sem` – Address of the semaphore.

Returns

Current semaphore count.

User Mode Semaphore API Reference The sys_sem exists in user memory working as counter semaphore for user mode thread when user mode enabled. When user mode isn't enabled, sys_sem behaves like k_sem.

group `user_semaphore_apis`

Defines

`SYS_SEM_DEFINE`(_name, _initial_count, _count_limit)

Statically define and initialize a sys_sem.

The semaphore can be accessed outside the module where it is defined using:

```
extern struct sys_sem <name>;
```

Route this to memory domains using K_APP_DMEM().

Parameters

- **_name** – Name of the semaphore.
- **_initial_count** – Initial semaphore count.
- **_count_limit** – Maximum permitted semaphore count.

Functions

int **sys_sem_init**(struct sys_sem *sem, unsigned int initial_count, unsigned int limit)

Initialize a semaphore.

This routine initializes a semaphore instance, prior to its first use.

Parameters

- **sem** – Address of the semaphore.
- **initial_count** – Initial semaphore count.
- **limit** – Maximum permitted semaphore count.

Return values

- **0** – Initial success.
- **-EINVAL** – Bad parameters, the value of limit should be located in (0, INT_MAX] and initial_count shouldn't be greater than limit.

int **sys_sem_give**(struct sys_sem *sem)

Give a semaphore.

This routine gives *sem*, unless the semaphore is already at its maximum permitted count.

Parameters

- **sem** – Address of the semaphore.

Return values

- **0** – Semaphore given.
- **-EINVAL** – Parameter address not recognized.
- **-EACCES** – Caller does not have enough access.
- **-EAGAIN** – Count reached Maximum permitted count and try again.

int **sys_sem_take**(struct sys_sem *sem, *k_timeout_t* timeout)

Take a sys_sem.

This routine takes *sem*.

Parameters

- **sem** – Address of the sys_sem.
- **timeout** – Waiting period to take the sys_sem, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- **0** – sys_sem taken.
- **-EINVAL** – Parameter address not recognized.
- **-ETIMEDOUT** – Waiting period timed out.
- **-EACCES** – Caller does not have enough access.

unsigned int **sys_sem_count_get**(struct sys_sem *sem)

Get sys_sem's value.

This routine returns the current value of *sem*.

Parameters

- **sem** – Address of the sys_sem.

Returns

Current value of sys_sem.

Mutexes

A *mutex* is a kernel object that implements a traditional reentrant mutex. A mutex allows multiple threads to safely share an associated hardware or software resource by ensuring mutually exclusive access to the resource.

- *Concepts*
  - *Reentrant Locking*
  - *Priority Inheritance*
- *Implementation*
  - *Defining a Mutex*
  - *Locking a Mutex*
  - *Unlocking a Mutex*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*
- *Futex API Reference*
- *User Mode Mutex API Reference*

Concepts Any number of mutexes can be defined (limited only by available RAM). Each mutex is referenced by its memory address.

A mutex has the following key properties:

- A **lock count** that indicates the number of times the mutex has been locked by the thread that has locked it. A count of zero indicates that the mutex is unlocked.
- An **owning thread** that identifies the thread that has locked the mutex, when it is locked.

A mutex must be initialized before it can be used. This sets its lock count to zero.

A thread that needs to use a shared resource must first gain exclusive rights to access it by **locking** the associated mutex. If the mutex is already locked by another thread, the requesting thread may choose to wait for the mutex to be unlocked.

After locking a mutex, the thread may safely use the associated resource for as long as needed; however, it is considered good practice to hold the lock for as short a time as possible to avoid negatively impacting other threads that want to use the resource. When the thread no longer needs the resource it must **unlock** the mutex to allow other threads to use the resource.

Any number of threads may wait on a locked mutex simultaneously. When the mutex becomes unlocked it is then locked by the highest-priority thread that has waited the longest.

Note

Mutex objects are *not* designed for use by ISRs.

Reentrant Locking A thread is permitted to lock a mutex it has already locked. This allows the thread to access the associated resource at a point in its execution when the mutex may or may not already be locked.

A mutex that is repeatedly locked by a thread must be unlocked an equal number of times before the mutex becomes fully unlocked so it can be claimed by another thread.

Priority Inheritance The thread that has locked a mutex is eligible for *priority inheritance*. This means the kernel will *temporarily* elevate the thread's priority if a higher priority thread begins waiting on the mutex. This allows the owning thread to complete its work and release the mutex more rapidly by executing at the same priority as the waiting thread. Once the mutex has been unlocked, the unlocking thread resets its priority to the level it had before locking that mutex.

Note

The `CONFIG_PRIORITY_CEILING` configuration option limits how high the kernel can raise a thread's priority due to priority inheritance. The default value of 0 permits unlimited elevation.

The owning thread's base priority is saved in the mutex when it obtains the lock. Each time a higher priority thread waits on a mutex, the kernel adjusts the owning thread's priority. When the owning thread releases the lock (or if the high priority waiting thread times out), the kernel restores the thread's base priority from the value saved in the mutex.

This works well for priority inheritance as long as only one locked mutex is involved. However, if multiple mutexes are involved, sub-optimal behavior will be observed if the mutexes are not unlocked in the reverse order to which the owning thread's priority was previously raised. Consequently it is recommended that a thread lock only a single mutex at a time when multiple mutexes are shared between threads of different priorities.

Implementation

Defining a Mutex A mutex is defined using a variable of type *k_mutex*. It must then be initialized by calling *k_mutex_init()*.

The following code defines and initializes a mutex.

```
struct k_mutex my_mutex;

k_mutex_init(&my_mutex);
```

Alternatively, a mutex can be defined and initialized at compile time by calling *K_MUTEX_DEFINE*.

The following code has the same effect as the code segment above.

```
K_MUTEX_DEFINE(my_mutex);
```

Locking a Mutex A mutex is locked by calling *k_mutex_lock()*.

The following code builds on the example above, and waits indefinitely for the mutex to become available if it is already locked by another thread.

```
k_mutex_lock(&my_mutex, K_FOREVER);
```

The following code waits up to 100 milliseconds for the mutex to become available, and gives a warning if the mutex does not become available.

```
if (k_mutex_lock(&my_mutex, K_MSEC(100)) == 0) {
    /* mutex successfully locked */
} else {
    printf("Cannot lock XYZ display\n");
}
```

Unlocking a Mutex A mutex is unlocked by calling *k_mutex_unlock()*.

The following code builds on the example above, and unlocks the mutex that was previously locked by the thread.

```
k_mutex_unlock(&my_mutex);
```

Suggested Uses Use a mutex to provide exclusive access to a resource, such as a physical device.

Configuration Options Related configuration options:

- CONFIG_PRIORITY_CEILING

API Reference

group mutex_apis

Defines

K_MUTEX_DEFINE(name)

Statically define and initialize a mutex.

The mutex can be accessed outside the module where it is defined using:

```
extern struct k_mutex <name>;
```

Parameters

- **name** – Name of the mutex.

Functions

int k_mutex_init(struct *k_mutex* *mutex)

Initialize a mutex.

This routine initializes a mutex object, prior to its first use.

Upon completion, the mutex is available and does not have an owner.

Parameters

- **mutex** – Address of the mutex.

Return values

0 – Mutex object created

int **k_mutex_lock**(struct *k_mutex* *mutex, *k_timeout_t* timeout)

Lock a mutex.

This routine locks *mutex*. If the mutex is locked by another thread, the calling thread waits until the mutex becomes available or until a timeout occurs.

A thread is permitted to lock a mutex it has already locked. The operation completes immediately and the lock count is increased by 1.

Mutexes may not be locked in ISRs.

Parameters

- **mutex** – Address of the mutex.
- **timeout** – Waiting period to lock the mutex, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- **0** – Mutex locked.
- **-EBUSY** – Returned without waiting.
- **-EAGAIN** – Waiting period timed out.

int **k_mutex_unlock**(struct *k_mutex* *mutex)

Unlock a mutex.

This routine unlocks *mutex*. The mutex must already be locked by the calling thread.

The mutex cannot be claimed by another thread until it has been unlocked by the calling thread as many times as it was previously locked by that thread.

Mutexes may not be unlocked in ISRs, as mutexes must only be manipulated in thread context due to ownership and priority inheritance semantics.

Parameters

- **mutex** – Address of the mutex.

Return values

- **0** – Mutex unlocked.
- **-EPERM** – The current thread does not own the mutex
- **-EINVAL** – The mutex is not locked

struct **k_mutex**

#include <*kernel.h*> Mutex Structure.

Public Members

_wait_q_t **wait_q**

Mutex wait queue.

struct *k_thread* ***owner**

Mutex owner.

uint32_t **lock_count**
: Current lock count.

int **owner_orig_prio**
: Original thread priority.

Futex API Reference k_futex is a lightweight mutual exclusion primitive designed to minimize kernel involvement. Uncontended operation relies only on atomic access to shared memory. k_futex are tracked as kernel objects and can live in user memory so that any access bypasses the kernel object permission management mechanism.

group **futex_apis**

Functions

int **k_futex_wait**(struct k_futex *futex, int expected, *k_timeout_t* timeout)
: Pend the current thread on a futex.

  Tests that the supplied futex contains the expected value, and if so, goes to sleep until some other thread calls *k_futex_wake()* on it.

  Parameters

  - **futex** – Address of the futex.
  - **expected** – Expected value of the futex, if it is different the caller will not wait on it.
  - **timeout** – Waiting period on the futex, or one of the special values K_NO_WAIT or K_FOREVER.

  Return values

  - **-EACCES** – Caller does not have read access to futex address.
  - **-EAGAIN** – If the futex value did not match the expected parameter.
  - **-EINVAL** – Futex parameter address not recognized by the kernel.
  - **-ETIMEDOUT** – Thread woke up due to timeout and not a futex wakeup.
  - **0** – if the caller went to sleep and was woken up. The caller should check the futex's value on wakeup to determine if it needs to block again.

int **k_futex_wake**(struct k_futex *futex, bool wake_all)
: Wake one/all threads pending on a futex.

  Wake up the highest priority thread pending on the supplied futex, or wakeup all the threads pending on the supplied futex, and the behavior depends on wake_all.

  Parameters

  - **futex** – Futex to wake up pending threads.
  - **wake_all** – If true, wake up all pending threads; If false, wakeup the highest priority thread.

  Return values

  - **-EACCES** – Caller does not have access to the futex address.
  - **-EINVAL** – Futex parameter address not recognized by the kernel.
  - **Number** – of threads that were woken up.

User Mode Mutex API Reference sys_mutex behaves almost exactly like k_mutex, with the added advantage that a sys_mutex instance can reside in user memory. When user mode isn't enabled, sys_mutex behaves like k_mutex.

group `user_mutex_apis`

Defines

`SYS_MUTEX_DEFINE`(name)

Statically define and initialize a sys_mutex.

The mutex can be accessed outside the module where it is defined using:

```
extern struct sys_mutex <name>;
```

Route this to memory domains using K_APP_DMEM().

Parameters

- `name` – Name of the mutex.

Functions

static inline void `sys_mutex_init`(struct sys_mutex *mutex)

Initialize a mutex.

This routine initializes a mutex object, prior to its first use.

Upon completion, the mutex is available and does not have an owner.

This routine is only necessary to call when userspace is disabled and the mutex was not created with *SYS_MUTEX_DEFINE()*.

Parameters

- `mutex` – Address of the mutex.

static inline int `sys_mutex_lock`(struct sys_mutex *mutex, *k_timeout_t* timeout)

Lock a mutex.

This routine locks *mutex*. If the mutex is locked by another thread, the calling thread waits until the mutex becomes available or until a timeout occurs.

A thread is permitted to lock a mutex it has already locked. The operation completes immediately and the lock count is increased by 1.

Parameters

- `mutex` – Address of the mutex, which may reside in user memory
- `timeout` – Waiting period to lock the mutex, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- `0` – Mutex locked.
- `-EBUSY` – Returned without waiting.
- `-EAGAIN` – Waiting period timed out.
- `-EACCES` – Caller has no access to provided mutex address
- `-EINVAL` – Provided mutex not recognized by the kernel

static inline int **sys_mutex_unlock**(struct sys_mutex *mutex)

Unlock a mutex.

This routine unlocks *mutex*. The mutex must already be locked by the calling thread.

The mutex cannot be claimed by another thread until it has been unlocked by the calling thread as many times as it was previously locked by that thread.

Parameters

- `mutex` – Address of the mutex, which may reside in user memory

Return values

- `0` – Mutex unlocked
- `-EACCES` – Caller has no access to provided mutex address
- `-EINVAL` – Provided mutex not recognized by the kernel or mutex wasn't locked
- `-EPERM` – Caller does not own the mutex

Condition Variables

A *condition variable* is a synchronization primitive that enables threads to wait until a particular condition occurs.

- *Concepts*
- *Implementation*
  - *Defining a Condition Variable*
  - *Waiting on a Condition Variable*
  - *Signaling a Condition Variable*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of condition variables can be defined (limited only by available RAM). Each condition variable is referenced by its memory address.

To wait for a condition to become true, a thread can make use of a condition variable.

A condition variable is basically a queue of threads that threads can put themselves on when some state of execution (i.e., some condition) is not as desired (by waiting on the condition). The function *k_condvar_wait()* performs atomically the following steps;

1. Releases the last acquired mutex.
2. Puts the current thread in the condition variable queue.

Some other thread, when it changes said state, can then wake one (or more) of those waiting threads and thus allow them to continue by signaling on the condition using *k_condvar_signal()* or *k_condvar_broadcast()* then it:

1. Re-acquires the mutex previously released.
2. Returns from *k_condvar_wait()*.

A condition variable must be initialized before it can be used.

Implementation

Defining a Condition Variable A condition variable is defined using a variable of type k_condvar. It must then be initialized by calling *k_condvar_init()*.

The following code defines a condition variable:

```
struct k_condvar my_condvar;

k_condvar_init(&my_condvar);
```

Alternatively, a condition variable can be defined and initialized at compile time by calling *K_CONDVAR_DEFINE*.

The following code has the same effect as the code segment above.

```
K_CONDVAR_DEFINE(my_condvar);
```

Waiting on a Condition Variable A thread can wait on a condition by calling *k_condvar_wait()*.

The following code waits on the condition variable.

```
K_MUTEX_DEFINE(mutex);
K_CONDVAR_DEFINE(condvar)

int main(void)
{
    k_mutex_lock(&mutex, K_FOREVER);

    /* block this thread until another thread signals cond. While
     * blocked, the mutex is released, then re-acquired before this
     * thread is woken up and the call returns.
     */
    k_condvar_wait(&condvar, &mutex, K_FOREVER);
    ...
    k_mutex_unlock(&mutex);
}
```

Signaling a Condition Variable A condition variable is signaled on by calling *k_condvar_signal()* for one thread or by calling *k_condvar_broadcast()* for multiple threads.

The following code builds on the example above.

```
void worker_thread(void)
{
    k_mutex_lock(&mutex, K_FOREVER);

    /*
     * Do some work and fulfill the condition
     */
    ...
    ...
    k_condvar_signal(&condvar);
    k_mutex_unlock(&mutex);
}
```

Suggested Uses Use condition variables with a mutex to signal changing states (conditions) from one thread to another thread. Condition variables are not the condition itself and they are not events. The condition is contained in the surrounding programming logic.

Mutexes alone are not designed for use as a notification/synchronization mechanism. They are meant to provide mutually exclusive access to a shared resource only.

Configuration Options Related configuration options:

- None.

Related code samples

Condition Variables
Manipulate condition variables in a multithreaded application.

API Reference

group `condvar_apis`

Defines

`K_CONDVAR_DEFINE`(name)

Statically define and initialize a condition variable.

The condition variable can be accessed outside the module where it is defined using:

```
extern struct k_condvar <name>;
```

Parameters

- `name` – Name of the condition variable.

Functions

int `k_condvar_init`(struct k_condvar *condvar)

Initialize a condition variable.

Parameters

- `condvar` – pointer to a `k_condvar` structure

Return values

`0` – Condition variable created successfully

int `k_condvar_signal`(struct k_condvar *condvar)

Signals one thread that is pending on the condition variable.

Parameters

- `condvar` – pointer to a `k_condvar` structure

Return values

`0` – On success

int **k_condvar_broadcast**(struct k_condvar *condvar)

Unblock all threads that are pending on the condition variable.

Parameters

- **condvar** – pointer to a k_condvar structure

Returns

An integer with number of woken threads on success

int **k_condvar_wait**(struct k_condvar *condvar, struct *k_mutex* *mutex, *k_timeout_t* timeout)

Waits on the condition variable releasing the mutex lock.

Atomically releases the currently owned mutex, blocks the current thread waiting on the condition variable specified by *condvar*, and finally acquires the mutex again.

The waiting thread unblocks only after another thread calls k_condvar_signal, or k_condvar_broadcast with the same condition variable.

Parameters

- **condvar** – pointer to a k_condvar structure
- **mutex** – Address of the mutex.
- **timeout** – Waiting period for the condition variable or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- **0** – On success
- **-EAGAIN** – Waiting period timed out.

Events

An *event object* is a kernel object that implements traditional events.

- *Concepts*
- *Implementation*
  - *Defining an Event Object*
  - *Setting Events*
  - *Posting Events*
  - *Waiting for Events*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of event objects can be defined (limited only by available RAM). Each event object is referenced by its memory address. One or more threads may wait on an event object until the desired set of events has been delivered to the event object. When new events are delivered to the event object, all threads whose wait conditions have been satisfied become ready simultaneously.

An event object has the following key properties:

- A 32-bit value that tracks which events have been delivered to it.

An event object must be initialized before it can be used.

Events may be **delivered** by a thread or an ISR. When delivering events, the events may either overwrite the existing set of events or add to them in a bitwise fashion. When overwriting the existing set of events, this is referred to as setting. When adding to them in a bitwise fashion, this is referred to as posting. Both posting and setting events have the potential to fulfill match conditions of multiple threads waiting on the event object. All threads whose match conditions have been met are made active at the same time.

Threads may wait on one or more events. They may either wait for all of the requested events, or for any of them. Furthermore, threads making a wait request have the option of resetting the current set of events tracked by the event object prior to waiting. Care must be taken with this option when multiple threads wait on the same event object.

Note

The kernel does allow an ISR to query an event object, however the ISR must not attempt to wait for the events.

Implementation

Defining an Event Object An event object is defined using a variable of type *k_event*. It must then be initialized by calling *k_event_init()*.

The following code defines an event object.

```
struct k_event my_event;

k_event_init(&my_event);
```

Alternatively, an event object can be defined and initialized at compile time by calling *K_EVENT_DEFINE*.

The following code has the same effect as the code segment above.

```
K_EVENT_DEFINE(my_event);
```

Setting Events Events in an event object are set by calling *k_event_set()*.

The following code builds on the example above, and sets the events tracked by the event object to 0x001.

```
void input_available_interrupt_handler(void *arg)
{
    /* notify threads that data is available */

    k_event_set(&my_event, 0x001);

    ...
}
```

Posting Events Events are posted to an event object by calling *k_event_post()*.

The following code builds on the example above, and posts a set of events to the event object.

```
void input_available_interrupt_handler(void *arg)
{
    ...

    /* notify threads that more data is available */

    k_event_post(&my_event, 0x120);

    ...
}
```

Waiting for Events Threads wait for events by calling *k_event_wait()*.

The following code builds on the example above, and waits up to 50 milliseconds for any of the specified events to be posted. A warning is issued if none of the events are posted in time.

```
void consumer_thread(void)
{
    uint32_t  events;

    events = k_event_wait(&my_event, 0xFFF, false, K_MSEC(50));
    if (events == 0) {
        printk("No input devices are available!");
    } else {
        /* Access the desired input device(s) */
        ...
    }
    ...
}
```

Alternatively, the consumer thread may desire to wait for all the events before continuing.

```
void consumer_thread(void)
{
    uint32_t  events;

    events = k_event_wait_all(&my_event, 0x121, false, K_MSEC(50));
    if (events == 0) {
        printk("At least one input device is not available!");
    } else {
        /* Access the desired input devices */
        ...
    }
    ...
}
```

Suggested Uses Use events to indicate that a set of conditions have occurred.

Use events to pass small amounts of data to multiple threads at once.

Configuration Options Related configuration options:

- CONFIG_EVENTS

API Reference

group **event_apis**

Defines

K_EVENT_DEFINE(name)

Statically define and initialize an event object.

The event can be accessed outside the module where it is defined using:

```
extern struct k_event <name>;
```

Parameters

- **name** – Name of the event object.

Functions

void k_event_init(struct *k_event* *event)

Initialize an event object.

This routine initializes an event object, prior to its first use.

Parameters

- **event** – Address of the event object.

uint32_t k_event_post(struct *k_event* *event, uint32_t events)

Post one or more events to an event object.

This routine posts one or more events to an event object. All tasks waiting on the event object *event* whose waiting conditions become met by this posting immediately unpend.

Posting differs from setting in that posted events are merged together with the current set of events tracked by the event object.

Parameters

- **event** – Address of the event object
- **events** – Set of events to post to *event*

Return values

Previous – value of the events in *event*

uint32_t k_event_set(struct *k_event* *event, uint32_t events)

Set the events in an event object.

This routine sets the events stored in event object to the specified value. All tasks waiting on the event object *event* whose waiting conditions become met by this immediately unpend.

Setting differs from posting in that set events replace the current set of events tracked by the event object.

Parameters

- **event** – Address of the event object
- **events** – Set of events to set in *event*

Return values

Previous – value of the events in *event*

uint32_t **k_event_set_masked**(struct *k_event* *event, uint32_t events, uint32_t events_mask)

Set or clear the events in an event object.

This routine sets the events stored in event object to the specified value. All tasks waiting on the event object *event* whose waiting conditions become met by this immediately unpend. Unlike *k_event_set*, this routine allows specific event bits to be set and cleared as determined by the mask.

Parameters

- **event** – Address of the event object
- **events** – Set of events to set/clear in *event*
- **events_mask** – Mask to be applied to *events*

Return values

Previous – value of the events in *events_mask*

uint32_t **k_event_clear**(struct *k_event* *event, uint32_t events)

Clear the events in an event object.

This routine clears (resets) the specified events stored in an event object.

Parameters

- **event** – Address of the event object
- **events** – Set of events to clear in *event*

Return values

Previous – value of the events in *event*

uint32_t **k_event_wait**(struct *k_event* *event, uint32_t events, bool reset, *k_timeout_t* timeout)

Wait for any of the specified events.

This routine waits on event object *event* until any of the specified events have been delivered to the event object, or the maximum wait time *timeout* has expired. A thread may wait on up to 32 distinctly numbered events that are expressed as bits in a single 32-bit word.

Note

The caller must be careful when resetting if there are multiple threads waiting for the event object *event*.

Parameters

- **event** – Address of the event object
- **events** – Set of desired events on which to wait
- **reset** – If true, clear the set of events tracked by the event object before waiting. If false, do not clear the events.
- **timeout** – Waiting period for the desired set of events or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- **set** – of matching events upon success
- **0** – if matching events were not received within the specified time

uint32_t **k_event_wait_all**(struct *k_event* *event, uint32_t events, bool reset, *k_timeout_t* timeout)

Wait for all of the specified events.

This routine waits on event object *event* until all of the specified events have been delivered to the event object, or the maximum wait time *timeout* has expired. A thread may wait on up to 32 distinctly numbered events that are expressed as bits in a single 32-bit word.

> **Note**
>
> The caller must be careful when resetting if there are multiple threads waiting for the event object *event*.

Parameters

- **event** – Address of the event object
- **events** – Set of desired events on which to wait
- **reset** – If true, clear the set of events tracked by the event object before waiting. If false, do not clear the events.
- **timeout** – Waiting period for the desired set of events or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- **set** – of matching events upon success
- **0** – if matching events were not received within the specified time

static inline uint32_t **k_event_test**(struct *k_event* *event, uint32_t events_mask)

Test the events currently tracked in the event object.

Parameters

- **event** – Address of the event object
- **events_mask** – Set of desired events to test

Return values

Current – value of events in *events_mask*

struct **k_event**

#include <kernel.h> Event Structure.

Symmetric Multiprocessing

On multiprocessor architectures, Zephyr supports the use of multiple physical CPUs running Zephyr application code. This support is "symmetric" in the sense that no specific CPU is treated specially by default. Any processor is capable of running any Zephyr thread, with access to all standard Zephyr APIs supported.

No special application code needs to be written to take advantage of this feature. If there are two Zephyr application threads runnable on a supported dual processor device, they will both run simultaneously.

SMP configuration is controlled under the CONFIG_SMP kconfig variable. This must be set to "y" to enable SMP features, otherwise a uniprocessor kernel will be built. In general the platform default will have enabled this anywhere it's supported. When enabled, the number of physical CPUs available is visible at build time as CONFIG_MP_MAX_NUM_CPUS. Likewise, the default for this

will be the number of available CPUs on the platform and it is not expected that typical apps will change it. But it is legal and supported to set this to a smaller (but obviously not larger) number for special purposes (e.g. for testing, or to reserve a physical CPU for running non-Zephyr code).

Synchronization At the application level, core Zephyr IPC and synchronization primitives all behave identically under an SMP kernel. For example semaphores used to implement blocking mutual exclusion continue to be a proper application choice.

At the lowest level, however, Zephyr code has often used the *irq_lock()*/*irq_unlock()* primitives to implement fine grained critical sections using interrupt masking. These APIs continue to work via an emulation layer (see below), but the masking technique does not: the fact that your CPU will not be interrupted while you are in your critical section says nothing about whether a different CPU will be running simultaneously and be inspecting or modifying the same data!

Spinlocks SMP systems provide a more constrained *k_spin_lock()* primitive that not only masks interrupts locally, as done by *irq_lock()*, but also atomically validates that a shared lock variable has been modified before returning to the caller, "spinning" on the check if needed to wait for the other CPU to exit the lock. The default Zephyr implementation of *k_spin_lock()* and *k_spin_unlock()* is built on top of the pre-existing `atomic_` layer (itself usually implemented using compiler intrinsics), though facilities exist for architectures to define their own for performance reasons.

One important difference between IRQ locks and spinlocks is that the earlier API was naturally recursive: the lock was global, so it was legal to acquire a nested lock inside of a critical section. Spinlocks are separable: you can have many locks for separate subsystems or data structures, preventing CPUs from contending on a single global resource. But that means that spinlocks must not be used recursively. Code that holds a specific lock must not try to re-acquire it or it will deadlock (it is perfectly legal to nest **distinct** spinlocks, however). A validation layer is available to detect and report bugs like this.

When used on a uniprocessor system, the data component of the spinlock (the atomic lock variable) is unnecessary and elided. Except for the recursive semantics above, spinlocks in single-CPU contexts produce identical code to legacy IRQ locks. In fact the entirety of the Zephyr core kernel has now been ported to use spinlocks exclusively.

Legacy irq_lock() emulation For the benefit of applications written to the uniprocessor locking API, *irq_lock()* and *irq_unlock()* continue to work compatibly on SMP systems with identical semantics to their legacy versions. They are implemented as a single global spinlock, with a nesting count and the ability to be atomically reacquired on context switch into locked threads. The kernel will ensure that only one thread across all CPUs can hold the lock at any time, that it is released on context switch, and that it is re-acquired when necessary to restore the lock state when a thread is switched in. Other CPUs will spin waiting for the release to happen.

The overhead involved in this process has measurable performance impact, however. Unlike uniprocessor apps, SMP apps using *irq_lock()* are not simply invoking a very short (often ~1 instruction) interrupt masking operation. That, and the fact that the IRQ lock is global, means that code expecting to be run in an SMP context should be using the spinlock API wherever possible.

CPU Mask It is often desirable for real time applications to deliberately partition work across physical CPUs instead of relying solely on the kernel scheduler to decide on which threads to execute. Zephyr provides an API, controlled by the `CONFIG_SCHED_CPU_MASK` kconfig variable, which can associate a specific set of CPUs with each thread, indicating on which CPUs it can run.

By default, new threads can run on any CPU. Calling *k_thread_cpu_mask_disable()* with a particular CPU ID will prevent that thread from running on that CPU in the future. Likewise *k_thread_cpu_mask_enable()* will re-enable execution. There are also

k_thread_cpu_mask_clear() and *k_thread_cpu_mask_enable_all()* APIs available for convenience. For obvious reasons, these APIs are illegal if called on a runnable thread. The thread must be blocked or suspended, otherwise an -EINVAL will be returned.

Note that when this feature is enabled, the scheduler algorithm involved in doing the per-CPU mask test requires that the list be traversed in full. The kernel does not keep a per-CPU run queue. That means that the performance benefits from the CONFIG_SCHED_SCALABLE and CONFIG_SCHED_MULTIQ scheduler backends cannot be realized. CPU mask processing is available only when CONFIG_SCHED_DUMB is the selected backend. This requirement is enforced in the configuration layer.

SMP Boot Process A Zephyr SMP kernel begins boot identically to a uniprocessor kernel. Auxiliary CPUs begin in a disabled state in the architecture layer. All standard kernel initialization, including device initialization, happens on a single CPU before other CPUs are brought online.

Just before entering the application main() function, the kernel calls z_smp_init() to launch the SMP initialization process. This enumerates over the configured CPUs, calling into the architecture layer using *arch_cpu_start()* for each one. This function is passed a memory region to use as a stack on the foreign CPU (in practice it uses the area that will become that CPU's interrupt stack), the address of a local smp_init_top() callback function to run on that CPU, and a pointer to a "start flag" address which will be used as an atomic signal.

The local SMP initialization (smp_init_top()) on each CPU is then invoked by the architecture layer. Note that interrupts are still masked at this point. This routine is responsible for calling smp_timer_init() to set up any needed stat in the timer driver. On many architectures the timer is a per-CPU device and needs to be configured specially on auxiliary CPUs. Then it waits (spinning) for the atomic "start flag" to be released in the main thread, to guarantee that all SMP initialization is complete before any Zephyr application code runs, and finally calls z_swap() to transfer control to the appropriate runnable thread via the standard scheduler API.

Interprocessor Interrupts When running in multiprocessor environments, it is occasionally the case that state modified on the local CPU needs to be synchronously handled on a different processor.

One example is the Zephyr *k_thread_abort()* API, which cannot return until the thread that had been aborted is no longer runnable. If it is currently running on another CPU, that becomes difficult to implement.

Another is low power idle. It is a firm requirement on many devices that system idle be implemented using a low-power mode with as many interrupts (including periodic timer interrupts) disabled or deferred as is possible. If a CPU is in such a state, and on another CPU a thread becomes runnable, the idle CPU has no way to "wake up" to handle the newly-runnable load.

So where possible, Zephyr SMP architectures should implement an interprocessor interrupt. The current framework is very simple: the architecture provides at least a *arch_sched_broadcast_ipi()* call, which when invoked will flag an interrupt on all CPUs (except the current one, though that is allowed behavior). If the architecture supports directed IPIs (see CONFIG_ARCH_HAS_DIRECTED_IPIS), then the architecture also provides a *arch_sched_directed_ipi()* call, which when invoked will flag an interrupt on the specified CPUs. When an interrupt is flagged on the CPUs, the z_sched_ipi() function implemented in the scheduler will get invoked on those CPUs. The expectation is that these APIs will evolve over time to encompass more functionality (e.g. cross-CPU calls), and that the scheduler-specific calls here will be implemented in terms of a more general framework.

Note that not all SMP architectures will have a usable IPI mechanism (either missing, or just undocumented/unimplemented). In those cases Zephyr provides fallback behavior that is correct, but perhaps suboptimal.

Using this, *k_thread_abort()* becomes only slightly more complicated in SMP: for the case where a thread is actually running on another CPU (we can detect this atomically inside the scheduler),

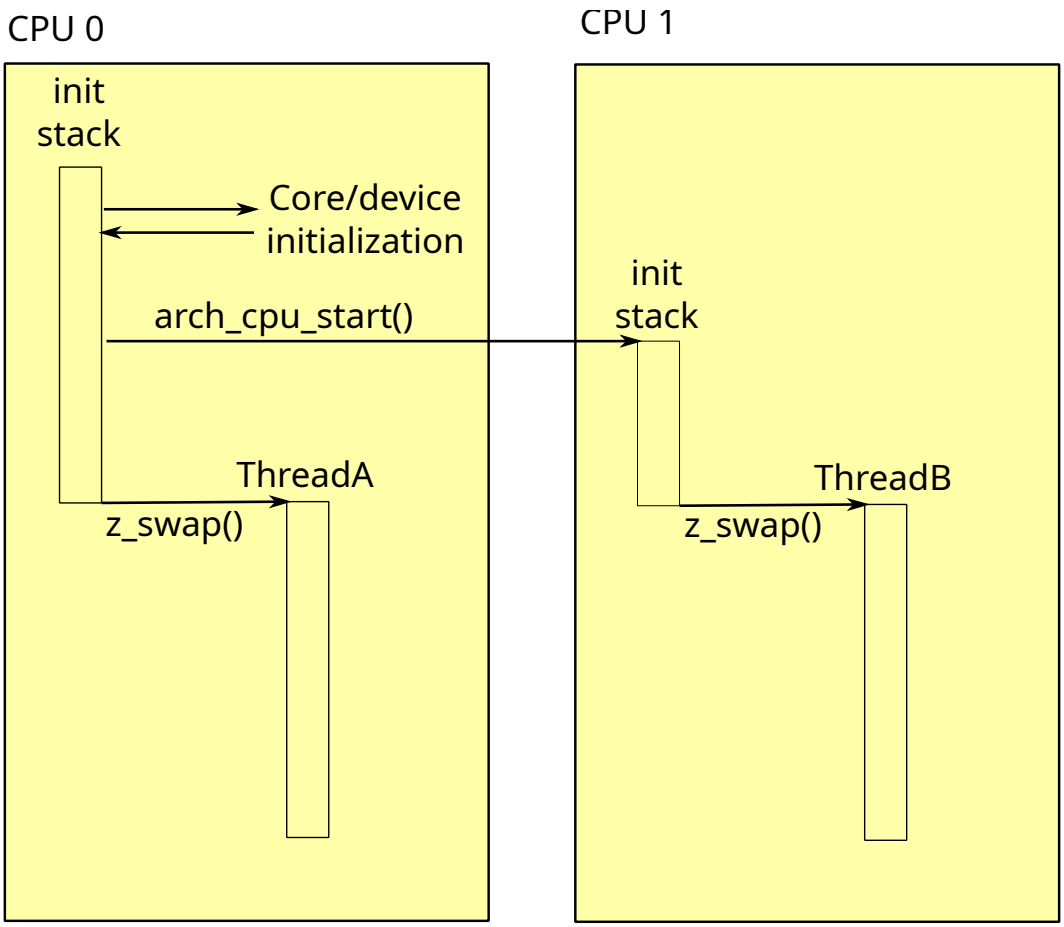

Fig. 1: Example SMP initialization process, showing a configuration with two CPUs and two app threads which begin operating simultaneously.

we broadcast an IPI and spin, waiting for the thread to either become "DEAD" or for it to re-enter the queue (in which case we terminate it the same way we would have in uniprocessor mode). Note that the "aborted" check happens on any interrupt exit, so there is no special handling needed in the IPI per se. This allows us to implement a reasonable fallback when IPI is not available: we can simply spin, waiting until the foreign CPU receives any interrupt, though this may be a much longer time!

Likewise idle wakeups are trivially implementable with an empty IPI handler. If a thread is added to an empty run queue (i.e. there may have been idle CPUs), we broadcast an IPI. A foreign CPU will then be able to see the new thread when exiting from the interrupt and will switch to it if available.

Without an IPI, however, a low power idle that requires an interrupt will not work to synchronously run new threads. The workaround in that case is more invasive: Zephyr will **not** enter the system idle handler and will instead spin in its idle loop, testing the scheduler state at high frequency (not spinning on it though, as that would involve severe lock contention) for new threads. The expectation is that power constrained SMP applications are always going to provide an IPI, and this code will only be used for testing purposes or on systems without power consumption requirements.

IPI Cascades The kernel can not control the order in which IPIs are processed by the CPUs in the system. In general, this is not an issue and a single set of IPIs is sufficient to trigger a reschedule on the N CPUs that results with them scheduling the highest N priority ready threads to execute. When CPU masking is used, there may be more than one valid set of threads (not to be confused with an optimal set of threads) that can be scheduled on the N CPUs and a single set of IPIs may be insufficient to result in any of these valid sets.

> **Note**
>
> When CPU masking is not in play, the optimal set of threads is the same as the valid set of threads. However when CPU masking is in play, there may be more than one valid set–one of which may be optimal.
>
> To better illustrate the distinction, consider a 2-CPU system with ready threads T1 and T2 at priorities 1 and 2 respectively. Let T2 be pinned to CPU0 and T1 not be pinned. If CPU0 is executing T2 and CPU1 executing T1, then this set is is both valid and optimal. However, if CPU0 is executing T1 and CPU1 is idling, then this too would be valid though not optimal.

In those cases where a single set of IPIs is not sufficient to generate a valid set, the resulting set of executing threads are expected to be close to a valid set, and subsequent IPIs can generally be expected to correct the situation soon. However, for cases where neither the approximation nor the delay are acceptable, enabling `CONFIG_SCHED_IPI_CASCADE` will allow the kernel to generate cascading IPIs until the kernel has selected a valid set of ready threads for the CPUs.

There are three types of costs/penalties associated with the IPI cascades–and for these reasons they are disabled by default. The first is a cost incurred by the CPU producing the IPI when a new thread preempts the old thread as checks must be done to compare the old thread against the threads executing on the other CPUs. The second is a cost incurred by the CPUs receiving the IPIs as they must be processed. The third is the apparent sputtering of a thread as it "winks in" and then "winks out" due to cascades stemming from the aforementioned first cost.

SMP Kernel Internals In general, Zephyr kernel code is SMP-agnostic and, like application code, will work correctly regardless of the number of CPUs available. But in a few areas there are notable changes in structure or behavior.

Per-CPU data Many elements of the core kernel data need to be implemented for each CPU in SMP mode. For example, the `_current` thread pointer obviously needs to reflect what is running locally, there are many threads running concurrently. Likewise a kernel-provided interrupt stack needs to be created and assigned for each physical CPU, as does the interrupt nesting count used to detect ISR state.

These fields are now moved into a separate struct `_cpu` instance within the `_kernel` struct, which has a `cpus[]` array indexed by ID. Compatibility fields are provided for legacy uniprocessor code trying to access the fields of `cpus[0]` using the older syntax and assembly offsets.

Note that an important requirement on the architecture layer is that the pointer to this CPU struct be available rapidly when in kernel context. The expectation is that *arch_curr_cpu()* will be implemented using a CPU-provided register or addressing mode that can store this value across arbitrary context switches or interrupts and make it available to any kernel-mode code.

Similarly, where on a uniprocessor system Zephyr could simply create a global "idle thread" at the lowest priority, in SMP we may need one for each CPU. This makes the internal predicate test for "_is_idle()" in the scheduler, which is a hot path performance environment, more complicated than simply testing the thread pointer for equality with a known static variable. In SMP mode, idle threads are distinguished by a separate field in the thread struct.

Switch-based context switching The traditional Zephyr context switch primitive has been `z_swap()`. Unfortunately, this function takes no argument specifying a thread to switch to. The expectation has always been that the scheduler has already made its preemption decision when its state was last modified and cached the resulting "next thread" pointer in a location where architecture context switch primitives can find it via a simple struct offset. That technique will not work in SMP, because the other CPU may have modified scheduler state since the current CPU last exited the scheduler (for example: it might already be running that cached thread!).

Instead, the SMP "switch to" decision needs to be made synchronously with the swap call, and as we don't want per-architecture assembly code to be handling scheduler internal state, Zephyr requires a somewhat lower-level context switch primitives for SMP systems: *arch_switch()* is always called with interrupts masked, and takes exactly two arguments. The first is an opaque (architecture defined) handle to the context to which it should switch, and the second is a pointer to such a handle into which it should store the handle resulting from the thread that is being switched out. The kernel then implements a portable `z_swap()` implementation on top of this primitive which includes the relevant scheduler logic in a location where the architecture doesn't need to understand it.

Similarly, on interrupt exit, switch-based architectures are expected to call `z_get_next_switch_handle()` to retrieve the next thread to run from the scheduler. The argument to `z_get_next_switch_handle()` is either the interrupted thread's "handle" reflecting the same opaque type used by *arch_switch()*, or NULL if that thread cannot be released to the scheduler just yet. The choice between a handle value or NULL depends on the way CPU interrupt mode is implemented.

Architectures with a large CPU register file would typically preserve only the caller-saved registers on the current thread's stack when interrupted in order to minimize interrupt latency, and preserve the callee-saved registers only when *arch_switch()* is called to minimize context switching latency. Such architectures must use NULL as the argument to `z_get_next_switch_handle()` to determine if there is a new thread to schedule, and follow through with their own *arch_switch()* or derivative if so, or directly leave interrupt mode otherwise. In the former case it is up to that switch code to store the handle resulting from the thread that is being switched out in that thread's "switch_handle" field after its context has fully been saved.

Architectures whose entry in interrupt mode already preserves the entire thread state may pass that thread's handle directly to `z_get_next_switch_handle()` and be done in one step.

Note that while SMP requires `CONFIG_USE_SWITCH`, the reverse is not true. A uniprocessor architecture built with `CONFIG_SMP` set to No might still decide to implement its context switching

using *arch_switch()*.

API Reference

group **spinlock_apis**

Spinlock APIs.

Defines

`K_SPINLOCK_BREAK`

Leaves a code block guarded with *K_SPINLOCK* after releasing the lock.

See *K_SPINLOCK* for details.

`K_SPINLOCK`(lck)

Guards a code block with the given spinlock, automatically acquiring the lock before executing the code block.

The lock will be released either when reaching the end of the code block or when leaving the block with *K_SPINLOCK_BREAK*.

Example usage:

```
K_SPINLOCK(&mylock) {

  ...execute statements with the lock held...

  if (some_condition) {
    ...release the lock and leave the guarded section prematurely:
    K_SPINLOCK_BREAK;
  }

  ...execute statements with the lock held...

}
```

Behind the scenes this pattern expands to a for-loop whose body is executed exactly once:

```
for (k_spinlock_key_t key = k_spin_lock(&mylock); ...; k_spin_unlock(&mylock,␣
↪key)) {
    ...
}
```

Note

In user mode the spinlock must be placed in memory accessible to the application, see K_APP_DMEM and K_APP_BMEM macros for details.

Warning

The code block must execute to its end or be left by calling *K_SPINLOCK_BREAK*. Otherwise, e.g. if exiting the block with a break, goto or return statement, the spinlock will not be released on exit.

Parameters

- `lck` – Spinlock used to guard the enclosed code block.

Typedefs

typedef struct z_spinlock_key **k_spinlock_key_t**

Spinlock key type.

This type defines a "key" value used by a spinlock implementation to store the system interrupt state at the time of a call to *k_spin_lock()*. It is expected to be passed to a matching *k_spin_unlock()*.

This type is opaque and should not be inspected by application code.

Functions

ALWAYS_INLINE static *k_spinlock_key_t* **k_spin_lock**(struct *k_spinlock* *l)

Lock a spinlock.

This routine locks the specified spinlock, returning a key handle representing interrupt state needed at unlock time. Upon returning, the calling thread is guaranteed not to be suspended or interrupted on its current CPU until it calls *k_spin_unlock()*. The implementation guarantees mutual exclusion: exactly one thread on one CPU will return from *k_spin_lock()* at a time. Other CPUs trying to acquire a lock already held by another CPU will enter an implementation-defined busy loop ("spinning") until the lock is released.

Separate spin locks may be nested. It is legal to lock an (unlocked) spin lock while holding a different lock. Spin locks are not recursive, however: an attempt to acquire a spin lock that the CPU already holds will deadlock.

In circumstances where only one CPU exists, the behavior of *k_spin_lock()* remains as specified above, though obviously no spinning will take place. Implementations may be free to optimize in uniprocessor contexts such that the locking reduces to an interrupt mask operation.

Parameters

- `l` – A pointer to the spinlock to lock

Returns

A key value that must be passed to *k_spin_unlock()* when the lock is released.

ALWAYS_INLINE static int **k_spin_trylock**(struct *k_spinlock* *l, *k_spinlock_key_t* *k)

Attempt to lock a spinlock.

This routine makes one attempt to lock `l`. If it is successful, then it will store the key into `k`.

See also

k_spin_lock

See also

k_spin_unlock

Parameters

- `l` – **[in]** A pointer to the spinlock to lock
- `k` – **[out]** A pointer to the spinlock key

Return values

- `0` – on success
- `-EBUSY` – if another thread holds the lock

ALWAYS_INLINE static void **k_spin_unlock**(struct *k_spinlock* *l, *k_spinlock_key_t* key)

Unlock a spin lock.

This releases a lock acquired by *k_spin_lock()*. After this function is called, any CPU will be able to acquire the lock. If other CPUs are currently spinning inside *k_spin_lock()* waiting for this lock, exactly one of them will return synchronously with the lock held.

Spin locks must be properly nested. A call to *k_spin_unlock()* must be made on the lock object most recently locked using *k_spin_lock()*, using the key value that it returned. Attempts to unlock mis-nested locks, or to unlock locks that are not held, or to passing a key parameter other than the one returned from *k_spin_lock()*, are illegal. When CONFIG_SPIN_VALIDATE is set, some of these errors can be detected by the framework.

Parameters

- `l` – A pointer to the spinlock to release
- `key` – The value returned from *k_spin_lock()* when this lock was acquired

struct **k_spinlock**

#include <*spinlock.h*> Kernel Spin Lock.

This struct defines a spin lock record on which CPUs can wait with *k_spin_lock()*. Any number of spinlocks may be defined in application code.

3.1.2 Data Passing

These pages cover kernel objects which can be used to pass data between threads and ISRs.

The following table summarizes their high-level features.

Object	Bidirectional?	Data structure	Data item size	Data Alignment	ISRs can receive?	ISRs can send?	Overrun handling
FIFO	No	Queue	Arbitrary [1]	4 B [2]	Yes [3]	Yes	N/A
LIFO	No	Queue	Arbitrary [1]	4 B [2]	Yes [3]	Yes	N/A
Stack	No	Array	Word	Word	Yes [3]	Yes	Undefined behavior
Message queue	No	Ring buffer	Arbitrary [6]	Power of two	Yes [3]	Yes	Pend thread or return -errno
Mailbox	Yes	Queue	Arbitrary [1]	Arbitrary	No	No	N/A
Pipe	No	Ring buffer [4]	Arbitrary	Arbitrary	Yes [5]	Yes [5]	Pend thread or return -errno

[1] Callers allocate space for queue overhead in the data elements themselves.

[2] Objects added with k_fifo_alloc_put() and k_lifo_alloc_put() do not have alignment constraints, but use temporary memory from the calling thread's resource pool.

[3] ISRs can receive only when passing K_NO_WAIT as the timeout argument.

[4] Optional.

[5] ISRS can send and/or receive only when passing K_NO_WAIT as the timeout argument.

[6] Data item size must be a multiple of the data alignment.

Queues

A Queue in Zephyr is a kernel object that implements a traditional queue, allowing threads and ISRs to add and remove data items of any size. The queue is similar to a FIFO and serves as the underlying implementation for both *k_fifo* and *k_lifo*. For more information on usage see *k_fifo*.

Configuration Options Related configuration options:

- None

API Reference

group `queue_apis`

Defines

`K_QUEUE_DEFINE`(name)

Statically define and initialize a queue.

The queue can be accessed outside the module where it is defined using:

```
extern struct k_queue <name>;
```

Parameters

- **name** – Name of the queue.

Functions

void **k_queue_init**(struct k_queue *queue)

Initialize a queue.

This routine initializes a queue object, prior to its first use.

Parameters

- **queue** – Address of the queue.

void **k_queue_cancel_wait**(struct k_queue *queue)

Cancel waiting on a queue.

This routine causes first thread pending on *queue*, if any, to return from *k_queue_get()* call with NULL value (as if timeout expired). If the queue is being waited on by *k_poll()*, it will return with -EINTR and K_POLL_STATE_CANCELLED state (and per above, subsequent *k_queue_get()* will return NULL).

Function properties (list may not be complete)

isr-ok

Parameters

- **queue** – Address of the queue.

void **k_queue_append**(struct k_queue *queue, void *data)

Append an element to the end of a queue.

This routine appends a data item to *queue*. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

Function properties (list may not be complete)

isr-ok

Parameters

- **queue** – Address of the queue.
- **data** – Address of the data item.

int32_t **k_queue_alloc_append**(struct k_queue *queue, void *data)

Append an element to a queue.

This routine appends a data item to *queue*. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.

Function properties (list may not be complete)

isr-ok

Parameters

- `queue` – Address of the queue.
- `data` – Address of the data item.

Return values

- `0` – on success
- `-ENOMEM` – if there isn't sufficient RAM in the caller's resource pool

void `k_queue_prepend`(struct k_queue *queue, void *data)

Prepend an element to a queue.

This routine prepends a data item to *queue*. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

Function properties (list may not be complete)

isr-ok

Parameters

- `queue` – Address of the queue.
- `data` – Address of the data item.

int32_t `k_queue_alloc_prepend`(struct k_queue *queue, void *data)

Prepend an element to a queue.

This routine prepends a data item to *queue*. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.

Function properties (list may not be complete)

isr-ok

Parameters

- `queue` – Address of the queue.
- `data` – Address of the data item.

Return values

- `0` – on success
- `-ENOMEM` – if there isn't sufficient RAM in the caller's resource pool

void `k_queue_insert`(struct k_queue *queue, void *prev, void *data)

Inserts an element to a queue.

This routine inserts a data item to *queue* after previous item. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

Function properties (list may not be complete)

isr-ok

Parameters

- `queue` – Address of the queue.
- `prev` – Address of the previous data item.
- `data` – Address of the data item.

int `k_queue_append_list`(struct k_queue *queue, void *head, void *tail)

Atomically append a list of elements to a queue.

This routine adds a list of data items to *queue* in one operation. The data items must be in a singly-linked list, with the first word in each data item pointing to the next data item; the list must be NULL-terminated.

Function properties (list may not be complete)

isr-ok

Parameters

- `queue` – Address of the queue.
- `head` – Pointer to first node in singly-linked list.
- `tail` – Pointer to last node in singly-linked list.

Return values

- `0` – on success
- `-EINVAL` – on invalid supplied data

int `k_queue_merge_slist`(struct k_queue *queue, *sys_slist_t* *list)

Atomically add a list of elements to a queue.

This routine adds a list of data items to *queue* in one operation. The data items must be in a singly-linked list implemented using a sys_slist_t object. Upon completion, the original list is empty.

Function properties (list may not be complete)

isr-ok

Parameters

- `queue` – Address of the queue.
- `list` – Pointer to sys_slist_t object.

Return values

- `0` – on success
- `-EINVAL` – on invalid data

void *`k_queue_get`(struct k_queue *queue, *k_timeout_t* timeout)

Get an element from a queue.

This routine removes first data item from *queue*. The first word of the data item is reserved for the kernel's use.

Function properties (list may not be complete)

isr-ok

Note

timeout must be set to K_NO_WAIT if called from ISR.

Parameters

- **queue** – Address of the queue.
- **timeout** – Waiting period to obtain a data item, or one of the special values K_NO_WAIT and K_FOREVER.

Returns

Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

bool **k_queue_remove**(struct k_queue *queue, void *data)

Remove an element from a queue.

This routine removes data item from *queue*. The first word of the data item is reserved for the kernel's use. Removing elements from k_queue rely on sys_slist_find_and_remove which is not a constant time operation.

Function properties (list may not be complete)

isr-ok

Note

timeout must be set to K_NO_WAIT if called from ISR.

Parameters

- **queue** – Address of the queue.
- **data** – Address of the data item.

Returns

true if data item was removed

bool **k_queue_unique_append**(struct k_queue *queue, void *data)

Append an element to a queue only if it's not present already.

This routine appends data item to *queue*. The first word of the data item is reserved for the kernel's use. Appending elements to k_queue relies on sys_slist_is_node_in_list which is not a constant time operation.

Function properties (list may not be complete)

isr-ok

Parameters

- **queue** – Address of the queue.
- **data** – Address of the data item.

Returns

true if data item was added, false if not

int k_queue_is_empty(struct k_queue *queue)

Query a queue to see if it has data available.

Note that the data might be already gone by the time this function returns if other threads are also trying to read from the queue.

Function properties (list may not be complete)

isr-ok

Parameters

- queue – Address of the queue.

Returns

Non-zero if the queue is empty.

Returns

0 if data is available.

void *k_queue_peek_head(struct k_queue *queue)

Peek element at the head of queue.

Return element from the head of queue without removing it.

Parameters

- queue – Address of the queue.

Returns

Head element, or NULL if queue is empty.

void *k_queue_peek_tail(struct k_queue *queue)

Peek element at the tail of queue.

Return element from the tail of queue without removing it.

Parameters

- queue – Address of the queue.

Returns

Tail element, or NULL if queue is empty.

FIFOs

A *FIFO* is a kernel object that implements a traditional first in, first out (FIFO) queue, allowing threads and ISRs to add and remove data items of any size.

- *Concepts*
- *Implementation*
  - *Defining a FIFO*
  - *Writing to a FIFO*
  - *Reading from a FIFO*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of FIFOs can be defined (limited only by available RAM). Each FIFO is referenced by its memory address.

A FIFO has the following key properties:

- A **queue** of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A FIFO must be initialized before it can be used. This sets its queue to empty.

FIFO data items must be aligned on a word boundary, as the kernel reserves the first word of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes of application data requires N+4 (or N+8) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with *k_fifo_alloc_put()*, instead additional memory is temporarily allocated from the calling thread's resource pool.

Note

FIFO data items are restricted to single active instance across all FIFO data queues. Any attempt to re-add a FIFO data item to a queue before it has been removed from the queue to which it was previously added will result in undefined behavior.

A data item may be **added** to a FIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the FIFO's queue. There is no limit to the number of items that may be queued.

A data item may be **removed** from a FIFO by a thread. If the FIFO's queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty FIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note

The kernel does allow an ISR to remove an item from a FIFO, however the ISR must not attempt to wait if the FIFO is empty.

If desired, **multiple data items** can be added to a FIFO in a single operation if they are chained together into a singly-linked list. This capability can be useful if multiple writers are adding sets of related data items to the FIFO, as it ensures the data items in each set are not interleaved with other data items. Adding multiple data items to a FIFO is also more efficient than adding them one at a time, and can be used to guarantee that anyone who removes the first data item in a set will be able to remove the remaining data items without waiting.

Implementation

Defining a FIFO A FIFO is defined using a variable of type `k_fifo`. It must then be initialized by calling *k_fifo_init()*.

The following code defines and initializes an empty FIFO.

```
struct k_fifo my_fifo;

k_fifo_init(&my_fifo);
```

Alternatively, an empty FIFO can be defined and initialized at compile time by calling *K_FIFO_DEFINE*.

The following code has the same effect as the code segment above.

```
K_FIFO_DEFINE(my_fifo);
```

Writing to a FIFO A data item is added to a FIFO by calling *k_fifo_put()*.

The following code builds on the example above, and uses the FIFO to send data to one or more consumer threads.

```
struct data_item_t {
    void *fifo_reserved;   /* 1st word reserved for use by FIFO */
    ...
};

struct data_item_t tx_data;

void producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...

        /* send data to consumers */
        k_fifo_put(&my_fifo, &tx_data);

        ...
    }
}
```

Additionally, a singly-linked list of data items can be added to a FIFO by calling *k_fifo_put_list()* or *k_fifo_put_slist()*.

Finally, a data item can be added to a FIFO with *k_fifo_alloc_put()*. With this API, there is no need to reserve space for the kernel's use in the data item, instead additional memory will be allocated from the calling thread's resource pool until the item is read.

Reading from a FIFO A data item is removed from a FIFO by calling *k_fifo_get()*.

The following code builds on the example above, and uses the FIFO to obtain data items from a producer thread, which are then processed in some manner.

```
void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t  *rx_data;

    while (1) {
        rx_data = k_fifo_get(&my_fifo, K_FOREVER);

        /* process FIFO data item */
        ...
    }
}
```

Suggested Uses Use a FIFO to asynchronously transfer data items of arbitrary size in a "first in, first out" manner.

Configuration Options Related configuration options:

- None

API Reference

group `fifo_apis`

Defines

`k_fifo_init`(fifo)

Initialize a FIFO queue.

This routine initializes a FIFO queue, prior to its first use.

Parameters

- `fifo` – Address of the FIFO queue.

`k_fifo_cancel_wait`(fifo)

Cancel waiting on a FIFO queue.

This routine causes first thread pending on *fifo*, if any, to return from *k_fifo_get()* call with NULL value (as if timeout expired).

Function properties (list may not be complete)

isr-ok

Parameters

- `fifo` – Address of the FIFO queue.

`k_fifo_put`(fifo, data)

Add an element to a FIFO queue.

This routine adds a data item to *fifo*. A FIFO data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

Function properties (list may not be complete)

isr-ok

Parameters

- `fifo` – Address of the FIFO.
- `data` – Address of the data item.

`k_fifo_alloc_put`(fifo, data)

Add an element to a FIFO queue.

This routine adds a data item to *fifo*. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.

Function properties (list may not be complete)

isr-ok

Parameters

- `fifo` – Address of the FIFO.
- `data` – Address of the data item.

Return values

- `0` – on success
- `-ENOMEM` – if there isn't sufficient RAM in the caller's resource pool

`k_fifo_put_list`(fifo, head, tail)

Atomically add a list of elements to a FIFO.

This routine adds a list of data items to *fifo* in one operation. The data items must be in a singly-linked list, with the first word of each data item pointing to the next data item; the list must be NULL-terminated.

Function properties (list may not be complete)

isr-ok

Parameters

- `fifo` – Address of the FIFO queue.
- `head` – Pointer to first node in singly-linked list.
- `tail` – Pointer to last node in singly-linked list.

`k_fifo_put_slist`(fifo, list)

Atomically add a list of elements to a FIFO queue.

This routine adds a list of data items to *fifo* in one operation. The data items must be in a singly-linked list implemented using a sys_slist_t object. Upon completion, the sys_slist_t object is invalid and must be re-initialized via *sys_slist_init()*.

Function properties (list may not be complete)

isr-ok

Parameters

- `fifo` – Address of the FIFO queue.
- `list` – Pointer to sys_slist_t object.

`k_fifo_get`(fifo, timeout)

Get an element from a FIFO queue.

This routine removes a data item from *fifo* in a "first in, first out" manner. The first word of the data item is reserved for the kernel's use.

Function properties (list may not be complete)

isr-ok

Note

timeout must be set to K_NO_WAIT if called from ISR.

Parameters

- `fifo` – Address of the FIFO queue.
- `timeout` – Waiting period to obtain a data item, or one of the special values K_NO_WAIT and K_FOREVER.

Returns
Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

`k_fifo_is_empty`(fifo)

Query a FIFO queue to see if it has data available.

Note that the data might be already gone by the time this function returns if other threads is also trying to read from the FIFO.

Function properties (list may not be complete)
isr-ok

Parameters

- `fifo` – Address of the FIFO queue.

Returns
Non-zero if the FIFO queue is empty.

Returns
0 if data is available.

`k_fifo_peek_head`(fifo)

Peek element at the head of a FIFO queue.

Return element from the head of FIFO queue without removing it. A usecase for this is if elements of the FIFO object are themselves containers. Then on each iteration of processing, a head container will be peeked, and some data processed out of it, and only if the container is empty, it will be completely remove from the FIFO queue.

Parameters

- `fifo` – Address of the FIFO queue.

Returns
Head element, or NULL if the FIFO queue is empty.

`k_fifo_peek_tail`(fifo)

Peek element at the tail of FIFO queue.

Return element from the tail of FIFO queue (without removing it). A usecase for this is if elements of the FIFO queue are themselves containers. Then it may be useful to add more data to the last container in a FIFO queue.

Parameters

- `fifo` – Address of the FIFO queue.

Returns
Tail element, or NULL if a FIFO queue is empty.

`K_FIFO_DEFINE`(name)

Statically define and initialize a FIFO queue.

The FIFO queue can be accessed outside the module where it is defined using:

```
extern struct k_fifo <name>;
```

Parameters

- `name` – Name of the FIFO queue.

LIFOs

A *LIFO* is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove data items of any size.

- *Concepts*
- *Implementation*
  - *Defining a LIFO*
  - *Writing to a LIFO*
  - *Reading from a LIFO*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of LIFOs can be defined (limited only by available RAM). Each LIFO is referenced by its memory address.

A LIFO has the following key properties:

- A **queue** of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A LIFO must be initialized before it can be used. This sets its queue to empty.

LIFO data items must be aligned on a word boundary, as the kernel reserves the first word of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes of application data requires N+4 (or N+8) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_lifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread's resource pool.

Note

LIFO data items are restricted to single active instance across all LIFO data queues. Any attempt to re-add a LIFO data item to a queue before it has been removed from the queue to which it was previously added will result in undefined behavior.

A data item may be **added** to a LIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the LIFO's queue. There is no limit to the number of items that may be queued.

A data item may be **removed** from a LIFO by a thread. If the LIFO's queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty LIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note

The kernel does allow an ISR to remove an item from a LIFO, however the ISR must not attempt to wait if the LIFO is empty.

Implementation

Defining a LIFO A LIFO is defined using a variable of type `k_lifo`. It must then be initialized by calling *k_lifo_init()*.

The following defines and initializes an empty LIFO.

```
struct k_lifo my_lifo;

k_lifo_init(&my_lifo);
```

Alternatively, an empty LIFO can be defined and initialized at compile time by calling *K_LIFO_DEFINE*.

The following code has the same effect as the code segment above.

```
K_LIFO_DEFINE(my_lifo);
```

Writing to a LIFO A data item is added to a LIFO by calling *k_lifo_put()*.

The following code builds on the example above, and uses the LIFO to send data to one or more consumer threads.

```
struct data_item_t {
    void *LIFO_reserved;   /* 1st word reserved for use by LIFO */
    ...
};

struct data_item_t tx data;

void producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...

        /* send data to consumers */
        k_lifo_put(&my_lifo, &tx_data);

        ...
    }
}
```

A data item can be added to a LIFO with *k_lifo_alloc_put()*. With this API, there is no need to reserve space for the kernel's use in the data item, instead additional memory will be allocated from the calling thread's resource pool until the item is read.

Reading from a LIFO A data item is removed from a LIFO by calling *k_lifo_get()*.

The following code builds on the example above, and uses the LIFO to obtain data items from a producer thread, which are then processed in some manner.

```
void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t  *rx_data;

    while (1) {
        rx_data = k_lifo_get(&my_lifo, K_FOREVER);

        /* process LIFO data item */
```

(continues on next page)

(continued from previous page)

```
        ...
    }
}
```

Suggested Uses Use a LIFO to asynchronously transfer data items of arbitrary size in a "last in, first out" manner.

Configuration Options Related configuration options:

- None.

API Reference

group `lifo_apis`

Defines

`k_lifo_init`(lifo)

Initialize a LIFO queue.

This routine initializes a LIFO queue object, prior to its first use.

Parameters

- `lifo` – Address of the LIFO queue.

`k_lifo_put`(lifo, data)

Add an element to a LIFO queue.

This routine adds a data item to *lifo*. A LIFO queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

Function properties (list may not be complete)

isr-ok

Parameters

- `lifo` – Address of the LIFO queue.
- `data` – Address of the data item.

`k_lifo_alloc_put`(lifo, data)

Add an element to a LIFO queue.

This routine adds a data item to *lifo*. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.

Function properties (list may not be complete)

isr-ok

Parameters

- `lifo` – Address of the LIFO.

- `data` – Address of the data item.

Return values

- `0` – on success
- `-ENOMEM` – if there isn't sufficient RAM in the caller's resource pool

`k_lifo_get`(lifo, timeout)

Get an element from a LIFO queue.

This routine removes a data item from *LIFO* in a "last in, first out" manner. The first word of the data item is reserved for the kernel's use.

Function properties (list may not be complete)

isr-ok

> **Note**
>
> *timeout* must be set to K_NO_WAIT if called from ISR.

Parameters

- `lifo` – Address of the LIFO queue.
- `timeout` – Waiting period to obtain a data item, or one of the special values K_NO_WAIT and K_FOREVER.

Returns

Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

`K_LIFO_DEFINE`(name)

Statically define and initialize a LIFO queue.

The LIFO queue can be accessed outside the module where it is defined using:

```
extern struct k_lifo <name>;
```

Parameters

- `name` – Name of the fifo.

Stacks

A *stack* is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove a limited number of integer data values.

- *Concepts*
- *Implementation*
  - *Defining a Stack*
  - *Pushing to a Stack*
  - *Popping from a Stack*
- *Suggested Uses*

- *Configuration Options*
- *API Reference*

Concepts Any number of stacks can be defined (limited only by available RAM). Each stack is referenced by its memory address.

A stack has the following key properties:

- A **queue** of integer data values that have been added but not yet removed. The queue is implemented using an array of stack_data_t values and must be aligned on a native word boundary. The stack_data_t type corresponds to the native word size i.e. 32 bits or 64 bits depending on the CPU architecture and compilation mode.
- A **maximum quantity** of data values that can be queued in the array.

A stack must be initialized before it can be used. This sets its queue to empty.

A data value can be **added** to a stack by a thread or an ISR. The value is given directly to a waiting thread, if one exists; otherwise the value is added to the LIFO's queue.

Note

If `CONFIG_NO_RUNTIME_CHECKS` is enabled, the kernel will *not* detect and prevent attempts to add a data value to a stack that has already reached its maximum quantity of queued values. Adding a data value to a stack that is already full will result in array overflow, and lead to unpredictable behavior.

A data value may be **removed** from a stack by a thread. If the stack's queue is empty a thread may choose to wait for it to be given. Any number of threads may wait on an empty stack simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note

The kernel does allow an ISR to remove an item from a stack, however the ISR must not attempt to wait if the stack is empty.

Implementation

Defining a Stack A stack is defined using a variable of type `k_stack`. It must then be initialized by calling *`k_stack_init()`* or *`k_stack_alloc_init()`*. In the latter case, a buffer is not provided and it is instead allocated from the calling thread's resource pool.

The following code defines and initializes an empty stack capable of holding up to ten word-sized data values.

```
#define MAX_ITEMS 10

stack_data_t my_stack_array[MAX_ITEMS];
struct k_stack my_stack;

k_stack_init(&my_stack, my_stack_array, MAX_ITEMS);
```

Alternatively, a stack can be defined and initialized at compile time by calling *K_STACK_DEFINE*.

The following code has the same effect as the code segment above. Observe that the macro defines both the stack and its array of data values.

```
K_STACK_DEFINE(my_stack, MAX_ITEMS);
```

Pushing to a Stack A data item is added to a stack by calling *k_stack_push()*.

The following code builds on the example above, and shows how a thread can create a pool of data structures by saving their memory addresses in a stack.

```
/* define array of data structures */
struct my_buffer_type {
    int field1;
    ...
    };
struct my_buffer_type my_buffers[MAX_ITEMS];

/* save address of each data structure in a stack */
for (int i = 0; i < MAX_ITEMS; i++) {
    k_stack_push(&my_stack, (stack_data_t)&my_buffers[i]);
}
```

Popping from a Stack A data item is taken from a stack by calling *k_stack_pop()*.

The following code builds on the example above, and shows how a thread can dynamically allocate an unused data structure. When the data structure is no longer required, the thread must push its address back on the stack to allow the data structure to be reused.

```
struct my_buffer_type *new_buffer;

k_stack_pop(&buffer_stack, (stack_data_t *)&new_buffer, K_FOREVER);
new_buffer->field1 = ...
```

Suggested Uses Use a stack to store and retrieve integer data values in a "last in, first out" manner, when the maximum number of stored items is known.

Configuration Options Related configuration options:

- None.

API Reference

group `stack_apis`

Defines

`K_STACK_DEFINE`(name, stack_num_entries)

Statically define and initialize a stack.

The stack can be accessed outside the module where it is defined using:

```
extern struct k_stack <name>;
```

Parameters

- `name` – Name of the stack.
- `stack_num_entries` – Maximum number of values that can be stacked.

Functions

void `k_stack_init`(struct k_stack *stack, stack_data_t *buffer, uint32_t num_entries)

Initialize a stack.

This routine initializes a stack object, prior to its first use.

Parameters

- `stack` – Address of the stack.
- `buffer` – Address of array used to hold stacked values.
- `num_entries` – Maximum number of values that can be stacked.

int32_t `k_stack_alloc_init`(struct k_stack *stack, uint32_t num_entries)

Initialize a stack.

This routine initializes a stack object, prior to its first use. Internal buffers will be allocated from the calling thread's resource pool. This memory will be released if *k_stack_cleanup()* is called, or userspace is enabled and the stack object loses all references to it.

Parameters

- `stack` – Address of the stack.
- `num_entries` – Maximum number of values that can be stacked.

Returns

-ENOMEM if memory couldn't be allocated

int `k_stack_cleanup`(struct k_stack *stack)

Release a stack's allocated buffer.

If a stack object was given a dynamically allocated buffer via *k_stack_alloc_init()*, this will free it. This function does nothing if the buffer wasn't dynamically allocated.

Parameters

- `stack` – Address of the stack.

Return values

- `0` – on success
- `-EAGAIN` – when object is still in use

int `k_stack_push`(struct k_stack *stack, stack_data_t data)

Push an element onto a stack.

This routine adds a stack_data_t value *data* to *stack*.

Function properties (list may not be complete)

isr-ok

Parameters

- `stack` – Address of the stack.
- `data` – Value to push onto the stack.

Return values

- `0` – on success
- `-ENOMEM` – if stack is full

int `k_stack_pop`(struct k_stack *stack, stack_data_t *data, *k_timeout_t* timeout)

Pop an element from a stack.

This routine removes a stack_data_t value from *stack* in a "last in,

first out" manner and stores the value in *data*.

Function properties (list may not be complete)

isr-ok

> **Note**
>
> *timeout* must be set to K_NO_WAIT if called from ISR.

Parameters

- `stack` – Address of the stack.
- `data` – Address of area to hold the value popped from the stack.
- `timeout` – Waiting period to obtain a value, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- `0` – Element popped from stack.
- `-EBUSY` – Returned without waiting.
- `-EAGAIN` – Waiting period timed out.

Message Queues

A *message queue* is a kernel object that implements a simple message queue, allowing threads and ISRs to asynchronously send and receive fixed-size data items.

- *Concepts*
- *Implementation*
  - *Defining a Message Queue*
  - *Writing to a Message Queue*
  - *Reading from a Message Queue*
  - *Peeking into a Message Queue*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of message queues can be defined (limited only by available RAM). Each message queue is referenced by its memory address.

A message queue has the following key properties:

- A **ring buffer** of data items that have been sent but not yet received.
- A **data item size**, measured in bytes.
- A **maximum quantity** of data items that can be queued in the ring buffer.

A message queue must be initialized before it can be used. This sets its ring buffer to empty.

A data item can be **sent** to a message queue by a thread or an ISR. The data item pointed at by the sending thread is copied to a waiting thread, if one exists; otherwise the item is copied to the message queue's ring buffer, if space is available. In either case, the size of the data area being sent *must* equal the message queue's data item size.

If a thread attempts to send a data item when the ring buffer is full, the sending thread may choose to wait for space to become available. Any number of sending threads may wait simultaneously when the ring buffer is full; when space becomes available it is given to the highest priority sending thread that has waited the longest.

A data item can be **received** from a message queue by a thread. The data item is copied to the area specified by the receiving thread; the size of the receiving area *must* equal the message queue's data item size.

If a thread attempts to receive a data item when the ring buffer is empty, the receiving thread may choose to wait for a data item to be sent. Any number of receiving threads may wait simultaneously when the ring buffer is empty; when a data item becomes available it is given to the highest priority receiving thread that has waited the longest.

A thread can also **peek** at the message on the head of a message queue without removing it from the queue. The data item is copied to the area specified by the receiving thread; the size of the receiving area *must* equal the message queue's data item size.

Note

The kernel does allow an ISR to receive an item from a message queue, however the ISR must not attempt to wait if the message queue is empty.

Note

Alignment of the message queue's ring buffer is not necessary. The underlying implementation uses `memcpy()` (which is alignment-agnostic) and does not expose any internal pointers.

Implementation

Defining a Message Queue A message queue is defined using a variable of type *k_msgq*. It must then be initialized by calling *k_msgq_init()*.

The following code defines and initializes an empty message queue that is capable of holding 10 items, each of which is 12 bytes long.

```
struct data_item_type {
    uint32_t field1;
    uint32_t field2;
    uint32_t field3;
};
```

(continues on next page)

(continued from previous page)

```
char my_msgq_buffer[10 * sizeof(struct data_item_type)];
struct k_msgq my_msgq;

k_msgq_init(&my_msgq, my_msgq_buffer, sizeof(struct data_item_type), 10);
```

Alternatively, a message queue can be defined and initialized at compile time by calling *K_MSGQ_DEFINE*.

The following code has the same effect as the code segment above. Observe that the macro defines both the message queue and its buffer.

```
K_MSGQ_DEFINE(my_msgq, sizeof(struct data_item_type), 10, 1);
```

Writing to a Message Queue A data item is added to a message queue by calling *k_msgq_put()*.

The following code builds on the example above, and uses the message queue to pass data items from a producing thread to one or more consuming threads. If the message queue fills up because the consumers can't keep up, the producing thread throws away all existing data so the newer data can be saved.

```
void producer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* create data item to send (e.g. measurement, timestamp, ...) */
        data = ...

        /* send data to consumers */
        while (k_msgq_put(&my_msgq, &data, K_NO_WAIT) != 0) {
            /* message queue is full: purge old data & try again */
            k_msgq_purge(&my_msgq);
        }

        /* data item was successfully added to message queue */
    }
}
```

Reading from a Message Queue A data item is taken from a message queue by calling *k_msgq_get()*.

The following code builds on the example above, and uses the message queue to process data items generated by one or more producing threads. Note that the return value of *k_msgq_get()* should be tested as -ENOMSG can be returned due to *k_msgq_purge()*.

```
void consumer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* get a data item */
        k_msgq_get(&my_msgq, &data, K_FOREVER);

        /* process data item */
        ...
    }
}
```

Peeking into a Message Queue A data item is read from a message queue by calling *k_msgq_peek()*.

The following code peeks into the message queue to read the data item at the head of the queue that is generated by one or more producing threads.

```
void consumer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* read a data item by peeking into the queue */
        k_msgq_peek(&my_msgq, &data);

        /* process data item */
        ...
    }
}
```

Suggested Uses Use a message queue to transfer small data items between threads in an asynchronous manner.

Note

A message queue can be used to transfer large data items, if desired. However, this can increase interrupt latency as interrupts are locked while a data item is written or read. The time to write or read a data item increases linearly with its size since the item is copied in its entirety to or from the buffer in memory. For this reason, it is usually preferable to transfer large data items by exchanging a pointer to the data item, rather than the data item itself.

A synchronous transfer can be achieved by using the kernel's mailbox object type.

Configuration Options Related configuration options:

- None.

API Reference

group `msgq_apis`

Defines

`K_MSGQ_FLAG_ALLOC`

`K_MSGQ_DEFINE`(q_name, q_msg_size, q_max_msgs, q_align)

Statically define and initialize a message queue.

The message queue's ring buffer contains space for *q_max_msgs* messages, each of which is *q_msg_size* bytes long. Alignment of the message queue's ring buffer is not necessary, setting *q_align* to 1 is sufficient.

The message queue can be accessed outside the module where it is defined using:

```
extern struct k_msgq <name>;
```

Parameters

- `q_name` – Name of the message queue.
- `q_msg_size` – Message size (in bytes).
- `q_max_msgs` – Maximum number of messages that can be queued.
- `q_align` – Alignment of the message queue's ring buffer (power of 2).

Functions

void **k_msgq_init**(struct *k_msgq* *msgq, char *buffer, size_t msg_size, uint32_t max_msgs)

Initialize a message queue.

This routine initializes a message queue object, prior to its first use.

The message queue's ring buffer must contain space for *max_msgs* messages, each of which is *msg_size* bytes long. Alignment of the message queue's ring buffer is not necessary.

Parameters

- `msgq` – Address of the message queue.
- `buffer` – Pointer to ring buffer that holds queued messages.
- `msg_size` – Message size (in bytes).
- `max_msgs` – Maximum number of messages that can be queued.

int **k_msgq_alloc_init**(struct *k_msgq* *msgq, size_t msg_size, uint32_t max_msgs)

Initialize a message queue.

This routine initializes a message queue object, prior to its first use, allocating its internal ring buffer from the calling thread's resource pool.

Memory allocated for the ring buffer can be released by calling *k_msgq_cleanup()*, or if userspace is enabled and the msgq object loses all of its references.

Parameters

- `msgq` – Address of the message queue.
- `msg_size` – Message size (in bytes).
- `max_msgs` – Maximum number of messages that can be queued.

Returns

0 on success, -ENOMEM if there was insufficient memory in the thread's resource pool, or -EINVAL if the size parameters cause an integer overflow.

int **k_msgq_cleanup**(struct *k_msgq* *msgq)

Release allocated buffer for a queue.

Releases memory allocated for the ring buffer.

Parameters

- `msgq` – message queue to cleanup

Return values

- `0` – on success
- `-EBUSY` – Queue not empty

int `k_msgq_put`(struct *k_msgq* *msgq, const void *data, *k_timeout_t* timeout)

Send a message to a message queue.

This routine sends a message to message queue *q*.

Function properties (list may not be complete)

isr-ok

> **Note**
>
> The message content is copied from *data* into *msgq* and the *data* pointer is not retained, so the message content will not be modified by this function.

Parameters

- `msgq` – Address of the message queue.
- `data` – Pointer to the message.
- `timeout` – Waiting period to add the message, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- `0` – Message sent.
- `-ENOMSG` – Returned without waiting or queue purged.
- `-EAGAIN` – Waiting period timed out.

int `k_msgq_get`(struct *k_msgq* *msgq, void *data, *k_timeout_t* timeout)

Receive a message from a message queue.

This routine receives a message from message queue *q* in a “first in,

first out” manner.

Function properties (list may not be complete)

isr-ok

> **Note**
>
> *timeout* must be set to K_NO_WAIT if called from ISR.

Parameters

- `msgq` – Address of the message queue.
- `data` – Address of area to hold the received message.
- `timeout` – Waiting period to receive the message, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- `0` – Message received.
- `-ENOMSG` – Returned without waiting.
- `-EAGAIN` – Waiting period timed out.

int k_msgq_peek(struct *k_msgq* *msgq, void *data)

Peek/read a message from a message queue.

This routine reads a message from message queue *q* in a "first in,

first out" manner and leaves the message in the queue.

Function properties (list may not be complete)

isr-ok

Parameters

- msgq – Address of the message queue.
- data – Address of area to hold the message read from the queue.

Return values

- 0 – Message read.
- -ENOMSG – Returned when the queue has no message.

int k_msgq_peek_at(struct *k_msgq* *msgq, void *data, uint32_t idx)

Peek/read a message from a message queue at the specified index.

This routine reads a message from message queue at the specified index and leaves the message in the queue. k_msgq_peek_at(msgq, data, 0) is equivalent to k_msgq_peek(msgq, data)

Function properties (list may not be complete)

isr-ok

Parameters

- msgq – Address of the message queue.
- data – Address of area to hold the message read from the queue.
- idx – Message queue index at which to peek

Return values

- 0 – Message read.
- -ENOMSG – Returned when the queue has no message at index.

void k_msgq_purge(struct *k_msgq* *msgq)

Purge a message queue.

This routine discards all unreceived messages in a message queue's ring buffer. Any threads that are blocked waiting to send a message to the message queue are unblocked and see an -ENOMSG error code.

Parameters

- msgq – Address of the message queue.

uint32_t k_msgq_num_free_get(struct *k_msgq* *msgq)

Get the amount of free space in a message queue.

This routine returns the number of unused entries in a message queue's ring buffer.

Parameters

- msgq – Address of the message queue.

Returns
Number of unused ring buffer entries.

void **k_msgq_get_attrs**(struct *k_msgq* *msgq, struct *k_msgq_attrs* *attrs)
Get basic attributes of a message queue.

This routine fetches basic attributes of message queue into attr argument.

Parameters

- **msgq** – Address of the message queue.
- **attrs** – pointer to message queue attribute structure.

uint32_t **k_msgq_num_used_get**(struct *k_msgq* *msgq)
Get the number of messages in a message queue.

This routine returns the number of messages in a message queue's ring buffer.

Parameters

- **msgq** – Address of the message queue.

Returns
Number of messages.

struct **k_msgq**
#include <*kernel.h*> Message Queue Structure.

Public Members

_wait_q_t **wait_q**
Message queue wait queue.

struct *k_spinlock* **lock**
Lock.

size_t **msg_size**
Message size.

uint32_t **max_msgs**
Maximal number of messages.

char ***buffer_start**
Start of message buffer.

char ***buffer_end**
End of message buffer.

char ***read_ptr**
Read pointer.

char ***write_ptr**
Write pointer.

uint32_t **used_msgs**
Number of used messages.

uint8_t **flags**
Message queue.

struct **k_msgq_attrs**
#include <*kernel.h*> Message Queue Attributes.

Public Members

size_t **msg_size**
Message Size.

uint32_t **max_msgs**
Maximal number of messages.

uint32_t **used_msgs**
Used messages.

Mailboxes

A *mailbox* is a kernel object that provides enhanced message queue capabilities that go beyond the capabilities of a message queue object. A mailbox allows threads to send and receive messages of any size synchronously or asynchronously.

- *Concepts*
  - *Message Format*
  - *Message Lifecycle*
  - *Thread Compatibility*
  - *Message Flow Control*
- *Implementation*
  - *Defining a Mailbox*
  - *Message Descriptors*
  - *Sending a Message*
  - *Receiving a Message*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of mailboxes can be defined (limited only by available RAM). Each mailbox is referenced by its memory address.

A mailbox has the following key properties:

- A **send queue** of messages that have been sent but not yet received.
- A **receive queue** of threads that are waiting to receive a message.

A mailbox must be initialized before it can be used. This sets both of its queues to empty.

A mailbox allows threads, but not ISRs, to exchange messages. A thread that sends a message is known as the **sending thread**, while a thread that receives the message is known as the **receiving thread**. Each message may be received by only one thread (i.e. point-to-multipoint and broadcast messaging is not supported).

Messages exchanged using a mailbox are handled non-anonymously, allowing both threads participating in an exchange to know (and even specify) the identity of the other thread.

Message Format A **message descriptor** is a data structure that specifies where a message's data is located, and how the message is to be handled by the mailbox. Both the sending thread and the receiving thread supply a message descriptor when accessing a mailbox. The mailbox uses the message descriptors to perform a message exchange between compatible sending and receiving threads. The mailbox also updates certain message descriptor fields during the exchange, allowing both threads to know what has occurred.

A mailbox message contains zero or more bytes of **message data**. The size and format of the message data is application-defined, and can vary from one message to the next.

A **message buffer** is an area of memory provided by the thread that sends or receives the message data. An array or structure variable can often be used for this purpose.

A message that has neither form of message data is called an **empty message**.

> **Note**
>
> A message whose message buffer exists, but contains zero bytes of actual data, is *not* an empty message.

Message Lifecycle The life cycle of a message is straightforward. A message is created when it is given to a mailbox by the sending thread. The message is then owned by the mailbox until it is given to a receiving thread. The receiving thread may retrieve the message data when it receives the message from the mailbox, or it may perform data retrieval during a second, subsequent mailbox operation. Only when data retrieval has occurred is the message deleted by the mailbox.

Thread Compatibility A sending thread can specify the address of the thread to which the message is sent, or send it to any thread by specifying `K_ANY`. Likewise, a receiving thread can specify the address of the thread from which it wishes to receive a message, or it can receive a message from any thread by specifying `K_ANY`. A message is exchanged only when the requirements of both the sending thread and receiving thread are satisfied; such threads are said to be **compatible**.

For example, if thread A sends a message to thread B (and only thread B) it will be received by thread B if thread B tries to receive a message from thread A or if thread B tries to receive from any thread. The exchange will not occur if thread B tries to receive a message from thread C. The message can never be received by thread C, even if it tries to receive a message from thread A (or from any thread).

Message Flow Control Mailbox messages can be exchanged **synchronously** or **asynchronously**. In a synchronous exchange, the sending thread blocks until the message has been fully processed by the receiving thread. In an asynchronous exchange, the sending thread does not wait until the message has been received by another thread before continuing; this allows the sending thread to do other work (such as gather data that will be used in the next message) *before* the message is given to a receiving thread and fully processed. The technique used for a given message exchange is determined by the sending thread.

The synchronous exchange technique provides an implicit form of flow control, preventing a sending thread from generating messages faster than they can be consumed by receiving threads. The asynchronous exchange technique provides an explicit form of flow control, which allows a sending thread to determine if a previously sent message still exists before sending a subsequent message.

Implementation

Defining a Mailbox A mailbox is defined using a variable of type *k_mbox*. It must then be initialized by calling *k_mbox_init()*.

The following code defines and initializes an empty mailbox.

```
struct k_mbox my_mailbox;

k_mbox_init(&my_mailbox);
```

Alternatively, a mailbox can be defined and initialized at compile time by calling *K_MBOX_DEFINE*.

The following code has the same effect as the code segment above.

```
K_MBOX_DEFINE(my_mailbox);
```

Message Descriptors A message descriptor is a structure of type *k_mbox_msg*. Only the fields listed below should be used; any other fields are for internal mailbox use only.

info
: A 32-bit value that is exchanged by the message sender and receiver, and whose meaning is defined by the application. This exchange is bi-directional, allowing the sender to pass a value to the receiver during any message exchange, and allowing the receiver to pass a value to the sender during a synchronous message exchange.

size
: The message data size, in bytes. Set it to zero when sending an empty message, or when sending a message buffer with no actual data. When receiving a message, set it to the maximum amount of data desired, or to zero if the message data is not wanted. The mailbox updates this field with the actual number of data bytes exchanged once the message is received.

tx_data
: A pointer to the sending thread's message buffer. Set it to `NULL` when sending an empty message. Leave this field uninitialized when receiving a message.

tx_target_thread
: The address of the desired receiving thread. Set it to `K_ANY` to allow any thread to receive the message. Leave this field uninitialized when receiving a message. The mailbox updates this field with the actual receiver's address once the message is received.

rx_source_thread
: The address of the desired sending thread. Set it to `K_ANY` to receive a message sent by any thread. Leave this field uninitialized when sending a message. The mailbox updates this field with the actual sender's address when the message is put into the mailbox.

Sending a Message A thread sends a message by first creating its message data, if any.

Next, the sending thread creates a message descriptor that characterizes the message to be sent, as described in the previous section.

Finally, the sending thread calls a mailbox send API to initiate the message exchange. The message is immediately given to a compatible receiving thread, if one is currently waiting. Otherwise, the message is added to the mailbox's send queue.

Any number of messages may exist simultaneously on a send queue. The messages in the send queue are sorted according to the priority of the sending thread. Messages of equal priority are sorted so that the oldest message can be received first.

For a synchronous send operation, the operation normally completes when a receiving thread has both received the message and retrieved the message data. If the message is not received before the waiting period specified by the sending thread is reached, the message is removed from the mailbox's send queue and the send operation fails. When a send operation completes successfully the sending thread can examine the message descriptor to determine which thread received the message, how much data was exchanged, and the application-defined info value supplied by the receiving thread.

Note

A synchronous send operation may block the sending thread indefinitely, even when the thread specifies a maximum waiting period. The waiting period only limits how long the mailbox waits before the message is received by another thread. Once a message is received there is *no* limit to the time the receiving thread may take to retrieve the message data and unblock the sending thread.

For an asynchronous send operation, the operation always completes immediately. This allows the sending thread to continue processing regardless of whether the message is given to a receiving thread immediately or added to the send queue. The sending thread may optionally specify a semaphore that the mailbox gives when the message is deleted by the mailbox, for example, when the message has been received and its data retrieved by a receiving thread. The use of a semaphore allows the sending thread to easily implement a flow control mechanism that ensures that the mailbox holds no more than an application-specified number of messages from a sending thread (or set of sending threads) at any point in time.

Note

A thread that sends a message asynchronously has no way to determine which thread received the message, how much data was exchanged, or the application-defined info value supplied by the receiving thread.

Sending an Empty Message This code uses a mailbox to synchronously pass 4 byte random values to any consuming thread that wants one. The message "info" field is large enough to carry the information being exchanged, so the data portion of the message isn't used.

```
void producer_thread(void)
{
    struct k_mbox_msg send_msg;

    while (1) {

        /* generate random value to send */
        uint32_t random_value = sys_rand32_get();
```

(continues on next page)

(continued from previous page)

```
        /* prepare to send empty message */
        send_msg.info = random_value;
        send_msg.size = 0;
        send_msg.tx_data = NULL;
        send_msg.tx_target_thread = K_ANY;

        /* send message and wait until a consumer receives it */
        k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);
    }
}
```

Sending Data Using a Message Buffer This code uses a mailbox to synchronously pass variable-sized requests from a producing thread to any consuming thread that wants it. The message "info" field is used to exchange information about the maximum size message buffer that each thread can handle.

```
void producer_thread(void)
{
    char buffer[100];
    int buffer_bytes_used;

    struct k_mbox_msg send_msg;

    while (1) {

        /* generate data to send */
        ...
        buffer_bytes_used = ... ;
        memcpy(buffer, source, buffer_bytes_used);

        /* prepare to send message */
        send_msg.info = buffer_bytes_used;
        send_msg.size = buffer_bytes_used;
        send_msg.tx_data = buffer;
        send_msg.tx_target_thread = K_ANY;

        /* send message and wait until a consumer receives it */
        k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);

        /* info, size, and tx_target_thread fields have been updated */

        /* verify that message data was fully received */
        if (send_msg.size < buffer_bytes_used) {
            printf("some message data dropped during transfer!");
            printf("receiver only had room for %d bytes", send_msg.info);
        }
    }
}
```

Receiving a Message A thread receives a message by first creating a message descriptor that characterizes the message it wants to receive. It then calls one of the mailbox receive APIs. The mailbox searches its send queue and takes the message from the first compatible thread it finds. If no compatible thread exists, the receiving thread may choose to wait for one. If no compatible thread appears before the waiting period specified by the receiving thread is reached, the receive operation fails. Once a receive operation completes successfully the receiving thread can examine the message descriptor to determine which thread sent the message, how much data was exchanged, and the application-defined info value supplied by the sending thread.

Any number of receiving threads may wait simultaneously on a mailboxes' receive queue. The threads are sorted according to their priority; threads of equal priority are sorted so that the one that started waiting first can receive a message first.

Note

Receiving threads do not always receive messages in a first in, first out (FIFO) order, due to the thread compatibility constraints specified by the message descriptors. For example, if thread A waits to receive a message only from thread X and then thread B waits to receive a message from thread Y, an incoming message from thread Y to any thread will be given to thread B and thread A will continue to wait.

The receiving thread controls both the quantity of data it retrieves from an incoming message and where the data ends up. The thread may choose to take all of the data in the message, to take only the initial part of the data, or to take no data at all. Similarly, the thread may choose to have the data copied into a message buffer of its choice.

The following sections outline various approaches a receiving thread may use when retrieving message data.

Retrieving Data at Receive Time The most straightforward way for a thread to retrieve message data is to specify a message buffer when the message is received. The thread indicates both the location of the message buffer (which must not be NULL) and its size.

The mailbox copies the message's data to the message buffer as part of the receive operation. If the message buffer is not big enough to contain all of the message's data, any uncopied data is lost. If the message is not big enough to fill all of the buffer with data, the unused portion of the message buffer is left unchanged. In all cases the mailbox updates the receiving thread's message descriptor to indicate how many data bytes were copied (if any).

The immediate data retrieval technique is best suited for small messages where the maximum size of a message is known in advance.

The following code uses a mailbox to process variable-sized requests from any producing thread, using the immediate data retrieval technique. The message "info" field is used to exchange information about the maximum size message buffer that each thread can handle.

```
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[100];

    int i;
    int total;

    while (1) {
        /* prepare to receive message */
        recv_msg.info = 100;
        recv_msg.size = 100;
        recv_msg.rx_source_thread = K_ANY;

        /* get a data item, waiting as long as needed */
        k_mbox_get(&my_mailbox, &recv_msg, buffer, K_FOREVER);

        /* info, size, and rx_source_thread fields have been updated */

        /* verify that message data was fully received */
        if (recv_msg.info != recv_msg.size) {
            printf("some message data dropped during transfer!");
            printf("sender tried to send %d bytes", recv_msg.info);
```

(continues on next page)

(continued from previous page)

```
        }

        /* compute sum of all message bytes (from 0 to 100 of them) */
        total = 0;
        for (i = 0; i < recv_msg.size; i++) {
            total += buffer[i];
        }
    }
}
```

Retrieving Data Later Using a Message Buffer A receiving thread may choose to defer message data retrieval at the time the message is received, so that it can retrieve the data into a message buffer at a later time. The thread does this by specifying a message buffer location of NULL and a size indicating the maximum amount of data it is willing to retrieve later.

The mailbox does not copy any message data as part of the receive operation. However, the mailbox still updates the receiving thread's message descriptor to indicate how many data bytes are available for retrieval.

The receiving thread must then respond as follows:

- If the message descriptor size is zero, then either the sender's message contained no data or the receiving thread did not want to receive any data. The receiving thread does not need to take any further action, since the mailbox has already completed data retrieval and deleted the message.
- If the message descriptor size is non-zero and the receiving thread still wants to retrieve the data, the thread must call *k_mbox_data_get()* and supply a message buffer large enough to hold the data. The mailbox copies the data into the message buffer and deletes the message.
- If the message descriptor size is non-zero and the receiving thread does *not* want to retrieve the data, the thread must call *k_mbox_data_get()* and specify a message buffer of NULL. The mailbox deletes the message without copying the data.

The subsequent data retrieval technique is suitable for applications where immediate retrieval of message data is undesirable. For example, it can be used when memory limitations make it impractical for the receiving thread to always supply a message buffer capable of holding the largest possible incoming message.

The following code uses a mailbox's deferred data retrieval mechanism to get message data from a producing thread only if the message meets certain criteria, thereby eliminating unneeded data copying. The message "info" field supplied by the sender is used to classify the message.

```
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[10000];

    while (1) {
        /* prepare to receive message */
        recv_msg.size = 10000;
        recv_msg.rx_source_thread = K_ANY;

        /* get message, but not its data */
        k_mbox_get(&my_mailbox, &recv_msg, NULL, K_FOREVER);

        /* get message data for only certain types of messages */
        if (is_message_type_ok(recv_msg.info)) {
            /* retrieve message data and delete the message */
            k_mbox_data_get(&recv_msg, buffer);
```

(continues on next page)

(continued from previous page)

```
            /* process data in "buffer" */
            ...
        } else {
            /* ignore message data and delete the message */
            k_mbox_data_get(&recv_msg, NULL);
        }
    }
}
```

Suggested Uses Use a mailbox to transfer data items between threads whenever the capabilities of a message queue are insufficient.

Configuration Options Related configuration options:

- CONFIG_NUM_MBOX_ASYNC_MSGS

API Reference

group mailbox_apis

Defines

K_MBOX_DEFINE(name)

Statically define and initialize a mailbox.

The mailbox is to be accessed outside the module where it is defined using:

```
extern struct k_mbox <name>;
```

Parameters

- **name** – Name of the mailbox.

Functions

void k_mbox_init(struct *k_mbox* *mbox)

Initialize a mailbox.

This routine initializes a mailbox object, prior to its first use.

Parameters

- **mbox** – Address of the mailbox.

int k_mbox_put(struct *k_mbox* *mbox, struct *k_mbox_msg* *tx_msg, *k_timeout_t* timeout)

Send a mailbox message in a synchronous manner.

This routine sends a message to *mbox* and waits for a receiver to both receive and process it. The message data may be in a buffer or non-existent (i.e. an empty message).

Parameters

- **mbox** – Address of the mailbox.
- **tx_msg** – Address of the transmit message descriptor.

- **timeout** – Waiting period for the message to be received, or one of the special values K_NO_WAIT and K_FOREVER. Once the message has been received, this routine waits as long as necessary for the message to be completely processed.

Return values

- **0** – Message sent.
- **-ENOMSG** – Returned without waiting.
- **-EAGAIN** – Waiting period timed out.

void **k_mbox_async_put**(struct *k_mbox* *mbox, struct *k_mbox_msg* *tx_msg, struct k_sem *sem)

Send a mailbox message in an asynchronous manner.

This routine sends a message to *mbox* without waiting for a receiver to process it. The message data may be in a buffer or non-existent (i.e. an empty message). Optionally, the semaphore *sem* will be given when the message has been both received and completely processed by the receiver.

Parameters

- **mbox** – Address of the mailbox.
- **tx_msg** – Address of the transmit message descriptor.
- **sem** – Address of a semaphore, or NULL if none is needed.

int **k_mbox_get**(struct *k_mbox* *mbox, struct *k_mbox_msg* *rx_msg, void *buffer, *k_timeout_t* timeout)

Receive a mailbox message.

This routine receives a message from *mbox*, then optionally retrieves its data and disposes of the message.

Parameters

- **mbox** – Address of the mailbox.
- **rx_msg** – Address of the receive message descriptor.
- **buffer** – Address of the buffer to receive data, or NULL to defer data retrieval and message disposal until later.
- **timeout** – Waiting period for a message to be received, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- **0** – Message received.
- **-ENOMSG** – Returned without waiting.
- **-EAGAIN** – Waiting period timed out.

void **k_mbox_data_get**(struct *k_mbox_msg* *rx_msg, void *buffer)

Retrieve mailbox message data into a buffer.

This routine completes the processing of a received message by retrieving its data into a buffer, then disposing of the message.

Alternatively, this routine can be used to dispose of a received message without retrieving its data.

Parameters

- **rx_msg** – Address of the receive message descriptor.

- **buffer** – Address of the buffer to receive data, or NULL to discard the data.

struct **k_mbox_msg**

#include <*kernel.h*> Mailbox Message Structure.

Public Members

size_t **size**

size of message (in bytes)

uint32_t **info**

application-defined information value

void ***tx_data**

sender's message data buffer

k_tid_t **rx_source_thread**

source thread id

k_tid_t **tx_target_thread**

target thread id

struct **k_mbox**

#include <*kernel.h*> Mailbox Structure.

Public Members

_wait_q_t **tx_msg_queue**

Transmit messages queue.

_wait_q_t **rx_msg_queue**

Receive message queue.

Pipes

A *pipe* is a kernel object that allows a thread to send a byte stream to another thread. Pipes can be used to synchronously transfer chunks of data in whole or in part.

- *Concepts*
- *Implementation*
  - *Writing to a Pipe*
  - *Reading from a Pipe*
  - *Flushing a Pipe's Buffer*

  - *Flushing a Pipe*
- *Suggested uses*
- *Configuration Options*
- *API Reference*

Concepts The pipe can be configured with a ring buffer which holds data that has been sent but not yet received; alternatively, the pipe may have no ring buffer.

Any number of pipes can be defined (limited only by available RAM). Each pipe is referenced by its memory address.

A pipe has the following key property:

- A **size** that indicates the size of the pipe's ring buffer. Note that a size of zero defines a pipe with no ring buffer.

A pipe must be initialized before it can be used. The pipe is initially empty.

Data is synchronously **sent** either in whole or in part to a pipe by a thread. If the specified minimum number of bytes can not be immediately satisfied, then the operation will either fail immediately or attempt to send as many bytes as possible and then pend in the hope that the send can be completed later. Accepted data is either copied to the pipe's ring buffer or directly to the waiting reader(s).

Data is synchronously **received** from a pipe by a thread. If the specified minimum number of bytes can not be immediately satisfied, then the operation will either fail immediately or attempt to receive as many bytes as possible and then pend in the hope that the receive can be completed later. Accepted data is either copied from the pipe's ring buffer or directly from the waiting sender(s).

Data may also be **flushed** from a pipe by a thread. Flushing can be performed either on the entire pipe or on only its ring buffer. Flushing the entire pipe is equivalent to reading all the information in the ring buffer **and** waiting to be written into a giant temporary buffer which is then discarded. Flushing the ring buffer is equivalent to reading **only** the data in the ring buffer into a temporary buffer which is then discarded. Flushing the ring buffer does not guarantee that the ring buffer will stay empty; flushing it may allow a pended writer to fill the ring buffer.

Note

Flushing does not in practice allocate or use additional buffers.

Note

The kernel does allow for an ISR to flush a pipe from an ISR. It also allows it to send/receive data to/from one provided it does not attempt to wait for space/data.

Implementation A pipe is defined using a variable of type `k_pipe` and an optional character buffer of type `unsigned char`. It must then be initialized by calling `k_pipe_init()`.

The following code defines and initializes an empty pipe that has a ring buffer capable of holding 100 bytes and is aligned to a 4-byte boundary.

```
unsigned char __aligned(4) my_ring_buffer[100];
struct k_pipe my_pipe;

k_pipe_init(&my_pipe, my_ring_buffer, sizeof(my_ring_buffer));
```

Alternatively, a pipe can be defined and initialized at compile time by calling *K_PIPE_DEFINE*.

The following code has the same effect as the code segment above. Observe that macro defines both the pipe and its ring buffer.

```
K_PIPE_DEFINE(my_pipe, 100, 4);
```

Writing to a Pipe Data is added to a pipe by calling *k_pipe_put()*.

The following code builds on the example above, and uses the pipe to pass data from a producing thread to one or more consuming threads. If the pipe's ring buffer fills up because the consumers can't keep up, the producing thread waits for a specified amount of time.

```
struct message_header {
    ...
};

void producer_thread(void)
{
    unsigned char *data;
    size_t total_size;
    size_t bytes_written;
    int    rc;
    ...

    while (1) {
        /* Craft message to send in the pipe */
        data = ...;
        total_size = ...;

        /* send data to the consumers */
        rc = k_pipe_put(&my_pipe, data, total_size, &bytes_written,
                        sizeof(struct message_header), K_NO_WAIT);

        if (rc < 0) {
            /* Incomplete message header sent */
            ...
        } else if (bytes_written < total_size) {
            /* Some of the data was sent */
            ...
        } else {
            /* All data sent */
            ...
        }
    }
}
```

Reading from a Pipe Data is read from the pipe by calling *k_pipe_get()*.

The following code builds on the example above, and uses the pipe to process data items generated by one or more producing threads.

```
void consumer_thread(void)
{
    unsigned char buffer[120];
```

(continues on next page)

(continued from previous page)

```
    size_t   bytes_read;
    struct message_header  *header = (struct message_header *)buffer;

    while (1) {
        rc = k_pipe_get(&my_pipe, buffer, sizeof(buffer), &bytes_read,
                        sizeof(*header), K_MSEC(100));

        if ((rc < 0) || (bytes_read < sizeof (*header))) {
            /* Incomplete message header received */
            ...
        } else if (header->num_data_bytes + sizeof(*header) > bytes_read) {
            /* Only some data was received */
            ...
        } else {
            /* All data was received */
            ...
        }
    }
}
```

Use a pipe to send streams of data between threads.

Note

A pipe can be used to transfer long streams of data if desired. However it is often preferable to send pointers to large data items to avoid copying the data.

Flushing a Pipe's Buffer Data is flushed from the pipe's ring buffer by calling *k_pipe_buffer_flush()*.

The following code builds on the examples above, and flushes the pipe's buffer.

```
void monitor_thread(void)
{
    while (1) {
        ...
        /* Pipe buffer contains stale data. Flush it. */
        k_pipe_buffer_flush(&my_pipe);
        ...
    }
}
```

Flushing a Pipe All data in the pipe is flushed by calling *k_pipe_flush()*.

The following code builds on the examples above, and flushes all the data in the pipe.

```
void monitor_thread(void)
{
    while (1) {
        ...
        /* Critical error detected. Flush the entire pipe to reset it. */
        k_pipe_flush(&my_pipe);
        ...
    }
}
```

Suggested uses Use a pipe to send streams of data between threads.

> **Note**
>
> A pipe can be used to transfer long streams of data if desired. However it is often preferable to send pointers to large data items to avoid copying the data. Copying large data items will negatively impact interrupt latency as a spinlock is held while copying that data.

Configuration Options Related configuration options:

- `CONFIG_PIPES`

API Reference

group `pipe_apis`

Defines

`K_PIPE_DEFINE`(name, pipe_buffer_size, pipe_align)

Statically define and initialize a pipe.

The pipe can be accessed outside the module where it is defined using:

```
extern struct k_pipe <name>;
```

Parameters

- **`name`** – Name of the pipe.
- **`pipe_buffer_size`** – Size of the pipe's ring buffer (in bytes), or zero if no ring buffer is used.
- **`pipe_align`** – Alignment of the pipe's ring buffer (power of 2).

Functions

void `k_pipe_init`(struct *k_pipe* *pipe, unsigned char *buffer, size_t size)

Initialize a pipe.

This routine initializes a pipe object, prior to its first use.

Parameters

- **`pipe`** – Address of the pipe.
- **`buffer`** – Address of the pipe's ring buffer, or NULL if no ring buffer is used.
- **`size`** – Size of the pipe's ring buffer (in bytes), or zero if no ring buffer is used.

int `k_pipe_cleanup`(struct *k_pipe* *pipe)

Release a pipe's allocated buffer.

If a pipe object was given a dynamically allocated buffer via *k_pipe_alloc_init()*, this will free it. This function does nothing if the buffer wasn't dynamically allocated.

Parameters

- **pipe** – Address of the pipe.

Return values

- **0** – on success
- **-EAGAIN** – nothing to cleanup

int **k_pipe_alloc_init**(struct *k_pipe* *pipe, size_t size)

Initialize a pipe and allocate a buffer for it.

Storage for the buffer region will be allocated from the calling thread's resource pool. This memory will be released if *k_pipe_cleanup()* is called, or userspace is enabled and the pipe object loses all references to it.

This function should only be called on uninitialized pipe objects.

Parameters

- **pipe** – Address of the pipe.
- **size** – Size of the pipe's ring buffer (in bytes), or zero if no ring buffer is used.

Return values

- **0** – on success
- **-ENOMEM** – if memory couldn't be allocated

int **k_pipe_put**(struct *k_pipe* *pipe, const void *data, size_t bytes_to_write, size_t *bytes_written, size_t min_xfer, *k_timeout_t* timeout)

Write data to a pipe.

This routine writes up to *bytes_to_write* bytes of data to *pipe*.

Parameters

- **pipe** – Address of the pipe.
- **data** – Address of data to write.
- **bytes_to_write** – Size of data (in bytes).
- **bytes_written** – Address of area to hold the number of bytes written.
- **min_xfer** – Minimum number of bytes to write.
- **timeout** – Waiting period to wait for the data to be written, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- **0** – At least *min_xfer* bytes of data were written.
- **-EIO** – Returned without waiting; zero data bytes were written.
- **-EAGAIN** – Waiting period timed out; between zero and *min_xfer* minus one data bytes were written.

int **k_pipe_get**(struct *k_pipe* *pipe, void *data, size_t bytes_to_read, size_t *bytes_read, size_t min_xfer, *k_timeout_t* timeout)

Read data from a pipe.

This routine reads up to *bytes_to_read* bytes of data from *pipe*.

Parameters

- **pipe** – Address of the pipe.
- **data** – Address to place the data read from pipe.
- **bytes_to_read** – Maximum number of data bytes to read.

- **bytes_read** – Address of area to hold the number of bytes read.
- **min_xfer** – Minimum number of data bytes to read.
- **timeout** – Waiting period to wait for the data to be read, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- **0** – At least *min_xfer* bytes of data were read.
- **-EINVAL** – invalid parameters supplied
- **-EIO** – Returned without waiting; zero data bytes were read.
- **-EAGAIN** – Waiting period timed out; between zero and *min_xfer* minus one data bytes were read.

size_t **k_pipe_read_avail**(struct *k_pipe* *pipe)

Query the number of bytes that may be read from *pipe*.

Parameters

- **pipe** – Address of the pipe.

Return values

a – number n such that 0 <= n <= *k_pipe::size*; the result is zero for unbuffered pipes.

size_t **k_pipe_write_avail**(struct *k_pipe* *pipe)

Query the number of bytes that may be written to *pipe*.

Parameters

- **pipe** – Address of the pipe.

Return values

a – number n such that 0 <= n <= *k_pipe::size*; the result is zero for unbuffered pipes.

void **k_pipe_flush**(struct *k_pipe* *pipe)

Flush the pipe of write data.

This routine flushes the pipe. Flushing the pipe is equivalent to reading both all the data in the pipe's buffer and all the data waiting to go into that pipe into a large temporary buffer and discarding the buffer. Any writers that were previously pended become unpended.

Parameters

- **pipe** – Address of the pipe.

void **k_pipe_buffer_flush**(struct *k_pipe* *pipe)

Flush the pipe's internal buffer.

This routine flushes the pipe's internal buffer. This is equivalent to reading up to N bytes from the pipe (where N is the size of the pipe's buffer) into a temporary buffer and then discarding that buffer. If there were writers previously pending, then some may unpend as they try to fill up the pipe's emptied buffer.

Parameters

- **pipe** – Address of the pipe.

struct **k_pipe**

#include <kernel.h> Pipe Structure.

Public Members

unsigned char *`buffer`
: Pipe buffer: may be NULL.

size_t `size`
: Buffer size.

size_t `bytes_used`
: Number of bytes used in buffer.

size_t `read_index`
: Where in buffer to read from.

size_t `write_index`
: Where in buffer to write.

struct *k_spinlock* `lock`
: Synchronization lock.

_wait_q_t `readers`
: Reader wait queue.

_wait_q_t `writers`
: Writer wait queue.

uint8_t `flags`
: Wait queue.

3.1.3 Memory Management

See *Memory Management*.

3.1.4 Timing

These pages cover timing related services.

Kernel Timing

Zephyr provides a robust and scalable timing framework to enable reporting and tracking of timed events from hardware timing sources of arbitrary precision.

Time Units Kernel time is tracked in several units which are used for different purposes.

Real time values, typically specified in milliseconds or microseconds, are the default presentation of time to application code. They have the advantages of being universally portable and pervasively understood, though they may not match the precision of the underlying hardware perfectly.

The kernel presents a "cycle" count via the *k_cycle_get_32()* and *k_cycle_get_64()* APIs. The intent is that this counter represents the fastest cycle counter that the operating system is able to present to the user (for example, a CPU cycle counter) and that the read operation is very fast. The expectation is that very sensitive application code might use this in a polling manner to achieve maximal precision. The frequency of this counter is required to be steady over time, and is available from `sys_clock_hw_cycles_per_sec()` (which on almost all platforms is a runtime constant that evaluates to CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC).

For asynchronous timekeeping, the kernel defines a "ticks" concept. A "tick" is the internal count in which the kernel does all its internal uptime and timeout bookkeeping. Interrupts are expected to be delivered on tick boundaries to the extent practical, and no fractional ticks are tracked. The choice of tick rate is configurable via `CONFIG_SYS_CLOCK_TICKS_PER_SEC`. Defaults on most hardware platforms (ones that support setting arbitrary interrupt timeouts) are expected to be in the range of 10 kHz, with software emulation platforms and legacy drivers using a more traditional 100 Hz value.

Conversion Zephyr provides an extensively enumerated conversion library with rounding control for all time units. Any unit of "ms" (milliseconds), "us" (microseconds), "tick", or "cyc" can be converted to any other. Control of rounding is provided, and each conversion is available in "floor" (round down to nearest output unit), "ceil" (round up) and "near" (round to nearest). Finally the output precision can be specified as either 32 or 64 bits.

For example: `k_ms_to_ticks_ceil32()` will convert a millisecond input value to the next higher number of ticks, returning a result truncated to 32 bits of precision; and `k_cyc_to_us_floor64()` will convert a measured cycle count to an elapsed number of microseconds in a full 64 bits of precision. See the reference documentation for the full enumeration of conversion routines.

On most platforms, where the various counter rates are integral multiples of each other and where the output fits within a single word, these conversions expand to a 2-4 operation sequence, requiring full precision only where actually required and requested.

Uptime The kernel tracks a system uptime count on behalf of the application. This is available at all times via *k_uptime_get()*, which provides an uptime value in milliseconds since system boot. This is expected to be the utility used by most portable application code.

The internal tracking, however, is as a 64 bit integer count of ticks. Apps with precise timing requirements (that are willing to do their own conversions to portable real time units) may access this with *k_uptime_ticks()*.

Timeouts The Zephyr kernel provides many APIs with a "timeout" parameter. Conceptually, this indicates the time at which an event will occur. For example:

- Kernel blocking operations like *k_sem_take()* or *k_queue_get()* may provide a timeout after which the routine will return with an error code if no data is available.
- Kernel `k_timer` objects must specify delays for their duration and period.
- The kernel *k_work_delayable* API provides a timeout parameter indicating when a work queue item will be added to the system queue.

All these values are specified using a *k_timeout_t* value. This is an opaque struct type that must be initialized using one of a family of kernel timeout macros. The most common, *K_MSEC*, defines a time in milliseconds after the current time.

What is meant by "current time" for relative timeouts depends on the context:

- When scheduling a relative timeout from within a timeout callback (e.g. from within the expiry function passed to *k_timer_init()* or the work handler passed to *k_work_init_delayable()*), "current time" is the exact time at which the currently firing timeout was originally scheduled even if the "real time" will already have advanced. This is to ensure that timers scheduled from within another timer's callback will always be calculated with a precise offset to the firing timer. It is thereby possible to fire at regular intervals without introducing systematic clock drift over time.
- When scheduling a timeout from application context, "current time" means the value returned by *k_uptime_ticks()* at the time at which the kernel receives the timeout value.

Other options for timeout initialization follow the unit conventions described above: *K_NSEC()*, *K_USEC*, *K_TICKS* and *K_CYC()* specify timeout values that will expire after specified numbers of nanoseconds, microseconds, ticks and cycles, respectively.

Precision of *k_timeout_t* values is configurable, with the default being 32 bits. Large uptime counts in non-tick units will experience complicated rollover semantics, so it is expected that timing-sensitive applications with long uptimes will be configured to use a 64 bit timeout type.

Finally, it is possible to specify timeouts as absolute times since system boot. A timeout initialized with `K_TIMEOUT_ABS_MS` indicates a timeout that will expire after the system uptime reaches the specified value. There are likewise nanosecond, microsecond, cycles and ticks variants of this API.

Timing Internals

Timeout Queue All Zephyr *k_timeout_t* events specified using the API above are managed in a single, global queue of events. Each event is stored in a double-linked list, with an attendant delta count in ticks from the previous event. The action to take on an event is specified as a callback function pointer provided by the subsystem requesting the event, along with a `_timeout` tracking struct that is expected to be embedded within subsystem-defined data structures (for example: a `wait_q` struct, or a `k_tid_t` thread struct).

Note that all variant units passed via a *k_timeout_t* are converted to ticks once on insertion into the list. There no multiple-conversion steps internal to the kernel, so precision is guaranteed at the tick level no matter how many events exist or how long a timeout might be.

Note that the list structure means that the CPU work involved in managing large numbers of timeouts is quadratic in the number of active timeouts. The API design of the timeout queue was intended to permit a more scalable backend data structure, but no such implementation exists currently.

Timer Drivers Kernel timing at the tick level is driven by a timer driver with a comparatively simple API.

- The driver is expected to be able to "announce" new ticks to the kernel via the *sys_clock_announce()* call, which passes an integer number of ticks that have elapsed since the last announce call (or system boot). These calls can occur at any time, but the driver is expected to attempt to ensure (to the extent practical given interrupt latency interactions) that they occur near tick boundaries (i.e. not "halfway through" a tick), and most importantly that they be correct over time and subject to minimal skew vs. other counters and real world time.
- The driver is expected to provide a *sys_clock_set_timeout()* call to the kernel which indicates how many ticks may elapse before the kernel must receive an announce call to trigger registered timeouts. It is legal to announce new ticks before that moment (though they must be correct) but delay after that will cause events to be missed. Note that the timeout value passed here is in a delta from current time, but that does not absolve the driver of

the requirement to provide ticks at a steady rate over time. Naive implementations of this function are subject to bugs where the fractional tick gets "reset" incorrectly and causes clock skew.

- The driver is expected to provide a *sys_clock_elapsed()* call which provides a current indication of how many ticks have elapsed (as compared to a real world clock) since the last call to *sys_clock_announce()*, which the kernel needs to test newly arriving timeouts for expiration.

Note that a natural implementation of this API results in a "tickless" kernel, which receives and processes timer interrupts only for registered events, relying on programmable hardware counters to provide irregular interrupts. But a traditional, "ticked" or "dumb" counter driver can be trivially implemented also:

- The driver can receive interrupts at a regular rate corresponding to the OS tick rate, calling *sys_clock_announce()* with an argument of one each time.
- The driver can ignore calls to *sys_clock_set_timeout()*, as every tick will be announced regardless of timeout status.
- The driver can return zero for every call to *sys_clock_elapsed()* as no more than one tick can be detected as having elapsed (because otherwise an interrupt would have been received).

SMP Details In general, the timer API described above does not change when run in a multiprocessor context. The kernel will internally synchronize all access appropriately, and ensure that all critical sections are small and minimal. But some notes are important to detail:

- Zephyr is agnostic about which CPU services timer interrupts. It is not illegal (though probably undesirable in some circumstances) to have every timer interrupt handled on a single processor. Existing SMP architectures implement symmetric timer drivers.
- The *sys_clock_announce()* call is expected to be globally synchronized at the driver level. The kernel does not do any per-CPU tracking, and expects that if two timer interrupts fire near simultaneously, that only one will provide the current tick count to the timing subsystem. The other may legally provide a tick count of zero if no ticks have elapsed. It should not "skip" the announce call because of timeslicing requirements (see below).
- Some SMP hardware uses a single, global timer device, others use a per-CPU counter. The complexity here (for example: ensuring counter synchronization between CPUs) is expected to be managed by the driver, not the kernel.
- The next timeout value passed back to the driver via *sys_clock_set_timeout()* is done identically for every CPU. So by default, every CPU will see simultaneous timer interrupts for every event, even though by definition only one of them should see a non-zero ticks argument to *sys_clock_announce()*. This is probably a correct default for timing sensitive applications (because it minimizes the chance that an errant ISR or interrupt lock will delay a timeout), but may be a performance problem in some cases. The current design expects that any such optimization is the responsibility of the timer driver.

Time Slicing An auxiliary job of the timing subsystem is to provide tick counters to the scheduler that allow implementation of time slicing of threads. A thread time-slice cannot be a timeout value, as it does not reflect a global expiration but instead a per-CPU value that needs to be tracked independently on each CPU in an SMP context.

Because there may be no other hardware available to drive timeslicing, Zephyr multiplexes the existing timer driver. This means that the value passed to *sys_clock_set_timeout()* may be clamped to a smaller value than the current next timeout when a time sliced thread is currently scheduled.

Subsystems that keep millisecond APIs In general, code like this will port just like applications code will. Millisecond values from the user may be treated any way the subsystem likes, and then converted into kernel timeouts using *K_MSEC()* at the point where they are presented to the kernel.

Obviously this comes at the cost of not being able to use new features, like the higher precision timeout constructors or absolute timeouts. But for many subsystems with simple needs, this may be acceptable.

One complexity is *K_FOREVER*. Subsystems that might have been able to accept this value to their millisecond API in the past no longer can, because it is no longer an integral type. Such code will need to use a different, integer-valued token to represent "forever". *K_NO_WAIT* has the same typesafety concern too, of course, but as it is (and has always been) simply a numerical zero, it has a natural porting path.

Subsystems using k_timeout_t Ideally, code that takes a "timeout" parameter specifying a time to wait should be using the kernel native abstraction where possible. But *k_timeout_t* is opaque, and needs to be converted before it can be inspected by an application.

Some conversions are simple. Code that needs to test for *K_FOREVER* can simply use the *K_TIMEOUT_EQ()* macro to test the opaque struct for equality and take special action.

The more complicated case is when the subsystem needs to take a timeout and loop, waiting for it to finish while doing some processing that may require multiple blocking operations on underlying kernel code. For example, consider this design:

```
void my_wait_for_event(struct my_subsys *obj, int32_t timeout_in_ms)
{
    while (true) {
        uint32_t start = k_uptime_get_32();

        if (is_event_complete(obj)) {
            return;
        }

        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout_in_ms);

        /* Subtract elapsed time */
        timeout_in_ms -= (k_uptime_get_32() - start);
    }
}
```

This code requires that the timeout value be inspected, which is no longer possible. For situations like this, the new API provides the internal *sys_timepoint_calc()* and *sys_timepoint_timeout()* routines that converts an arbitrary timeout to and from a timepoint value based on an uptime tick at which it will expire. So such a loop might look like:

```
void my_wait_for_event(struct my_subsys *obj, k_timeout_t timeout)
{
    /* Compute the end time from the timeout */
    k_timepoint_t end = sys_timepoint_calc(timeout);

    do {
        if (is_event_complete(obj)) {
            return;
        }

        /* Update timeout with remaining time */
        timeout = sys_timepoint_timeout(end);
```

(continues on next page)

(continued from previous page)

```
        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout);
    } while (!K_TIMEOUT_EQ(timeout, K_NO_WAIT));
}
```

Note that *sys_timepoint_calc()* accepts special values *K_FOREVER* and *K_NO_WAIT*, and works identically for absolute timeouts as well as conventional ones. Conversely, *sys_timepoint_timeout()* may return *K_FOREVER* or *K_NO_WAIT* if those were used to create the timepoint, the later also being returned if the timepoint is now in the past. For simple cases, *sys_timepoint_expired()* can be used as well.

But some care is still required for subsystems that use those. Note that delta timeouts need to be interpreted relative to a "current time", and obviously that time is the time of the call to *sys_timepoint_calc()*. But the user expects that the time is the time they passed the timeout to you. Care must be taken to call this function just once, as synchronously as possible to the timeout creation in user code. It should not be used on a "stored" timeout value, and should never be called iteratively in a loop.

API Reference

group `clock_apis`

System Clock APIs.

Defines

`K_NO_WAIT`

Generate null timeout delay.

This macro generates a timeout delay that instructs a kernel API not to wait if the requested operation cannot be performed immediately.

Returns
Timeout delay value.

`K_NSEC`(t)

Generate timeout delay from nanoseconds.

This macro generates a timeout delay that instructs a kernel API to wait up to *t* nanoseconds to perform the requested operation. Note that timer precision is limited to the tick rate, not the requested value.

Parameters

- **t** – Duration in nanoseconds.

Returns
Timeout delay value.

`K_USEC`(t)

Generate timeout delay from microseconds.

This macro generates a timeout delay that instructs a kernel API to wait up to *t* microseconds to perform the requested operation. Note that timer precision is limited to the tick rate, not the requested value.

Parameters

- **t** – Duration in microseconds.

Returns
Timeout delay value.

K_CYC(t)

Generate timeout delay from cycles.

This macro generates a timeout delay that instructs a kernel API to wait up to *t* cycles to perform the requested operation.

Parameters

- **t** – Duration in cycles.

Returns
Timeout delay value.

K_TICKS(t)

Generate timeout delay from system ticks.

This macro generates a timeout delay that instructs a kernel API to wait up to *t* ticks to perform the requested operation.

Parameters

- **t** – Duration in system ticks.

Returns
Timeout delay value.

K_MSEC(ms)

Generate timeout delay from milliseconds.

This macro generates a timeout delay that instructs a kernel API to wait up to *ms* milliseconds to perform the requested operation.

Parameters

- **ms** – Duration in milliseconds.

Returns
Timeout delay value.

K_SECONDS(s)

Generate timeout delay from seconds.

This macro generates a timeout delay that instructs a kernel API to wait up to *s* seconds to perform the requested operation.

Parameters

- **s** – Duration in seconds.

Returns
Timeout delay value.

K_MINUTES(m)

Generate timeout delay from minutes.

This macro generates a timeout delay that instructs a kernel API to wait up to *m* minutes to perform the requested operation.

Parameters

- **m** – Duration in minutes.

Returns
Timeout delay value.

K_HOURS(h)

Generate timeout delay from hours.

This macro generates a timeout delay that instructs a kernel API to wait up to *h* hours to perform the requested operation.

Parameters

- h – Duration in hours.

Returns
Timeout delay value.

K_FOREVER

Generate infinite timeout delay.

This macro generates a timeout delay that instructs a kernel API to wait as long as necessary to perform the requested operation.

Returns
Timeout delay value.

K_TICKS_FOREVER

K_TIMEOUT_EQ(a, b)

Compare timeouts for equality.

The *k_timeout_t* object is an opaque struct that should not be inspected by application code. This macro exists so that users can test timeout objects for equality with known constants (e.g. K_NO_WAIT and K_FOREVER) when implementing their own APIs in terms of Zephyr timeout constants.

Returns
True if the timeout objects are identical

NSEC_PER_USEC

number of nanoseconds per micorsecond

NSEC_PER_MSEC

number of nanoseconds per millisecond

USEC_PER_MSEC

number of microseconds per millisecond

MSEC_PER_SEC

number of milliseconds per second

SEC_PER_MIN

number of seconds per minute

MIN_PER_HOUR

number of minutes per hour

HOUR_PER_DAY

number of hours per day

USEC_PER_SEC

number of microseconds per second

NSEC_PER_SEC

number of nanoseconds per second

SYS_CLOCK_HW_CYCLES_TO_NS_AVG(X, NCYCLES)

SYS_CLOCK_HW_CYCLES_TO_NS_AVG converts CPU clock cycles to nanoseconds and calculates the average cycle time.

Typedefs

typedef uint32_t **k_ticks_t**

Tick precision used in timeout APIs.

This type defines the word size of the timeout values used in *k_timeout_t* objects, and thus defines an upper bound on maximum timeout length (or equivalently minimum tick duration). Note that this does not affect the size of the system uptime counter, which is always a 64 bit count of ticks.

Functions

void **sys_clock_set_timeout**(int32_t ticks, bool idle)

Set system clock timeout.

Informs the system clock driver that the next needed call to *sys_clock_announce()* will not be until the specified number of ticks from the current time have elapsed. Note that spurious calls to *sys_clock_announce()* are allowed (i.e. it's legal to announce every tick and implement this function as a noop), the requirement is that one tick announcement should occur within one tick BEFORE the specified expiration (that is, passing ticks==1 means "announce

the next tick", this convention was chosen to match legacy usage). Similarly a ticks value of zero (or even negative) is legal and treated identically: it simply indicates the kernel would like the next tick announcement as soon as possible.

Note that ticks can also be passed the special value K_TICKS_FOREVER, indicating that no future timer interrupts are expected or required and that the system is permitted to enter an indefinite sleep even if this could cause rollover of the internal counter (i.e. the system uptime counter is allowed to be wrong

Note also that it is conventional for the kernel to pass INT_MAX for ticks if it wants to preserve the uptime tick count but doesn't have a specific event to await. The intent here is that the driver will schedule any needed timeout as far into the future as possible. For the specific case of INT_MAX, the next call to *sys_clock_announce()* may occur at any point in the future, not just at INT_MAX ticks. But the correspondence between the announced ticks and real-world time must be correct.

A final note about SMP: note that the call to *sys_clock_set_timeout()* is made on any CPU, and reflects the next timeout desired globally. The resulting calls(s) to *sys_clock_announce()* must be properly serialized by the driver such that a given tick is announced exactly once across the system. The kernel does not (cannot, really) attempt to serialize things by "assigning" timeouts to specific CPUs.

Parameters

- **ticks** – Timeout in tick units

- **idle** – Hint to the driver that the system is about to enter the idle state immediately after setting the timeout

void **sys_clock_idle_exit**(void)

Timer idle exit notification.

This notifies the timer driver that the system is exiting the idle and allows it to do whatever bookkeeping is needed to restore timer operation and compute elapsed ticks.

> **Note**
>
> Legacy timer drivers also use this opportunity to call back into *sys_clock_announce()* to notify the kernel of expired ticks. This is allowed for compatibility, but not recommended. The kernel will figure that out on its own.

void **sys_clock_announce**(int32_t ticks)

Announce time progress to the kernel.

Informs the kernel that the specified number of ticks have elapsed since the last call to *sys_clock_announce()* (or system startup for the first call). The timer driver is expected to delivery these announcements as close as practical (subject to hardware and latency limitations) to tick boundaries.

Parameters

- **ticks** – Elapsed time, in ticks

uint32_t **sys_clock_elapsed**(void)

Ticks elapsed since last *sys_clock_announce()* call.

Queries the clock driver for the current time elapsed since the last call to *sys_clock_announce()* was made. The kernel will call this with appropriate locking, the driver needs only provide an instantaneous answer.

void **sys_clock_disable**(void)

Disable system timer.

> **Note**
>
> Not all system timer drivers has the capability of being disabled. The config CONFIG_SYSTEM_TIMER_HAS_DISABLE_SUPPORT can be used to check if the system timer has the capability of being disabled.

uint32_t **sys_clock_cycle_get_32**(void)

Hardware cycle counter.

Timer drivers are generally responsible for the system cycle counter as well as the tick announcements. This function is generally called out of the architecture layer (

> **See also**
>
> arch_k_cycle_get_32()) to implement the cycle counter, though the user-facing API is owned by the architecture, not the driver. The rate must match CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC.

Note

If the counter clock is large enough for this to wrap its full range within a few seconds (i.e. CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC is greater than 50Mhz) then it is recommended to also implement *sys_clock_cycle_get_64()*.

Returns

The current cycle time. This should count up monotonically through the full 32 bit space, wrapping at 0xffffffff. Hardware with fewer bits of precision in the timer is expected to synthesize a 32 bit count.

uint64_t **sys_clock_cycle_get_64**(void)

64 bit hardware cycle counter

As for *sys_clock_cycle_get_32()*, but with a 64 bit return value. Not all hardware has 64 bit counters. This function need be implemented only if CONFIG_TIMER_HAS_64BIT_CYCLE_COUNTER is set.

Note

If the counter clock is large enough for *sys_clock_cycle_get_32()* to wrap its full range within a few seconds (i.e. CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC is greater than 50Mhz) then it is recommended to implement this API.

Returns

The current cycle time. This should count up monotonically through the full 64 bit space, wrapping at 2^64-1. Hardware with fewer bits of precision in the timer is generally not expected to implement this API.

int64_t **k_uptime_ticks**(void)

Get system uptime, in system ticks.

This routine returns the elapsed time since the system booted, in ticks (c.f. `CONFIG_SYS_CLOCK_TICKS_PER_SEC`), which is the fundamental unit of resolution of kernel timekeeping.

Returns

Current uptime in ticks.

static inline int64_t **k_uptime_get**(void)

Get system uptime.

This routine returns the elapsed time since the system booted, in milliseconds.

Note

While this function returns time in milliseconds, it does not mean it has millisecond resolution. The actual resolution depends on `CONFIG_SYS_CLOCK_TICKS_PER_SEC` config option.

Returns

Current uptime in milliseconds.

static inline uint32_t **k_uptime_get_32**(void)

Get system uptime (32-bit version).

This routine returns the lower 32 bits of the system uptime in milliseconds.

Because correct conversion requires full precision of the system clock there is no benefit to using this over *k_uptime_get()* unless you know the application will never run long enough for the system clock to approach 2^32 ticks. Calls to this function may involve interrupt blocking and 64-bit math.

Note

While this function returns time in milliseconds, it does not mean it has millisecond resolution. The actual resolution depends on `CONFIG_SYS_CLOCK_TICKS_PER_SEC` config option

Returns
The low 32 bits of the current uptime, in milliseconds.

static inline uint32_t **k_uptime_seconds**(void)

Get system uptime in seconds.

This routine returns the elapsed time since the system booted, in seconds.

Returns
Current uptime in seconds.

static inline int64_t **k_uptime_delta**(int64_t *reftime)

Get elapsed time.

This routine computes the elapsed time between the current system uptime and an earlier reference time, in milliseconds.

Parameters

- **reftime** – Pointer to a reference time, which is updated to the current uptime upon return.

Returns
Elapsed time.

static inline uint32_t **k_cycle_get_32**(void)

Read the hardware clock.

This routine returns the current time, as measured by the system's hardware clock.

Returns
Current hardware clock up-counter (in cycles).

static inline uint64_t **k_cycle_get_64**(void)

Read the 64-bit hardware clock.

This routine returns the current time in 64-bits, as measured by the system's hardware clock, if available.

See also

CONFIG_TIMER_HAS_64BIT_CYCLE_COUNTER

Returns
Current hardware clock up-counter (in cycles).

uint32_t **sys_clock_tick_get_32**(void)

Return the lower part of the current system tick count.

Returns
the current system tick count

int64_t **sys_clock_tick_get**(void)

Return the current system tick count.

Returns
the current system tick count

k_timepoint_t **sys_timepoint_calc**(*k_timeout_t* timeout)

Calculate a timepoint value.

Returns a timepoint corresponding to the expiration (relative to an unlocked "now"!) of a timeout object. When used correctly, this should be called once, synchronously with the user passing a new timeout value. It should not be used iteratively to adjust a timeout (see *sys_timepoint_timeout()* for that purpose).

See also

sys_timepoint_timeout()

See also

sys_timepoint_expired()

Parameters

- **timeout** – Timeout value relative to current time (may also be K_FOREVER or K_NO_WAIT).

Return values
Timepoint – value corresponding to given timeout

k_timeout_t **sys_timepoint_timeout**(*k_timepoint_t* timepoint)

Remaining time to given timepoint.

Returns the timeout interval between current time and provided timepoint. If the timepoint is now in the past or if it was created with K_NO_WAIT then K_NO_WAIT is returned. If it was created with K_FOREVER then K_FOREVER is returned.

See also

sys_timepoint_calc()

Parameters

- **timepoint** – Timepoint for which a timeout value is wanted.

Return values
`Corresponding` – timeout value.

static inline uint64_t **sys_clock_timeout_end_calc**(*k_timeout_t* timeout)

Provided for backward compatibility.

This is deprecated. Consider *sys_timepoint_calc()* instead.

See also

sys_timepoint_calc()

static inline int **sys_timepoint_cmp**(*k_timepoint_t* a, *k_timepoint_t* b)

Compare two timepoint values.

This function is used to compare two timepoint values.

Parameters

- `a` – Timepoint to compare
- `b` – Timepoint to compare against.

Returns
zero if both timepoints are the same. Negative value if timepoint *a* is before timepoint *b*, positive otherwise.

static inline bool **sys_timepoint_expired**(*k_timepoint_t* timepoint)

Indicates if timepoint is expired.

See also

sys_timepoint_calc()

Parameters

- `timepoint` – Timepoint to evaluate

Return values
`true` – if the timepoint is in the past, false otherwise

struct **k_timeout_t**

#include <*sys_clock.h*> Kernel timeout type.

Timeout arguments presented to kernel APIs are stored in this opaque type, which is capable of representing times in various formats and units. It should be constructed from application data using one of the macros defined for this purpose (e.g. *K_MSEC()*, `K_TIMEOUT_ABS_TICKS()`, etc...), or be one of the two constants K_NO_WAIT or K_FOREVER. Applications should not inspect the internal data once constructed. Timeout values may be compared for equality with the *K_TIMEOUT_EQ()* macro.

struct **k_timepoint_t**

#include <*sys_clock.h*> Kernel timepoint type.

Absolute timepoints are stored in this opaque type. It is best not to inspect its content directly.

Timers

A *timer* is a kernel object that measures the passage of time using the kernel's system clock. When a timer's specified time limit is reached it can perform an application-defined action, or it can simply record the expiration and wait for the application to read its status.

- *Concepts*
- *Implementation*
  - *Defining a Timer*
  - *Using a Timer Expiry Function*
  - *Reading Timer Status*
  - *Using Timer Status Synchronization*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of timers can be defined (limited only by available RAM). Each timer is referenced by its memory address.

A timer has the following key properties:

- A **duration** specifying the time interval before the timer expires for the first time. This is a `k_timeout_t` value that may be initialized via different units.
- A **period** specifying the time interval between all timer expirations after the first one, also a `k_timeout_t`. It must be non-negative. A period of `K_NO_WAIT` (i.e. zero) or `K_FOREVER` means that the timer is a one-shot timer that stops after a single expiration. (For example then, if a timer is started with a duration of 200 and a period of 75, it will first expire after 200 ms and then every 75 ms after that.)
- An **expiry function** that is executed each time the timer expires. The function is executed by the system clock interrupt handler. If no expiry function is required a `NULL` function can be specified.

- A **stop function** that is executed if the timer is stopped prematurely while running. The function is executed by the thread that stops the timer. If no stop function is required a `NULL` function can be specified.
- A **status** value that indicates how many times the timer has expired since the status value was last read.

A timer must be initialized before it can be used. This specifies its expiry function and stop function values, sets the timer's status to zero, and puts the timer into the **stopped** state.

A timer is **started** by specifying a duration and a period. The timer's status is reset to zero, and then the timer enters the **running** state and begins counting down towards expiry.

Note that the timer's duration and period parameters specify **minimum** delays that will elapse. Because of internal system timer precision (and potentially runtime interactions like interrupt delay) it is possible that more time may have passed as measured by reads from the relevant system time APIs. But at least this much time is guaranteed to have elapsed.

When a running timer expires its status is incremented and the timer executes its expiry function, if one exists; If a thread is waiting on the timer, it is unblocked. If the timer's period is zero the timer enters the stopped state; otherwise, the timer restarts with a new duration equal to its period.

A running timer can be stopped in mid-countdown, if desired. The timer's status is left unchanged, then the timer enters the stopped state and executes its stop function, if one exists. If a thread is waiting on the timer, it is unblocked. Attempting to stop a non-running timer is permitted, but has no effect on the timer since it is already stopped.

A running timer can be restarted in mid-countdown, if desired. The timer's status is reset to zero, then the timer begins counting down using the new duration and period values specified by the caller. If a thread is waiting on the timer, it continues waiting.

A timer's status can be read directly at any time to determine how many times the timer has expired since its status was last read. Reading a timer's status resets its value to zero. The amount of time remaining before the timer expires can also be read; a value of zero indicates that the timer is stopped.

A thread may read a timer's status indirectly by **synchronizing** with the timer. This blocks the thread until the timer's status is non-zero (indicating that it has expired at least once) or the timer is stopped; if the timer status is already non-zero or the timer is already stopped the thread continues without waiting. The synchronization operation returns the timer's status and resets it to zero.

> **Note**
>
> Only a single user should examine the status of any given timer, since reading the status (directly or indirectly) changes its value. Similarly, only a single thread at a time should synchronize with a given timer. ISRs are not permitted to synchronize with timers, since ISRs are not allowed to block.

Implementation

Defining a Timer A timer is defined using a variable of type `k_timer`. It must then be initialized by calling *`k_timer_init()`*.

The following code defines and initializes a timer.

```
struct k_timer my_timer;
extern void my_expiry_function(struct k_timer *timer_id);
```

(continues on next page)

(continued from previous page)

```
k_timer_init(&my_timer, my_expiry_function, NULL);
```

Alternatively, a timer can be defined and initialized at compile time by calling *K_TIMER_DEFINE*.

The following code has the same effect as the code segment above.

```
K_TIMER_DEFINE(my_timer, my_expiry_function, NULL);
```

Using a Timer Expiry Function The following code uses a timer to perform a non-trivial action on a periodic basis. Since the required work cannot be done at the interrupt level, the timer's expiry function submits a work item to the *system workqueue*, whose thread performs the work.

```
void my_work_handler(struct k_work *work)
{
    /* do the processing that needs to be done periodically */
    ...
}

K_WORK_DEFINE(my_work, my_work_handler);

void my_timer_handler(struct k_timer *dummy)
{
    k_work_submit(&my_work);
}

K_TIMER_DEFINE(my_timer, my_timer_handler, NULL);

...

/* start a periodic timer that expires once every second */
k_timer_start(&my_timer, K_SECONDS(1), K_SECONDS(1));
```

Reading Timer Status The following code reads a timer's status directly to determine if the timer has expired or not.

```
K_TIMER_DEFINE(my_status_timer, NULL, NULL);

...

/* start a one-shot timer that expires after 200 ms */
k_timer_start(&my_status_timer, K_MSEC(200), K_NO_WAIT);

/* do work */
...

/* check timer status */
if (k_timer_status_get(&my_status_timer) > 0) {
    /* timer has expired */
} else if (k_timer_remaining_get(&my_status_timer) == 0) {
    /* timer was stopped (by someone else) before expiring */
} else {
    /* timer is still running */
}
```

Using Timer Status Synchronization The following code performs timer status synchronization to allow a thread to do useful work while ensuring that a pair of protocol operations are separated by the specified time interval.

```
K_TIMER_DEFINE(my_sync_timer, NULL, NULL);

...

/* do first protocol operation */
...

/* start a one-shot timer that expires after 500 ms */
k_timer_start(&my_sync_timer, K_MSEC(500), K_NO_WAIT);

/* do other work */
...

/* ensure timer has expired (waiting for expiry, if necessary) */
k_timer_status_sync(&my_sync_timer);

/* do second protocol operation */
...
```

Note

If the thread had no other work to do it could simply sleep between the two protocol operations, without using a timer.

Suggested Uses Use a timer to initiate an asynchronous operation after a specified amount of time.

Use a timer to determine whether or not a specified amount of time has elapsed. In particular, timers should be used when higher precision and/or unit control is required than that afforded by the simpler *k_sleep()* and *k_usleep()* calls.

Use a timer to perform other work while carrying out operations involving time limits.

Note

If a thread needs to measure the time required to perform an operation it can read the *system clock or the hardware clock* directly, rather than using a timer.

Configuration Options Related configuration options:

- None

API Reference

group `timer_apis`

Defines

K_TIMER_DEFINE(name, expiry_fn, stop_fn)

Statically define and initialize a timer.

The timer can be accessed outside the module where it is defined using:

```
extern struct k_timer <name>;
```

Parameters

- **name** – Name of the timer variable.
- **expiry_fn** – Function to invoke each time the timer expires.
- **stop_fn** – Function to invoke if the timer is stopped while running.

Typedefs

typedef void (*k_timer_expiry_t)(struct k_timer *timer)

Timer expiry function type.

A timer's expiry function is executed by the system clock interrupt handler each time the timer expires. The expiry function is optional, and is only invoked if the timer has been initialized with one.

Param timer
Address of timer.

typedef void (*k_timer_stop_t)(struct k_timer *timer)

Timer stop function type.

A timer's stop function is executed if the timer is stopped prematurely. The function runs in the context of call that stops the timer. As *k_timer_stop()* can be invoked from an ISR, the stop function must be callable from interrupt context (isr-ok).

The stop function is optional, and is only invoked if the timer has been initialized with one.

Param timer
Address of timer.

Functions

void k_timer_init(struct k_timer *timer, *k_timer_expiry_t* expiry_fn, *k_timer_stop_t* stop_fn)

Initialize a timer.

This routine initializes a timer, prior to its first use.

Parameters

- **timer** – Address of timer.
- **expiry_fn** – Function to invoke each time the timer expires.
- **stop_fn** – Function to invoke if the timer is stopped while running.

void **k_timer_start**(struct k_timer *timer, *k_timeout_t* duration, *k_timeout_t* period)

Start a timer.

This routine starts a timer, and resets its status to zero. The timer begins counting down using the specified duration and period values.

Attempting to start a timer that is already running is permitted. The timer's status is reset to zero and the timer begins counting down using the new duration and period values.

Parameters

- **timer** – Address of timer.
- **duration** – Initial timer duration.
- **period** – Timer period.

void **k_timer_stop**(struct k_timer *timer)

Stop a timer.

This routine stops a running timer prematurely. The timer's stop function, if one exists, is invoked by the caller.

Attempting to stop a timer that is not running is permitted, but has no effect on the timer.

Function properties (list may not be complete)

isr-ok

Note

The stop handler has to be callable from ISRs if *k_timer_stop* is to be called from ISRs.

Parameters

- **timer** – Address of timer.

uint32_t **k_timer_status_get**(struct k_timer *timer)

Read timer status.

This routine reads the timer's status, which indicates the number of times it has expired since its status was last read.

Calling this routine resets the timer's status to zero.

Parameters

- **timer** – Address of timer.

Returns

Timer status.

uint32_t **k_timer_status_sync**(struct k_timer *timer)

Synchronize thread to timer expiration.

This routine blocks the calling thread until the timer's status is non-zero (indicating that it has expired at least once since it was last examined) or the timer is stopped. If the timer status is already non-zero, or the timer is already stopped, the caller continues without waiting.

Calling this routine resets the timer's status to zero.

This routine must not be used by interrupt handlers, since they are not allowed to block.

Parameters

- **timer** – Address of timer.

Returns
Timer status.

k_ticks_t **k_timer_expires_ticks**(const struct k_timer *timer)

Get next expiration time of a timer, in system ticks.

This routine returns the future system uptime reached at the next time of expiration of the timer, in units of system ticks. If the timer is not running, current system time is returned.

Parameters

- **timer** – The timer object

Returns
Uptime of expiration, in ticks

k_ticks_t **k_timer_remaining_ticks**(const struct k_timer *timer)

Get time remaining before a timer next expires, in system ticks.

This routine computes the time remaining before a running timer next expires, in units of system ticks. If the timer is not running, it returns zero.

Parameters

- **timer** – The timer object

Returns
Remaining time until expiration, in ticks

static inline uint32_t **k_timer_remaining_get**(struct k_timer *timer)

Get time remaining before a timer next expires.

This routine computes the (approximate) time remaining before a running timer next expires. If the timer is not running, it returns zero.

Parameters

- **timer** – Address of timer.

Returns
Remaining time (in milliseconds).

void **k_timer_user_data_set**(struct k_timer *timer, void *user_data)

Associate user-specific data with a timer.

This routine records the *user_data* with the *timer*, to be retrieved later.

It can be used e.g. in a timer handler shared across multiple subsystems to retrieve data specific to the subsystem this timer is associated with.

Parameters

- **timer** – Address of timer.
- **user_data** – User data to associate with the timer.

void ***k_timer_user_data_get**(const struct k_timer *timer)

Retrieve the user-specific data from a timer.

Parameters

- **timer** – Address of timer.

Returns
The user data.

3.1.5 Other

These pages cover other kernel services.

Atomic Services

An *atomic variable* is one that can be read and modified by threads and ISRs in an uninterruptible manner. It is a 32-bit variable on 32-bit machines and a 64-bit variable on 64-bit machines.

- *Concepts*
- *Implementation*
  - *Defining an Atomic Variable*
  - *Manipulating an Atomic Variable*
  - *Manipulating an Array of Atomic Variables*
  - *Memory Ordering*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of atomic variables can be defined (limited only by available RAM).

Using the kernel's atomic APIs to manipulate an atomic variable guarantees that the desired operation occurs correctly, even if higher priority contexts also manipulate the same variable.

The kernel also supports the atomic manipulation of a single bit in an array of atomic variables.

Implementation

Defining an Atomic Variable An atomic variable is defined using a variable of type `atomic_t`.

By default an atomic variable is initialized to zero. However, it can be given a different value using *ATOMIC_INIT*:

```
atomic_t flags = ATOMIC_INIT(0xFF);
```

Manipulating an Atomic Variable An atomic variable is manipulated using the APIs listed at the end of this section.

The following code shows how an atomic variable can be used to keep track of the number of times a function has been invoked. Since the count is incremented atomically, there is no risk that it will become corrupted in mid-increment if a thread calling the function is interrupted if by a higher priority context that also calls the routine.

```
atomic_t call_count;

int call_counting_routine(void)
{
    /* increment invocation counter */
    atomic_inc(&call_count);

    /* do rest of routine's processing */
    ...
}
```

Manipulating an Array of Atomic Variables An array of 32-bit atomic variables can be defined in the conventional manner. However, you can also define an N-bit array of atomic variables using *ATOMIC_DEFINE*.

A single bit in array of atomic variables can be manipulated using the APIs listed at the end of this section that end with `_bit()`.

The following code shows how a set of 200 flag bits can be implemented using an array of atomic variables.

```
#define NUM_FLAG_BITS 200

ATOMIC_DEFINE(flag_bits, NUM_FLAG_BITS);

/* set specified flag bit & return its previous value */
int set_flag_bit(int bit_position)
{
    return (int)atomic_set_bit(flag_bits, bit_position);
}
```

Memory Ordering For consistency and correctness, all Zephyr atomic APIs are expected to include a full memory barrier (in the sense of e.g. "serializing" instructions on x86, "DMB" on ARM, or a "sequentially consistent" operation as defined by the C++ memory model) where needed by hardware to guarantee a reliable picture across contexts. Any architecture-specific implementations are responsible for ensuring this behavior.

Suggested Uses Use an atomic variable to implement critical section processing that only requires the manipulation of a single 32-bit value.

Use multiple atomic variables to implement critical section processing on a set of flag bits in a bit array longer than 32 bits.

Note

Using atomic variables is typically far more efficient than using other techniques to implement critical sections such as using a mutex or locking interrupts.

Configuration Options Related configuration options:

- `CONFIG_ATOMIC_OPERATIONS_BUILTIN`
- `CONFIG_ATOMIC_OPERATIONS_ARCH`
- `CONFIG_ATOMIC_OPERATIONS_C`

Important

All atomic services APIs can be used by both threads and ISRs.

API Reference

group `atomic_apis`

Defines

`ATOMIC_INIT`(i)

Initialize an atomic variable.

This macro can be used to initialize an atomic variable. For example,

```
atomic_t my_var = ATOMIC_INIT(75);
```

Parameters

- `i` – Value to assign to atomic variable.

`ATOMIC_PTR_INIT`(p)

Initialize an atomic pointer variable.

This macro can be used to initialize an atomic pointer variable. For example,

```
atomic_ptr_t my_ptr = ATOMIC_PTR_INIT(&data);
```

Parameters

- `p` – Pointer value to assign to atomic pointer variable.

`ATOMIC_BITMAP_SIZE`(num_bits)

This macro computes the number of atomic variables necessary to represent a bitmap with *num_bits*.

Parameters

- `num_bits` – Number of bits.

`ATOMIC_DEFINE`(name, num_bits)

Define an array of atomic variables.

This macro defines an array of atomic variables containing at least *num_bits* bits.

Note

If used from file scope, the bits of the array are initialized to zero; if used from within a function, the bits are left uninitialized.

Parameters

- `name` – Name of array of atomic variables.
- `num_bits` – Number of bits needed.

Functions

static inline bool **atomic_test_bit**(const atomic_t *target, int bit)

Atomically test a bit.

This routine tests whether bit number *bit* of *target* is set or not. The target may be a single atomic variable or an array of them.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable or array.
- **bit** – Bit number (starting from 0).

Returns

true if the bit was set, false if it wasn't.

static inline bool **atomic_test_and_clear_bit**(atomic_t *target, int bit)

Atomically test and clear a bit.

Atomically clear bit number *bit* of *target* and return its old value. The target may be a single atomic variable or an array of them.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable or array.
- **bit** – Bit number (starting from 0).

Returns

false if the bit was already cleared, true if it wasn't.

static inline bool **atomic_test_and_set_bit**(atomic_t *target, int bit)

Atomically set a bit.

Atomically set bit number *bit* of *target* and return its old value. The target may be a single atomic variable or an array of them.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable or array.
- **bit** – Bit number (starting from 0).

Returns
true if the bit was already set, false if it wasn't.

static inline void **atomic_clear_bit**(atomic_t *target, int bit)

Atomically clear a bit.

Atomically clear bit number *bit* of *target*. The target may be a single atomic variable or an array of them.

> **Note**
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable or array.
- **bit** – Bit number (starting from 0).

static inline void **atomic_set_bit**(atomic_t *target, int bit)

Atomically set a bit.

Atomically set bit number *bit* of *target*. The target may be a single atomic variable or an array of them.

> **Note**
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable or array.
- **bit** – Bit number (starting from 0).

static inline void **atomic_set_bit_to**(atomic_t *target, int bit, bool val)

Atomically set a bit to a given value.

Atomically set bit number *bit* of *target* to value *val*. The target may be a single atomic variable or an array of them.

> **Note**
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable or array.
- **bit** – Bit number (starting from 0).
- **val** – true for 1, false for 0.

bool **atomic_cas**(atomic_t *target, atomic_val_t old_value, atomic_val_t new_value)

Atomic compare-and-set.

This routine performs an atomic compare-and-set on *target*. If the current value of *target* equals *old_value*, *target* is set to *new_value*. If the current value of *target* does not equal *old_value*, *target* is left unchanged.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable.
- **old_value** – Original value to compare against.
- **new_value** – New value to store.

Returns

true if *new_value* is written, false otherwise.

bool **atomic_ptr_cas**(atomic_ptr_t *target, atomic_ptr_val_t old_value, atomic_ptr_val_t new_value)

Atomic compare-and-set with pointer values.

This routine performs an atomic compare-and-set on *target*. If the current value of *target* equals *old_value*, *target* is set to *new_value*. If the current value of *target* does not equal *old_value*, *target* is left unchanged.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable.
- **old_value** – Original value to compare against.
- **new_value** – New value to store.

Returns

true if *new_value* is written, false otherwise.

atomic_val_t **atomic_add**(atomic_t *target, atomic_val_t value)

Atomic addition.

This routine performs an atomic addition on *target*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable.

- **value** – Value to add.

Returns
Previous value of *target*.

atomic_val_t **atomic_sub**(atomic_t *target, atomic_val_t value)

Atomic subtraction.

This routine performs an atomic subtraction on *target*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable.
- **value** – Value to subtract.

Returns
Previous value of *target*.

atomic_val_t **atomic_inc**(atomic_t *target)

Atomic increment.

This routine performs an atomic increment by 1 on *target*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable.

Returns
Previous value of *target*.

atomic_val_t **atomic_dec**(atomic_t *target)

Atomic decrement.

This routine performs an atomic decrement by 1 on *target*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable.

Returns
Previous value of *target*.

atomic_val_t **atomic_get**(const atomic_t *target)

Atomic get.

This routine performs an atomic read on *target*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable.

Returns

Value of *target*.

atomic_ptr_val_t **atomic_ptr_get**(const atomic_ptr_t *target)

Atomic get a pointer value.

This routine performs an atomic read on *target*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of pointer variable.

Returns

Value of *target*.

atomic_val_t **atomic_set**(atomic_t *target, atomic_val_t value)

Atomic get-and-set.

This routine atomically sets *target* to *value* and returns the previous value of *target*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable.
- **value** – Value to write to *target*.

Returns

Previous value of *target*.

atomic_ptr_val_t **atomic_ptr_set**(atomic_ptr_t *target, atomic_ptr_val_t value)

Atomic get-and-set for pointer values.

This routine atomically sets *target* to *value* and returns the previous value of *target*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- `target` – Address of atomic variable.
- `value` – Value to write to *target*.

Returns
Previous value of *target*.

atomic_val_t **atomic_clear**(atomic_t *target)

Atomic clear.

This routine atomically sets *target* to zero and returns its previous value. (Hence, it is equivalent to atomic_set(target, 0).)

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- `target` – Address of atomic variable.

Returns
Previous value of *target*.

atomic_ptr_val_t **atomic_ptr_clear**(atomic_ptr_t *target)

Atomic clear of a pointer value.

This routine atomically sets *target* to zero and returns its previous value. (Hence, it is equivalent to atomic_set(target, 0).)

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- `target` – Address of atomic variable.

Returns
Previous value of *target*.

atomic_val_t **atomic_or**(atomic_t *target, atomic_val_t value)

Atomic bitwise inclusive OR.

This routine atomically sets *target* to the bitwise inclusive OR of *target* and *value*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- `target` – Address of atomic variable.
- `value` – Value to OR.

Returns
Previous value of *target*.

atomic_val_t **atomic_xor**(atomic_t *target, atomic_val_t value)

Atomic bitwise exclusive OR (XOR).

This routine atomically sets *target* to the bitwise exclusive OR (XOR) of *target* and *value*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- `target` – Address of atomic variable.
- `value` – Value to XOR

Returns
Previous value of *target*.

atomic_val_t **atomic_and**(atomic_t *target, atomic_val_t value)

Atomic bitwise AND.

This routine atomically sets *target* to the bitwise AND of *target* and *value*.

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- `target` – Address of atomic variable.
- `value` – Value to AND.

Returns
Previous value of *target*.

atomic_val_t **atomic_nand**(atomic_t *target, atomic_val_t value)

Atomic bitwise NAND.

This routine atomically sets *target* to the bitwise NAND of *target* and *value*. (This operation is equivalent to target = ~(target & value).)

> **Note**
>
> As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- `target` – Address of atomic variable.
- `value` – Value to NAND.

Returns
Previous value of *target*.

Floating Point Services

The kernel allows threads to use floating point registers on board configurations that support these registers.

> **Note**
>
> Floating point services are currently available only for boards based on ARM Cortex-M SoCs supporting the Floating Point Extension, the Intel x86 architecture, the SPARC architecture and ARCv2 SoCs supporting the Floating Point Extension. The services provided are architecture specific.
>
> The kernel does not support the use of floating point registers by ISRs.

- *Concepts*
  - *No FP registers mode*
  - *Unshared FP registers mode*
  - *Shared FP registers mode*
- *Implementation*
  - *Performing Floating Point Arithmetic*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts The kernel can be configured to provide only the floating point services required by an application. Three modes of operation are supported, which are described below. In addition, the kernel's support for the SSE registers can be included or omitted, as desired.

No FP registers mode This mode is used when the application has no threads that use floating point registers. It is the kernel's default floating point services mode.

If a thread uses any floating point register, the kernel generates a fatal error condition and aborts the thread.

Unshared FP registers mode This mode is used when the application has only a single thread that uses floating point registers.

On x86 platforms, the kernel initializes the floating point registers so they can be used by any thread (initialization in skipped on ARM Cortex-M platforms and ARCv2 platforms). The floating point registers are left unchanged whenever a context switch occurs.

> **Note**
>
> The behavior is undefined, if two or more threads attempt to use the floating point registers, as the kernel does not attempt to detect (or prevent) multiple threads from using these registers.

Shared FP registers mode This mode is used when the application has two or more threads that use floating point registers. Depending upon the underlying CPU architecture, the kernel supports one or more of the following thread sub-classes:

- non-user: A thread that cannot use any floating point registers
- FPU user: A thread that can use the standard floating point registers
- SSE user: A thread that can use both the standard floating point registers and SSE registers

The kernel initializes and enables access to the floating point registers, so they can be used by any thread, then saves and restores these registers during context switches to ensure the computations performed by each FPU user or SSE user are not impacted by the computations performed by the other users.

> **Note**
>
> The Shared FP registers mode is the default Floating Point Services mode in ARM Cortex-M.

ARM Cortex-M architecture (with the Floating Point Extension) On the ARM Cortex-M architecture with the Floating Point Extension, the kernel treats *all* threads as FPU users when shared FP registers mode is enabled. This means that any thread is allowed to access the floating point registers. The ARM kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them.

Pretag a thread that intends to use the FP registers by using one of the techniques listed below.

- A statically-created ARM thread can be pretagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created ARM thread can be pretagged by passing the `K_FP_REGS` option to `k_thread_create()`.

Pretagging a thread with the `K_FP_REGS` option instructs the MPU-based stack protection mechanism to properly configure the size of the thread's guard region to always guarantee stack overflow detection, and enable lazy stacking for the given thread upon thread creation.

During thread context switching the ARM kernel saves the *callee-saved* floating point registers, if the switched-out thread has been using them. Additionally, the *caller-saved* floating point registers are saved on the thread's stack. If the switched-in thread has been using the floating point registers, the kernel restores the *callee-saved* FP registers of the switched-in thread and the *caller-saved* FP context is restored from the thread's stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers.

Each thread that intends to use the floating point registers must provide an extra 72 bytes of stack space where the callee-saved FP context can be saved.

Lazy Stacking is currently enabled in Zephyr applications on ARM Cortex-M architecture, minimizing interrupt latency, when the floating point context is active.

When the MPU-based stack protection mechanism is not enabled, lazy stacking is always active in the Zephyr application. When the MPU-based stack protection is enabled, the following rules apply with respect to lazy stacking:

- Lazy stacking is activated by default on threads that are pretagged with *K_FP_REGS*
- Lazy stacking is activated dynamically on threads that are not pretagged with *K_FP_REGS*, as soon as the kernel detects that they are using the floating point registers.

If an ARM thread does not require use of the floating point registers any more, it can call *k_float_disable()*. This instructs the kernel not to save or restore its FP context during thread context switching.

Note

The Shared FP registers mode is the default Floating Point Services mode on ARM64. The compiler is free to optimize code using FP/SIMD registers, and library functions such as memcpy are known to make use of them.

ARM64 architecture On the ARM64 (Aarch64) architecture the kernel treats each thread as a FPU user on a case-by-case basis. A "lazy save" algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are *not* saved when switching from an FPU user to a non-user thread, and then back to the original FPU user.

FPU register usage by ISRs is supported although not recommended. When an ISR uses floating point or SIMD registers, then the access is trapped, the current FPU user context is saved in the thread object and the ISR is resumed with interrupts disabled so to prevent another IRQ from interrupting the ISR and potentially requesting FPU usage. Because ISR don't have a persistent register context, there are no provision for saving an ISR's FPU context either, hence the IRQ disabling.

Each thread object becomes 512 bytes larger when Shared FP registers mode is enabled.

ARCv2 architecture On the ARCv2 architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques.

- A statically-created ARC thread can be tagged by passing the *K_FP_REGS* option to *K_THREAD_DEFINE*.
- A dynamically-created ARC thread can be tagged by passing the *K_FP_REGS* to *k_thread_create()*.

If an ARC thread does not require use of the floating point registers any more, it can call *k_float_disable()*. This instructs the kernel not to save or restore its FP context during thread context switching.

During thread context switching the ARC kernel saves the *callee-saved* floating point registers, if the switched-out thread has been using them. Additionally, the *caller-saved* floating point registers are saved on the thread's stack. If the switched-in thread has been using the floating point registers, the kernel restores the *callee-saved* FP registers of the switched-in thread and the *caller-saved* FP context is restored from the thread's stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers. An extra 16 bytes (single floating point hardware) or 32 bytes (double floating point hardware) of stack space is required to load and store floating point registers.

RISC-V architecture On the RISC-V architecture the kernel treats each thread as an FPU user on a case-by-case basis with the FPU access allocated on demand. A "lazy save" algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the FPU registers are *not* saved when switching from an FPU user to a non-user thread (or an FPU user that doesn't touch the FPU during its scheduling slot), and then back to the original FPU user.

FPU register usage by ISRs is supported although not recommended. When an ISR uses floating point or SIMD registers, then the access is trapped, the current FPU user context is saved in the thread object and the ISR is resumed with interrupts disabled so to prevent another IRQ from interrupting the ISR and potentially requesting FPU usage. Because ISR don't have a persistent register context, there are no provision for saving an ISR's FPU context either, hence the IRQ disabling.

As an optimization, the FPU context is preemptively restored upon scheduling back an "active FPU user" thread that had its FPU context saved away due to FPU usage by another thread. Active FPU users are so designated when they make the FPU state "dirty" during their most recent scheduling slot before being scheduled out. So if a thread doesn't modify the FPU state within its scheduling slot and another thread claims the FPU for itself afterwards then that first thread will be subjected to the on-demand regime and won't have its FPU context restored until it attempts to access it again. But if that thread does modify the FPU before being scheduled out then it is likely to continue using it when scheduled back in and preemptively restoring its FPU context saves on the exception trap overhead that would occur otherwise.

Each thread object becomes 136 bytes (single-precision floating point hardware) or 264 bytes (double-precision floating point hardware) larger when Shared FP registers mode is enabled.

SPARC architecture On the SPARC architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques:

- A statically-created thread can be tagged by passing the *K_FP_REGS* option to *K_THREAD_DEFINE*.
- A dynamically-created thread can be tagged by passing the *K_FP_REGS* to *k_thread_create()*.

During thread context switch at exit from interrupt handler, the SPARC kernel saves *all* floating point registers, if the FPU was enabled in the switched-out thread. Floating point registers are saved on the thread's stack. Floating point registers are restored when a thread context is restored iff they were saved at the context save. Saving and restoring of the floating point registers is synchronous and thus not lazy. The FPU is always disabled when an ISR is called (independent of CONFIG_FPU_SHARING).

Floating point disabling with *k_float_disable()* is not implemented.

When CONFIG_FPU_SHARING is used, then 136 bytes of stack space is required for each FPU user thread to load and store floating point registers. No extra stack is required if CONFIG_FPU_SHARING is not used.

x86 architecture On the x86 architecture the kernel treats each thread as a non-user, FPU user or SSE user on a case-by-case basis. A "lazy save" algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are *not* saved when switching from an FPU user to a non-user thread, and then back to the original FPU user. The following table indicates the amount of additional stack space a thread must provide so the registers can be saved properly.

Thread type	FP register use	Extra stack space required
cooperative	any	0 bytes
preemptive	none	0 bytes
preemptive	FPU	108 bytes
preemptive	SSE	464 bytes

The x86 kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them. The thread is tagged as an SSE user if the kernel has been configured to support the SSE registers, or as an FPU user if the SSE registers are not supported. If this would result in a thread that is an FPU user being tagged as an SSE user, or if the application wants to avoid the exception handling overhead involved in auto-tagging threads, it is possible to pretag a thread using one of the techniques listed below.

- A statically-created x86 thread can be pretagged by passing the *K_FP_REGS* or *K_SSE_REGS* option to *K_THREAD_DEFINE*.
- A dynamically-created x86 thread can be pretagged by passing the *K_FP_REGS* or *K_SSE_REGS* option to *k_thread_create()*.
- An already-created x86 thread can pretag itself once it has started by passing the *K_FP_REGS* or *K_SSE_REGS* option to *k_float_enable()*.

If an x86 thread uses the floating point registers infrequently it can call *k_float_disable()* to remove its tagging as an FPU user or SSE user. This eliminates the need for the kernel to take steps to preserve the contents of the floating point registers during context switches when there is no need to do so. When the thread again needs to use the floating point registers it can re-tag itself as an FPU user or SSE user by calling *k_float_enable()*.

Implementation

Performing Floating Point Arithmetic No special coding is required for a thread to use floating point arithmetic if the kernel is properly configured.

The following code shows how a routine can use floating point arithmetic to avoid overflow issues when computing the average of a series of integer values.

```
int average(int *values, int num_values)
{
    double sum;
    int i;

    sum = 0.0;

    for (i = 0; i < num_values; i++) {
        sum += *values;
        values++;
    }

    return (int)((sum / num_values) + 0.5);
}
```

Suggested Uses Use the kernel floating point services when an application needs to perform floating point operations.

Configuration Options To configure unshared FP registers mode, enable the CONFIG_FPU configuration option and leave the CONFIG_FPU_SHARING configuration option disabled.

To configure shared FP registers mode, enable both the CONFIG_FPU configuration option and the CONFIG_FPU_SHARING configuration option. Also, ensure that any thread that uses the floating point registers has sufficient added stack space for saving floating point register values during context switches, as described above.

For x86, use the CONFIG_X86_SSE configuration option to enable support for SSEx instructions.

API Reference

group `float_apis`

Functions

int `k_float_disable`(struct *k_thread* *thread)

Disable preservation of floating point context information.

This routine informs the kernel that the specified thread will no longer be using the floating point registers.

Warning

Some architectures apply restrictions on how the disabling of floating point preservation may be requested, see arch_float_disable.

Warning

This routine should only be used to disable floating point support for a thread that currently has such support enabled.

Parameters

- `thread` – ID of thread.

Return values

- `0` – On success.
- `-ENOTSUP` – If the floating point disabling is not implemented. -EINVAL If the floating point disabling could not be performed.

int `k_float_enable`(struct *k_thread* *thread, unsigned int options)

Enable preservation of floating point context information.

This routine informs the kernel that the specified thread will use the floating point registers.

Invoking this routine initializes the thread's floating point context info to that of an FPU that has been reset. The next time the thread is scheduled by z_swap() it will either inherit an FPU that is guaranteed to be in a "sane" state (if the most recent user of the FPU was cooperatively swapped out) or the thread's own floating point context will be loaded (if the most recent user of the FPU was preempted, or if this thread is the first user of the FPU). Thereafter, the kernel will protect the thread's FP context so that it is not altered during a preemptive context switch.

The *options* parameter indicates which floating point register sets will be used by the specified thread.

For x86 options:

- K_FP_REGS indicates x87 FPU and MMX registers only
- K_SSE_REGS indicates SSE registers (and also x87 FPU and MMX registers)

Warning

Some architectures apply restrictions on how the enabling of floating point preservation may be requested, see arch_float_enable.

Warning

This routine should only be used to enable floating point support for a thread that currently has such support enabled.

Parameters

- `thread` – ID of thread.
- `options` – architecture dependent options

Return values

- `0` – On success.
- `-ENOTSUP` – If the floating point enabling is not implemented. -EINVAL If the floating point enabling could not be performed.

Version

Kernel version handling and APIs related to kernel version being used.

API Reference

uint32_t `sys_kernel_version_get`(void)

Return the kernel version of the present build.

The kernel version is a four-byte value, whose format is described in the file "kernel_version.h".

Returns

kernel version

`SYS_KERNEL_VER_MAJOR`(ver)

`SYS_KERNEL_VER_MINOR`(ver)

`SYS_KERNEL_VER_PATCHLEVEL`(ver)

Fatal Errors

Software Errors Triggered in Source Code Zephyr provides several methods for inducing fatal error conditions through either build-time checks, conditionally compiled assertions, or deliberately invoked panic or oops conditions.

Runtime Assertions Zephyr provides some macros to perform runtime assertions which may be conditionally compiled. Their definitions may be found in include/zephyr/sys/__assert.h.

Assertions are enabled by setting the `__ASSERT_ON` preprocessor symbol to a non-zero value. There are two ways to do this:

- Use the `CONFIG_ASSERT` and `CONFIG_ASSERT_LEVEL` kconfig options.
- Add `-D__ASSERT_ON=<level>` to the project's CFLAGS, either on the build command line or in a CMakeLists.txt.

The `__ASSERT_ON` method takes precedence over the kconfig option if both are used.

Specifying an assertion level of 1 causes the compiler to issue warnings that the kernel contains debug-type `__ASSERT()` statements; this reminder is issued since assertion code is not normally present in a final product. Specifying assertion level 2 suppresses these warnings.

Assertions are enabled by default when running Zephyr test cases, as configured by the `CONFIG_TEST` option.

The policy for what to do when encountering a failed assertion is controlled by the implementation of `assert_post_action()`. Zephyr provides a default implementation with weak linkage which invokes a kernel oops if the thread that failed the assertion was running in user mode, and a kernel panic otherwise.

__ASSERT() The `__ASSERT()` macro can be used inside kernel and application code to perform optional runtime checks which will induce a fatal error if the check does not pass. The macro takes a string message which will be printed to provide context to the assertion. In addition, the kernel will print a text representation of the expression code that was evaluated, and the file and line number where the assertion can be found.

For example:

```
__ASSERT(foo == 0xF0CACC1A, "Invalid value of foo, got 0x%x", foo);
```

If at runtime `foo` had some unexpected value, the error produced may look like the following:

```
ASSERTION FAIL [foo == 0xF0CACC1A] @ ZEPHYR_BASE/tests/kernel/fatal/src/main.c:367
        Invalid value of foo, got 0xdeadbeef
[00:00:00.000,000] <err> os: r0/a1:  0x00000004  r1/a2:  0x0000016f  r2/a3:  0x00000000
[00:00:00.000,000] <err> os: r3/a4:  0x00000000 r12/ip:  0x00000000 r14/lr:  0x00000a6d
[00:00:00.000,000] <err> os:  xpsr:  0x61000000
[00:00:00.000,000] <err> os: Faulting instruction address (r15/pc): 0x00009fe4
[00:00:00.000,000] <err> os: >>> ZEPHYR FATAL ERROR 4: Kernel panic
[00:00:00.000,000] <err> os: Current thread: 0x20000414 (main)
[00:00:00.000,000] <err> os: Halting system
```

__ASSERT_EVAL() The `__ASSERT_EVAL()` macro can also be used inside kernel and application code, with special semantics for the evaluation of its arguments.

It makes use of the `__ASSERT()` macro, but has some extra flexibility. It allows the developer to specify different actions depending whether the `__ASSERT()` macro is enabled or not. This can be particularly useful to prevent the compiler from generating comments (errors, warnings or remarks) about variables that are only used with `__ASSERT()` being assigned a value, but otherwise unused when the `__ASSERT()` macro is disabled.

Consider the following example:

```
int x;
x = foo();
__ASSERT(x != 0, "foo() returned zero!");
```

If __ASSERT() is disabled, then 'x' is assigned a value, but never used. This type of situation can be resolved using the __ASSERT_EVAL() macro.

```
__ASSERT_EVAL ((void) foo(),
               int x = foo(),
               x != 0,
               "foo() returned zero!");
```

The first parameter tells __ASSERT_EVAL() what to do if __ASSERT() is disabled. The second parameter tells __ASSERT_EVAL() what to do if __ASSERT() is enabled. The third and fourth parameters are the parameters it passes to __ASSERT().

__ASSERT_NO_MSG() The __ASSERT_NO_MSG() macro can be used to perform an assertion that reports the failed test and its location, but lacks additional debugging information provided to assist the user in diagnosing the problem; its use is discouraged.

Build Assertions Zephyr provides two macros for performing build-time assertion checks. These are evaluated completely at compile-time, and are always checked.

BUILD_ASSERT() This has the same semantics as C's _Static_assert or C++'s static_assert. If the evaluation fails, a build error will be generated by the compiler. If the compiler supports it, the provided message will be printed to provide further context.

Unlike __ASSERT(), the message must be a static string, without printf()-like format codes or extra arguments.

For example, suppose this check fails:

```
BUILD_ASSERT(FOO == 2000, "Invalid value of FOO");
```

With GCC, the output resembles:

```
tests/kernel/fatal/src/main.c: In function 'test_main':
include/toolchain/gcc.h:28:37: error: static assertion failed: "Invalid value of FOO"
 #define BUILD_ASSERT(EXPR, MSG) _Static_assert(EXPR, "" MSG)
                                 ^~~~~~~~~~~~~~
tests/kernel/fatal/src/main.c:370:2: note: in expansion of macro 'BUILD_ASSERT'
  BUILD_ASSERT(FOO == 2000,
  ^~~~~~~~~~~~~~~~
```

Kernel Oops A kernel oops is a software triggered fatal error invoked by k_oops(). This should be used to indicate an unrecoverable condition in application logic.

The fatal error reason code generated will be K_ERR_KERNEL_OOPS.

Kernel Panic A kernel error is a software triggered fatal error invoked by k_panic(). This should be used to indicate that the Zephyr kernel is in an unrecoverable state. Implementations of *k_sys_fatal_error_handler()* should not return if the kernel encounters a panic condition, as the entire system needs to be reset.

Threads running in user mode are not permitted to invoke k_panic(), and doing so will generate a kernel oops instead. Otherwise, the fatal error reason code generated will be K_ERR_KERNEL_PANIC.

Exceptions

Spurious Interrupts If the CPU receives a hardware interrupt on an interrupt line that has not had a handler installed with IRQ_CONNECT() or *irq_connect_dynamic()*, then the kernel will generate a fatal error with the reason code K_ERR_SPURIOUS_IRQ().

Stack Overflows In the event that a thread pushes more data onto its execution stack than its stack buffer provides, the kernel may be able to detect this situation and generate a fatal error with a reason code of K_ERR_STACK_CHK_FAIL.

If a thread is running in user mode, then stack overflows are always caught, as the thread will simply not have permission to write to adjacent memory addresses outside of the stack buffer. Because this is enforced by the memory protection hardware, there is no risk of data corruption to memory that the thread would not otherwise be able to write to.

If a thread is running in supervisor mode, or if CONFIG_USERSPACE is not enabled, depending on configuration stack overflows may or may not be caught. CONFIG_HW_STACK_PROTECTION is supported on some architectures and will catch stack overflows in supervisor mode, including when handling a system call on behalf of a user thread. Typically this is implemented via dedicated CPU features, or read-only MMU/MPU guard regions placed immediately adjacent to the stack buffer. Stack overflows caught in this way can detect the overflow, but cannot guarantee against data corruption and should be treated as a very serious condition impacting the health of the entire system.

If a platform lacks memory management hardware support, CONFIG_STACK_SENTINEL is a software-only stack overflow detection feature which periodically checks if a sentinel value at the end of the stack buffer has been corrupted. It does not require hardware support, but provides no protection against data corruption. Since the checks are typically done at interrupt exit, the overflow may be detected a nontrivial amount of time after the stack actually overflowed.

Finally, Zephyr supports GCC compiler stack canaries via CONFIG_STACK_CANARIES. If enabled, the compiler will insert a canary value randomly generated at boot into function stack frames, checking that the canary has not been overwritten at function exit. If the check fails, the compiler invokes __stack_chk_fail(), whose Zephyr implementation invokes a fatal stack overflow error. An error in this case does not indicate that the entire stack buffer has overflowed, but instead that the current function stack frame has been corrupted. See the compiler documentation for more details.

Other Exceptions Any other type of unhandled CPU exception will generate an error code of K_ERR_CPU_EXCEPTION.

Fatal Error Handling The policy for what to do when encountering a fatal error is determined by the implementation of the *k_sys_fatal_error_handler()* function. This function has a default implementation with weak linkage that calls LOG_PANIC() to dump all pending logging messages and then unconditionally halts the system with *k_fatal_halt()*.

Applications are free to implement their own error handling policy by overriding the implementation of *k_sys_fatal_error_handler()*. If the implementation returns, the faulting thread will be aborted and the system will otherwise continue to function. See the documentation for this function for additional details and constraints.

API Reference

group fatal_apis

Functions

FUNC_NORETURN void **k_fatal_halt**(unsigned int reason)

Halt the system on a fatal error.

Invokes architecture-specific code to power off or halt the system in a low power state. Lacking that, lock interrupts and sit in an idle loop.

Parameters

- **reason** – Fatal exception reason code

void **k_sys_fatal_error_handler**(unsigned int reason, const struct arch_esf *esf)

Fatal error policy handler.

This function is not invoked by application code, but is declared as a weak symbol so that applications may introduce their own policy.

The default implementation of this function halts the system unconditionally. Depending on architecture support, this may be a simple infinite loop, power off the hardware, or exit an emulator.

If this function returns, then the currently executing thread will be aborted.

A few notes for custom implementations:

- If the error is determined to be unrecoverable, *LOG_PANIC()* should be invoked to flush any pending logging buffers.
- K_ERR_KERNEL_PANIC indicates a severe unrecoverable error in the kernel itself, and should not be considered recoverable. There is an assertion in z_fatal_error() to enforce this.
- Even outside of a kernel panic, unless the fault occurred in user mode, the kernel itself may be in an inconsistent state, with API calls to kernel objects possibly exhibiting undefined behavior or triggering another exception.

Parameters

- **reason** – The reason for the fatal error
- **esf** – Exception context, with details and partial or full register state when the error occurred. May in some cases be NULL.

Thread Local Storage (TLS)

Thread Local Storage (TLS) allows variables to be allocated on a per-thread basis. These variables are stored in the thread stack which means every thread has its own copy of these variables.

Zephyr currently requires toolchain support for TLS.

Configuration To enable thread local storage in Zephyr, `CONFIG_THREAD_LOCAL_STORAGE` needs to be enabled. Note that this option may not be available if the architecture or the SoC does not have the hidden option `CONFIG_ARCH_HAS_THREAD_LOCAL_STORAGE` enabled, which means the architecture or the SoC does not have the necessary code to support thread local storage and/or the toolchain does not support TLS.

`CONFIG_ERRNO_IN_TLS` can be enabled together with `CONFIG_ERRNO` to let the variable `errno` be a thread local variable. This allows user threads to access the value of `errno` without making a system call.

Declaring and Using Thread Local Variables The keyword `__thread` can be used to declare thread local variables.

For example, to declare a thread local variable in header files:

```
extern __thread int i;
```

And to declare the actual variable in source files:

```
__thread int i;
```

Keyword `static` can also be used to limit the variable within a source file:

```
static __thread int j;
```

Using the thread local variable is the same as using other variable, for example:

```
void testing(void) {
    i = 10;
}
```

3.2 Device Driver Model

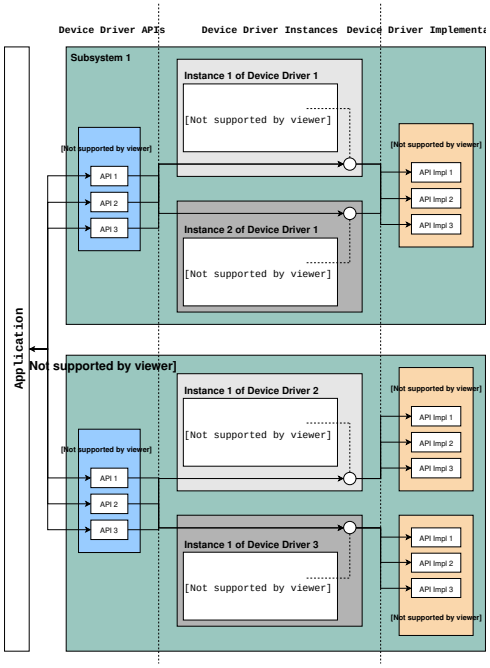
3.2.1 Introduction

The Zephyr kernel supports a variety of device drivers. Whether a driver is available depends on the board and the driver.

The Zephyr device model provides a consistent device model for configuring the drivers that are part of a system. The device model is responsible for initializing all the drivers configured into the system.

Each type of driver (e.g. UART, SPI, I2C) is supported by a generic type API.

In this model the driver fills in the pointer to the structure containing the function pointers to its API functions during driver initialization. These structures are placed into the RAM section in initialization level order.



3.2.2 Standard Drivers

Device drivers which are present on all supported board configurations are listed below.

- **Interrupt controller**: This device driver is used by the kernel's interrupt management subsystem.
- **Timer**: This device driver is used by the kernel's system clock and hardware clock subsystem.
- **Serial communication**: This device driver is used by the kernel's system console subsystem.
- **Entropy**: This device driver provides a source of entropy numbers for the random number generator subsystem.

> **Important**
>
> Use the *random API functions* for random values. *Entropy functions* should not be directly used as a random number generator source as some hardware implementations are designed to be an entropy seed source for random number generators and will not provide cryptographically secure random number streams.

3.2.3 Synchronous Calls

Zephyr provides a set of device drivers for multiple boards. Each driver should support an interrupt-based implementation, rather than polling, unless the specific hardware does not provide any interrupt.

High-level calls accessed through device-specific APIs, such as `i2c.h` or `spi.h`, are usually intended as synchronous. Thus, these calls should be blocking.

3.2.4 Driver APIs

The following APIs for device drivers are provided by `device.h`. The APIs are intended for use in device drivers only and should not be used in applications.

DEVICE_DEFINE()
: Create device object and related data structures including setting it up for boot-time initialization.

DEVICE_NAME_GET()
: Converts a device identifier to the global identifier for a device object.

DEVICE_GET()
: Obtain a pointer to a device object by name.

DEVICE_DECLARE()
: Declare a device object. Use this when you need a forward reference to a device that has not yet been defined.

3.2.5 Driver Data Structures

The device initialization macros populate some data structures at build time which are split into read-only and runtime-mutable parts. At a high level we have:

```
struct device {
      const char *name;
      const void *config;
      const void *api;
      void * const data;
};
```

The `config` member is for read-only configuration data set at build time. For example, base memory mapped IO addresses, IRQ line numbers, or other fixed physical characteristics of the device. This is the `config` pointer passed to `DEVICE_DEFINE()` and related macros.

The `data` struct is kept in RAM, and is used by the driver for per-instance runtime housekeeping. For example, it may contain reference counts, semaphores, scratch buffers, etc.

The `api` struct maps generic subsystem APIs to the device-specific implementations in the driver. It is typically read-only and populated at build time. The next section describes this in more detail.

3.2.6 Subsystems and API Structures

Most drivers will be implementing a device-independent subsystem API. Applications can simply program to that generic API, and application code is not specific to any particular driver implementation.

A subsystem API definition typically looks like this:

```
typedef int (*subsystem_do_this_t)(const struct device *dev, int foo, int bar);
typedef void (*subsystem_do_that_t)(const struct device *dev, void *baz);

struct subsystem_api {
      subsystem_do_this_t do_this;
      subsystem_do_that_t do_that;
};

static inline int subsystem_do_this(const struct device *dev, int foo, int bar)
{
      struct subsystem_api *api;

      api = (struct subsystem_api *)dev->api;
      return api->do_this(dev, foo, bar);
}

static inline void subsystem_do_that(const struct device *dev, void *baz)
{
      struct subsystem_api *api;

      api = (struct subsystem_api *)dev->api;
      api->do_that(dev, baz);
}
```

A driver implementing a particular subsystem will define the real implementation of these APIs, and populate an instance of subsystem_api structure:

```
static int my_driver_do_this(const struct device *dev, int foo, int bar)
{
      ...
}

static void my_driver_do_that(const struct device *dev, void *baz)
{
      ...
```

(continues on next page)

(continued from previous page)

```
}

static struct subsystem_api my_driver_api_funcs = {
      .do_this = my_driver_do_this,
      .do_that = my_driver_do_that
};
```

The driver would then pass `my_driver_api_funcs` as the `api` argument to `DEVICE_DEFINE()`.

> **Note**
>
> Since pointers to the API functions are referenced in the `api` struct, they will always be included in the binary even if unused; `gc-sections` linker option will always see at least one reference to them. Providing for link-time size optimizations with driver APIs in most cases requires that the optional feature be controlled by a Kconfig option.

3.2.7 Device-Specific API Extensions

Some devices can be cast as an instance of a driver subsystem such as GPIO, but provide additional functionality that cannot be exposed through the standard API. These devices combine subsystem operations with device-specific APIs, described in a device-specific header.

A device-specific API definition typically looks like this:

```
#include <zephyr/drivers/subsystem.h>

/* When extensions need not be invoked from user mode threads */
int specific_do_that(const struct device *dev, int foo);

/* When extensions must be invokable from user mode threads */
__syscall int specific_from_user(const struct device *dev, int bar);

/* Only needed when extensions include syscalls */
#include <zephyr/syscalls/specific.h>
```

A driver implementing extensions to the subsystem will define the real implementation of both the subsystem API and the specific APIs:

```
static int generic_do_this(const struct device *dev, void *arg)
{
   ...
}

static struct generic_api api {
   ...
   .do_this = generic_do_this,
   ...
};

/* supervisor-only API is globally visible */
int specific_do_that(const struct device *dev, int foo)
{
   ...
}

/* syscall API passes through a translation */
int z_impl_specific_from_user(const struct device *dev, int bar)
{
```

(continues on next page)

(continued from previous page)

```
    ...
}

#ifdef CONFIG_USERSPACE

#include <zephyr/internal/syscall_handler.h>

int z_vrfy_specific_from_user(const struct device *dev, int bar)
{
    K_OOPS(K_SYSCALL_SPECIFIC_DRIVER(dev, K_OBJ_DRIVER_GENERIC, &api));
    return z_impl_specific_do_that(dev, bar)
}

#include <zephyr/syscalls/specific_from_user_mrsh.c>

#endif /* CONFIG_USERSPACE */
```

Applications use the device through both the subsystem and specific APIs.

> **Note**
>
> Public API for device-specific extensions should be prefixed with the compatible for the device to which it applies. For example, if adding special functions to support the Maxim DS3231 the identifier fragment `specific` in the examples above would be `maxim_ds3231`.

3.2.8 Single Driver, Multiple Instances

Some drivers may be instantiated multiple times in a given system. For example there can be multiple GPIO banks, or multiple UARTS. Each instance of the driver will have a different `config` struct and `data` struct.

Configuring interrupts for multiple drivers instances is a special case. If each instance needs to configure a different interrupt line, this can be accomplished through the use of per-instance configuration functions, since the parameters to `IRQ_CONNECT()` need to be resolvable at build time.

For example, let's say we need to configure two instances of `my_driver`, each with a different interrupt line. In `drivers/subsystem/subsystem_my_driver.h`:

```
typedef void (*my_driver_config_irq_t)(const struct device *dev);

struct my_driver_config {
      DEVICE_MMIO_ROM;
      my_driver_config_irq_t config_func;
};
```

In the implementation of the common init function:

```
void my_driver_isr(const struct device *dev)
{
      /* Handle interrupt */
      ...
}

int my_driver_init(const struct device *dev)
{
      const struct my_driver_config *config = dev->config;
```

(continues on next page)

(continued from previous page)

```
	DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);

	/* Do other initialization stuff */
	...

	config->config_func(dev);

	return 0;
}
```

Then when the particular instance is declared:

```
#if CONFIG_MY_DRIVER_0

DEVICE_DECLARE(my_driver_0);

static void my_driver_config_irq_0(const struct device *dev)
{
	IRQ_CONNECT(MY_DRIVER_0_IRQ, MY_DRIVER_0_PRI, my_driver_isr,
		    DEVICE_GET(my_driver_0), MY_DRIVER_0_FLAGS);
}

const static struct my_driver_config my_driver_config_0 = {
	DEVICE_MMIO_ROM_INIT(DT_DRV_INST(0)),
	.config_func = my_driver_config_irq_0
}

static struct my_data_0;

DEVICE_DEFINE(my_driver_0, MY_DRIVER_0_NAME, my_driver_init,
	      NULL, &my_data_0, &my_driver_config_0,
	      POST_KERNEL, MY_DRIVER_0_PRIORITY, &my_api_funcs);

#endif /* CONFIG_MY_DRIVER_0 */
```

Note the use of DEVICE_DECLARE() to avoid a circular dependency on providing the IRQ handler argument and the definition of the device itself.

3.2.9 Initialization Levels

Drivers may depend on other drivers being initialized first, or require the use of kernel services. *DEVICE_DEFINE()* and related APIs allow the user to specify at what time during the boot sequence the init function will be executed. Any driver will specify one of four initialization levels:

PRE_KERNEL_1
: Used for devices that have no dependencies, such as those that rely solely on hardware present in the processor/SOC. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. The interrupt subsystem will be configured however so it's OK to set up interrupts. Init functions at this level run on the interrupt stack.

PRE_KERNEL_2
: Used for devices that rely on the initialization of devices initialized as part of the PRE_KERNEL_1 level. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. Init functions at this level run on the interrupt stack.

POST_KERNEL
: Used for devices that require kernel services during configuration. Init functions at this

level run in context of the kernel main task.

Within each initialization level you may specify a priority level, relative to other devices in the same initialization level. The priority level is specified as an integer value in the range 0 to 99; lower values indicate earlier initialization. The priority level must be a decimal integer literal without leading zeroes or sign (e.g. 32), or an equivalent symbolic name (e.g. `\#define MY_INIT_PRIO 32`); symbolic expressions are *not* permitted (e.g. `CONFIG_KERNEL_INIT_PRIORITY_DEFAULT + 5`).

Drivers and other system utilities can determine whether startup is still in pre-kernel states by using the *k_is_pre_kernel()* function.

3.2.10 Deferred initialization

Initialization of devices can also be deferred to a later time. In this case, the device is not automatically initialized by Zephyr at boot time. Instead, the device is initialized when the application calls *device_init()*. To defer a device driver initialization, add the property `zephyr,deferred-init` to the associated device node in the DTS file. For example:

```
/ {
        a-driver@40000000 {
                reg = <0x40000000 0x1000>;
                zephyr,deferred-init;
        };
};
```

3.2.11 System Drivers

In some cases you may just need to run a function at boot. For such cases, the `SYS_INIT` can be used. This macro does not take any config or runtime data structures and there isn't a way to later get a device pointer by name. The same device policies for initialization level and priority apply.

3.2.12 Inspecting the initialization sequence

Device drivers declared with *DEVICE_DEFINE* (or any variations of it) and `SYS_INIT` are processed at boot time and the corresponding initialization functions are called sequentially according to their specified level and priority.

Sometimes it's useful to inspect the final sequence of initialization function call as produced by the linker. To do that, use the `initlevels` CMake target, for example `west build -t initlevels`.

3.2.13 Error handling

In general, it's best to use `__ASSERT()` macros instead of propagating return values unless the failure is expected to occur during the normal course of operation (such as a storage device full). Bad parameters, programming errors, consistency checks, pathological/unrecoverable failures, etc., should be handled by assertions.

When it is appropriate to return error conditions for the caller to check, 0 should be returned on success and a POSIX `errno.h` code returned on failure. See https://github.com/zephyrproject-rtos/zephyr/wiki/Naming-Conventions#return-codes for details about this.

3.2.14 Memory Mapping

On some systems, the linear address of peripheral memory-mapped I/O (MMIO) regions cannot be known at build time:

- The I/O ranges must be probed at runtime from the bus, such as with PCI express
- A memory management unit (MMU) is active, and the physical address of the MMIO range must be mapped into the page tables at some virtual memory location determined by the kernel.

These systems must maintain storage for the MMIO range within RAM and establish the mapping within the driver's init function. Other systems do not care about this and can use MMIO physical addresses directly from DTS and do not need any RAM-based storage for it.

For drivers that may need to deal with this situation, a set of APIs under the DEVICE_MMIO scope are defined, along with a mapping function `device_map()`.

Device Model Drivers with one MMIO region

The simplest case is for drivers which need to maintain one MMIO region. These drivers will need to use the `DEVICE_MMIO_ROM` and `DEVICE_MMIO_RAM` macros in the definitions for their `config_info` and `driver_data` structures, with initialization of the `config_info` from DTS using `DEVICE_MMIO_ROM_INIT`. A call to `DEVICE_MMIO_MAP()` is made within the init function:

```
struct my_driver_config {
   DEVICE_MMIO_ROM; /* Must be first */
   ...
}

struct my_driver_dev_data {
   DEVICE_MMIO_RAM; /* Must be first */
   ...
}

const static struct my_driver_config my_driver_config_0 = {
   DEVICE_MMIO_ROM_INIT(DT_DRV_INST(...)),
   ...
}

int my_driver_init(const struct device *dev)
{
   ...
   DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);
   ...
}

int my_driver_some_function(const struct device *dev)
{
   ...
   /* Write some data to the MMIO region */
   sys_write32(0xDEADBEEF, DEVICE_MMIO_GET(dev));
   ...
}
```

The particular expansion of these macros depends on configuration. On a device with no MMU or PCI-e, `DEVICE_MMIO_MAP` and `DEVICE_MMIO_RAM` expand to nothing.

Device Model Drivers with multiple MMIO regions

Some drivers may have multiple MMIO regions. In addition, some drivers may already be implementing a form of inheritance which requires some other data to be placed first in the config_info and driver_data structures.

This can be managed with the DEVICE_MMIO_NAMED variant macros. These require that DEV_CFG() and DEV_DATA() macros be defined to obtain a properly typed pointer to the driver's config_info or dev_data structs. For example:

```
struct my_driver_config {
   ...
     DEVICE_MMIO_NAMED_ROM(corge);
     DEVICE_MMIO_NAMED_ROM(grault);
   ...
}

struct my_driver_dev_data {
        ...
     DEVICE_MMIO_NAMED_RAM(corge);
     DEVICE_MMIO_NAMED_RAM(grault);
     ...
}

#define DEV_CFG(_dev) \
   ((const struct my_driver_config *)((_dev)->config))

#define DEV_DATA(_dev) \
   ((struct my_driver_dev_data *)((_dev)->data))

const static struct my_driver_config my_driver_config_0 = {
   ...
   DEVICE_MMIO_NAMED_ROM_INIT(corge, DT_DRV_INST(...)),
   DEVICE_MMIO_NAMED_ROM_INIT(grault, DT_DRV_INST(...)),
   ...
}

int my_driver_init(const struct device *dev)
{
   ...
   DEVICE_MMIO_NAMED_MAP(dev, corge, K_MEM_CACHE_NONE);
   DEVICE_MMIO_NAMED_MAP(dev, grault, K_MEM_CACHE_NONE);
   ...
}

int my_driver_some_function(const struct device *dev)
{
   ...
   /* Write some data to the MMIO regions */
   sys_write32(0xDEADBEEF, DEVICE_MMIO_GET(dev, grault));
   sys_write32(0xF0CCAC1A, DEVICE_MMIO_GET(dev, corge));
   ...
}
```

Device Model Drivers with multiple MMIO regions in the same DT node

Some drivers may have multiple MMIO regions defined into the same DT device node using the reg-names property to differentiate them, for example:

```
/dts-v1/;

/ {
        a-driver@40000000 {
                reg = <0x40000000 0x1000>,
                      <0x40001000 0x1000>;
                reg-names = "corge", "grault";
        };
};
```

This can be managed as seen in the previous section but this time using the DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME macro instead. So the only difference would be in the driver config struct:

```
const static struct my_driver_config my_driver_config_0 = {
   ...
   DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME(corge, DT_DRV_INST(...)),
   DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME(grault, DT_DRV_INST(...)),
   ...
}
```

Drivers that do not use Zephyr Device Model

Some drivers or driver-like code may not user Zephyr's device model, and alternative storage must be arranged for the MMIO data. An example of this are timer drivers, or interrupt controller code.

This can be managed with the DEVICE_MMIO_TOPLEVEL set of macros, for example:

```
DEVICE_MMIO_TOPLEVEL_STATIC(my_regs, DT_DRV_INST(..));

void some_init_code(...)
{
   ...
   DEVICE_MMIO_TOPLEVEL_MAP(my_regs, K_MEM_CACHE_NONE);
   ...
}

void some_function(...)
   ...
   sys_write32(DEVICE_MMIO_TOPLEVEL_GET(my_regs), 0xDEADBEEF);
   ...
}
```

Drivers that do not use DTS

Some drivers may not obtain the MMIO physical address from DTS, such as is the case with PCI-E. In this case the device_map() function may be used directly:

```
void some_init_code(...)
{
   ...
   struct pcie_bar mbar;
   bool bar_found = pcie_get_mbar(bdf, index, &mbar);

   device_map(DEVICE_MMIO_RAM_PTR(dev), mbar.phys_addr, mbar.size, K_MEM_CACHE_NONE);
   ...
}
```

For these cases, DEVICE_MMIO_ROM directives may be omitted.

3.2.15 API Reference

group `device_model`

Device Model.

Since
1.0

Version
1.1.0

Defines

`DEVICE_HANDLE_NULL`

Flag value used to identify an unknown device.

`DEVICE_NAME_GET`(dev_id)

Expands to the name of a global device object.

Return the full name of a device object symbol created by *DEVICE_DEFINE()*, using the `dev_id` provided to *DEVICE_DEFINE()*. This is the name of the global variable storing the device structure, not a pointer to the string in the *device::name* field.

It is meant to be used for declaring extern symbols pointing to device objects before using the DEVICE_GET macro to get the device object.

This macro is normally only useful within device driver source code. In other situations, you are probably looking for *device_get_binding()*.

Parameters

- `dev_id` – Device identifier.

Returns
The full name of the device object defined by device definition macros.

`DEVICE_DEFINE`(dev_id, name, init_fn, pm, data, config, level, prio, api)

Create a device object and set it up for boot time initialization.

This macro defines a *device* that is automatically configured by the kernel during system initialization. This macro should only be used when the device is not being allocated from a devicetree node. If you are allocating a device from a devicetree node, use *DEVICE_DT_DEFINE()* or *DEVICE_DT_INST_DEFINE()* instead.

Parameters

- `dev_id` – A unique token which is used in the name of the global device structure as a C identifier.
- `name` – A string name for the device, which will be stored in *device::name*. This name can be used to look up the device with *device_get_binding()*. This must be less than Z_DEVICE_MAX_NAME_LEN characters (including terminating `NULL`) in order to be looked up from user mode.
- `init_fn` – Pointer to the device's initialization function, which will be run by the kernel during system initialization. Can be `NULL`.

- **pm** – Pointer to the device's power management resources, a *pm_device*, which will be stored in device::pm field. Use NULL if the device does not use PM.
- **data** – Pointer to the device's private mutable data, which will be stored in *device::data*.
- **config** – Pointer to the device's private constant data, which will be stored in *device::config*.
- **level** – The device's initialization level (PRE_KERNEL_1, PRE_KERNEL_2 or POST_KERNEL).
- **prio** – The device's priority within its initialization level. See SYS_INIT() for details.
- **api** – Pointer to the device's API structure. Can be NULL.

DEVICE_DT_NAME(node_id)

Return a string name for a devicetree node.

This macro returns a string literal usable as a device's name from a devicetree node identifier.

Parameters

- **node_id** – The devicetree node identifier.

Returns

The value of the node's label property, if it has one. Otherwise, the node's full name in node-name@unit-address form.

DEVICE_DT_DEFER(node_id)

Determine if a devicetree node initialization should be deferred.

Parameters

- **node_id** – The devicetree node identifier.

Returns

Boolean stating if node initialization should be deferred.

DEVICE_DT_DEFINE(node_id, init_fn, pm, data, config, level, prio, api, ...)

Create a device object from a devicetree node identifier and set it up for boot time initialization.

This macro defines a *device* that is automatically configured by the kernel during system initialization. The global device object's name as a C identifier is derived from the node's dependency ordinal. *device::name* is set to *DEVICE_DT_NAME(node_id)*.

The device is declared with extern visibility, so a pointer to a global device object can be obtained with *DEVICE_DT_GET(node_id)* from any source file that includes <zephyr/device.h>. Before using the pointer, the referenced object should be checked using *device_is_ready()*.

Parameters

- **node_id** – The devicetree node identifier.
- **init_fn** – Pointer to the device's initialization function, which will be run by the kernel during system initialization. Can be NULL.
- **pm** – Pointer to the device's power management resources, a *pm_device*, which will be stored in device::pm. Use NULL if the device does not use PM.
- **data** – Pointer to the device's private mutable data, which will be stored in *device::data*.

- **config** – Pointer to the device's private constant data, which will be stored in *device::config* field.
- **level** – The device's initialization level (PRE_KERNEL_1, PRE_KERNEL_2 or POST_KERNEL).
- **prio** – The device's priority within its initialization level. See SYS_INIT() for details.
- **api** – Pointer to the device's API structure. Can be `NULL`.

`DEVICE_DT_INST_DEFINE`(inst, ...)

Like *DEVICE_DT_DEFINE()*, but uses an instance of a `DT_DRV_COMPAT` compatible instead of a node identifier.

Parameters

- **inst** – Instance number. The `node_id` argument to *DEVICE_DT_DEFINE()* is set to *DT_DRV_INST(inst)*.
- **...** – Other parameters as expected by *DEVICE_DT_DEFINE()*.

`DEVICE_DT_NAME_GET`(node_id)

The name of the global device object for `node_id`.

Returns the name of the global device structure as a C identifier. The device must be allocated using *DEVICE_DT_DEFINE()* or *DEVICE_DT_INST_DEFINE()* for this to work.

This macro is normally only useful within device driver source code. In other situations, you are probably looking for *DEVICE_DT_GET()*.

Parameters

- **node_id** – Devicetree node identifier

Returns
The name of the device object as a C identifier

`DEVICE_DT_GET`(node_id)

Get a *device* reference from a devicetree node identifier.

Returns a pointer to a device object created from a devicetree node, if any device was allocated by a driver.

If no such device was allocated, this will fail at linker time. If you get an error that looks like `undefined reference to __device_dts_ord_<N>`, that is what happened. Check to make sure your device driver is being compiled, usually by enabling the Kconfig options it requires.

Parameters

- **node_id** – A devicetree node identifier

Returns
A pointer to the device object created for that node

`DEVICE_DT_INST_GET`(inst)

Get a *device* reference for an instance of a `DT_DRV_COMPAT` compatible.

This is equivalent to *DEVICE_DT_GET(DT_DRV_INST(inst))*.

Parameters

- **inst** – `DT_DRV_COMPAT` instance number

Returns
A pointer to the device object created for that instance

DEVICE_DT_GET_ANY(compat)

Get a *device* reference from a devicetree compatible.

If an enabled devicetree node has the given compatible and a device object was created from it, this returns a pointer to that device.

If there no such devices, this returns NULL.

If there are multiple, this returns an arbitrary one.

If this returns non-NULL, the device must be checked for readiness before use, e.g. with *device_is_ready()*.

Parameters

- **compat** – lowercase-and-underscores devicetree compatible

Returns
a pointer to a device, or NULL

DEVICE_DT_GET_ONE(compat)

Get a *device* reference from a devicetree compatible.

If an enabled devicetree node has the given compatible and a device object was created from it, this returns a pointer to that device.

If there are no such devices, this will fail at compile time.

If there are multiple, this returns an arbitrary one.

If this returns non-NULL, the device must be checked for readiness before use, e.g. with *device_is_ready()*.

Parameters

- **compat** – lowercase-and-underscores devicetree compatible

Returns
a pointer to a device

DEVICE_DT_GET_OR_NULL(node_id)

Utility macro to obtain an optional reference to a device.

If the node identifier refers to a node with status `okay`, this returns *DEVICE_DT_GET(node_id)*. Otherwise, it returns `NULL`.

Parameters

- **node_id** – devicetree node identifier

Returns
a *device* reference for the node identifier, which may be `NULL`.

DEVICE_GET(dev_id)

Obtain a pointer to a device object by name.

Return the address of a device object created by *DEVICE_DEFINE()*, using the dev_id provided to *DEVICE_DEFINE()*.

Parameters

- **dev_id** – Device identifier.

Returns
A pointer to the device object created by *DEVICE_DEFINE()*

DEVICE_DECLARE(dev_id)

Declare a static device object.

This macro can be used at the top-level to declare a device, such that *DEVICE_GET()* may be used before the full declaration in *DEVICE_DEFINE()*.

This is often useful when configuring interrupts statically in a device's init or per-instance config function, as the init function itself is required by *DEVICE_DEFINE()* and use of *DEVICE_GET()* inside it creates a circular dependency.

Parameters

- dev_id – Device identifier.

DEVICE_INIT_DT_GET(node_id)

Get a init_entry reference from a devicetree node.

Parameters

- node_id – A devicetree node identifier

Returns

A pointer to the init_entry object created for that node

DEVICE_INIT_GET(dev_id)

Get a init_entry reference from a device identifier.

Parameters

- dev_id – Device identifier.

Returns

A pointer to the init_entry object created for that device

Typedefs

typedef int16_t device_handle_t

Type used to represent a "handle" for a device.

Every *device* has an associated handle. You can get a pointer to a *device* from its handle and vice versa, but the handle uses less space than a pointer. The device.h API mainly uses handles to store lists of multiple devices in a compact way.

The extreme values and zero have special significance. Negative values identify functionality that does not correspond to a Zephyr device, such as the system clock or a SYS_INIT() function.

See also

device_handle_get()

See also

device_from_handle()

typedef int (*`device_visitor_callback_t`)(const struct *device* *dev, void *context)

Prototype for functions used when iterating over a set of devices.

Such a function may be used in API that identifies a set of devices and provides a visitor API supporting caller-specific interaction with each device in the set.

The visit is said to succeed if the visitor returns a non-negative value.

See also

device_required_foreach()

See also

device_supported_foreach()

Param dev
a device in the set being iterated

Param context
state used to support the visitor function

Return
A non-negative number to allow walking to continue, and a negative error code to case the iteration to stop.

Functions

static inline *device_handle_t* `device_handle_get`(const struct *device* *dev)

Get the handle for a given device.

Parameters

- `dev` – the device for which a handle is desired.

Returns
the handle for the device, or DEVICE_HANDLE_NULL if the device does not have an associated handle.

static inline const struct *device* *`device_from_handle`(*device_handle_t* dev_handle)

Get the device corresponding to a handle.

Parameters

- `dev_handle` – the device handle

Returns
the device that has that handle, or a null pointer if `dev_handle` does not identify a device.

static inline const *device_handle_t* *`device_required_handles_get`(const struct *device* *dev, size_t *count)

Get the device handles for devicetree dependencies of this device.

This function returns a pointer to an array of device handles. The length of the array is stored in the `count` parameter.

The array contains a handle for each device that dev requires directly, as determined from the devicetree. This does not include transitive dependencies; you must recursively determine those.

Parameters

- **dev** – the device for which dependencies are desired.
- **count** – pointer to where this function should store the length of the returned array. No value is stored if the call returns a null pointer. The value may be set to zero if the device has no devicetree dependencies.

Returns

a pointer to a sequence of count device handles, or a null pointer if dev does not have any dependency data.

static inline const *device_handle_t* ***device_injected_handles_get**(const struct *device* *dev, size_t *count)

Get the device handles for injected dependencies of this device.

This function returns a pointer to an array of device handles. The length of the array is stored in the count parameter.

The array contains a handle for each device that dev manually injected as a dependency, via providing extra arguments to Z_DEVICE_DEFINE. This does not include transitive dependencies; you must recursively determine those.

Parameters

- **dev** – the device for which injected dependencies are desired.
- **count** – pointer to where this function should store the length of the returned array. No value is stored if the call returns a null pointer. The value may be set to zero if the device has no devicetree dependencies.

Returns

a pointer to a sequence of *count device handles, or a null pointer if dev does not have any dependency data.

static inline const *device_handle_t* ***device_supported_handles_get**(const struct *device* *dev, size_t *count)

Get the set of handles that this device supports.

This function returns a pointer to an array of device handles. The length of the array is stored in the count parameter.

The array contains a handle for each device that dev “supports” — that is, devices that require dev directly — as determined from the devicetree. This does not include transitive dependencies; you must recursively determine those.

Parameters

- **dev** – the device for which supports are desired.
- **count** – pointer to where this function should store the length of the returned array. No value is stored if the call returns a null pointer. The value may be set to zero if nothing in the devicetree depends on dev.

Returns

a pointer to a sequence of *count device handles, or a null pointer if dev does not have any dependency data.

int **device_required_foreach**(const struct *device* *dev, *device_visitor_callback_t* visitor_cb, void *context)

Visit every device that dev directly requires.

Zephyr maintains information about which devices are directly required by another device; for example an I2C-based sensor driver will require an I2C controller for communication. Required devices can derive from statically-defined devicetree relationships or dependencies registered at runtime.

This API supports operating on the set of required devices. Example uses include making sure required devices are ready before the requiring device is used, and releasing them when the requiring device is no longer needed.

There is no guarantee on the order in which required devices are visited.

If the `visitor_cb` function returns a negative value iteration is halted, and the returned value from the visitor is returned from this function.

> **Note**
>
> This API is not available to unprivileged threads.

Parameters

- **`dev`** – a device of interest. The devices that this device depends on will be used as the set of devices to visit. This parameter must not be null.
- **`visitor_cb`** – the function that should be invoked on each device in the dependency set. This parameter must not be null.
- **`context`** – state that is passed through to the visitor function. This parameter may be null if `visitor_cb` tolerates a null `context`.

Returns

The number of devices that were visited if all visits succeed, or the negative value returned from the first visit that did not succeed.

int **`device_supported_foreach`**(const struct *device* *dev, *device_visitor_callback_t* visitor_cb, void *context)

Visit every device that `dev` directly supports.

Zephyr maintains information about which devices are directly supported by another device; for example an I2C controller will support an I2C-based sensor driver. Supported devices can derive from statically-defined devicetree relationships.

This API supports operating on the set of supported devices. Example uses include iterating over the devices connected to a regulator when it is powered on.

There is no guarantee on the order in which required devices are visited.

If the `visitor_cb` function returns a negative value iteration is halted, and the returned value from the visitor is returned from this function.

> **Note**
>
> This API is not available to unprivileged threads.

Parameters

- **`dev`** – a device of interest. The devices that this device supports will be used as the set of devices to visit. This parameter must not be null.
- **`visitor_cb`** – the function that should be invoked on each device in the support set. This parameter must not be null.

- **context** – state that is passed through to the visitor function. This parameter may be null if `visitor_cb` tolerates a null `context`.

Returns
The number of devices that were visited if all visits succeed, or the negative value returned from the first visit that did not succeed.

const struct *device* ***device_get_binding**(const char *name)

Get a *device* reference from its *device::name* field.

This function iterates through the devices on the system. If a device with the given `name` field is found, and that device initialized successfully at boot time, this function returns a pointer to the device.

If no device has the given `name`, this function returns `NULL`.

This function also returns NULL when a device is found, but it failed to initialize successfully at boot time. (To troubleshoot this case, set a breakpoint on your device driver's initialization function.)

Parameters

- **name** – device name to search for. A null pointer, or a pointer to an empty string, will cause NULL to be returned.

Returns
pointer to device structure with the given name; `NULL` if the device is not found or if the device with that name's initialization function failed.

bool **device_is_ready**(const struct *device* *dev)

Verify that a device is ready for use.

Indicates whether the provided device pointer is for a device known to be in a state where it can be used with its standard API.

This can be used with device pointers captured from *DEVICE_DT_GET()*, which does not include the readiness checks of *device_get_binding()*. At minimum this means that the device has been successfully initialized.

Parameters

- **dev** – pointer to the device in question.

Return values

- **true** – If the device is ready for use.
- **false** – If the device is not ready for use or if a NULL device pointer is passed as argument.

int **device_init**(const struct *device* *dev)

Initialize a device.

A device whose initialization was deferred (by marking it as `zephyr,deferred-init` on devicetree) needs to be initialized manually via this call. Note that only devices whose initialization was deferred can be initialized via this call - one can not try to initialize a non initialization deferred device that failed initialization with this call.

Parameters

- **dev** – device to be initialized.

Return values

- **-ENOENT** – If device was not found - or isn't a deferred one.
- **-errno** – For other errors.

struct **device_state**

#include <device.h> Runtime device dynamic structure (in RAM) per driver instance.

Fields in this are expected to be default-initialized to zero. The kernel driver infrastructure and driver access functions are responsible for ensuring that any non-zero initialization is done before they are accessed.

Public Members

uint8_t **init_res**

Device initialization return code (positive errno value).

Device initialization functions return a negative errno code if they fail. In Zephyr, errno values do not exceed 255, so we can store the positive result value in a uint8_t type.

bool **initialized**

Indicates the device initialization function has been invoked.

struct **device**

#include <device.h> Runtime device structure (in ROM) per driver instance.

Public Members

const char ***name**

Name of the device instance.

const void ***config**

Address of device instance config information.

const void ***api**

Address of the API structure exposed by the device instance.

struct *device_state* ***state**

Address of the common device state.

void ***data**

Address of the device instance private data.

const *device_handle_t* ***deps**

Optional pointer to dependencies associated with the device.

This encodes a sequence of sets of device handles that have some relationship to this node. The individual sets are extracted with dedicated API, such as *device_required_handles_get()*. Only available if `CONFIG_DEVICE_DEPS` is enabled.

union device

Reference to the device PM resources (only available if `CONFIG_PM_DEVICE` is enabled).

3.3 User Mode

Zephyr offers the capability to run threads at a reduced privilege level which we call user mode. The current implementation is designed for devices with MPU hardware.

For details on creating threads that run in user mode, please see *Lifecycle*.

3.3.1 Overview

Threat Model

User mode threads are considered to be untrusted by Zephyr and are therefore isolated from other user mode threads and from the kernel. A flawed or malicious user mode thread cannot leak or modify the private data/resources of another thread or the kernel, and cannot interfere with or control another user mode thread or the kernel.

Example use-cases of Zephyr's user mode features:

- The kernel can protect against many unintentional programming errors which could otherwise silently or spectacularly corrupt the system.
- The kernel can sandbox complex data parsers such as interpreters, network protocols, and filesystems such that malicious third-party code or data cannot compromise the kernel or other threads.
- The kernel can support the notion of multiple logical "applications", each with their own group of threads and private data structures, which are isolated from each other if one crashes or is otherwise compromised.

Design Goals For threads running in a non-privileged CPU state (hereafter referred to as 'user mode') we aim to protect against the following:

- We prevent access to memory not specifically granted, or incorrect access to memory that has an incompatible policy, such as attempting to write to a read-only area.
  - Access to thread stack buffers will be controlled with a policy which partially depends on the underlying memory protection hardware.
    - A user thread will by default have read/write access to its own stack buffer.
    - A user thread will never by default have access to user thread stacks that are not members of the same memory domain.
    - A user thread will never by default have access to thread stacks owned by a supervisor thread, or thread stacks used to handle system call privilege elevations, interrupts, or CPU exceptions.
    - A user thread may have read/write access to the stacks of other user threads in the same memory domain, depending on hardware.
      - On MPU systems, threads may only access their own stack buffer.
      - On MMU systems, threads may access any user thread stack in the same memory domain. Portable code should not assume this.
  - By default, program text and read-only data are accessible to all threads on read-only basis, kernel-wide. This policy may be adjusted.
  - User threads by default are not granted default access to any memory except what is noted above.
- We prevent use of device drivers or kernel objects not specifically granted, with the permission granularity on a per object or per driver instance basis.

- We validate kernel or driver API calls with incorrect parameters that would otherwise cause a crash or corruption of data structures private to the kernel. This includes:
  - Using the wrong kernel object type.
  - Using parameters outside of proper bounds or with nonsensical values.
  - Passing memory buffers that the calling thread does not have sufficient access to read or write, depending on the semantics of the API.
  - Use of kernel objects that are not in a proper initialization state.
- We ensure the detection and safe handling of user mode stack overflows.
- We prevent invoking system calls to functions excluded by the kernel configuration.
- We prevent disabling of or tampering with kernel-defined and hardware- enforced memory protections.
- We prevent re-entry from user to supervisor mode except through the kernel- defined system calls and interrupt handlers.
- We prevent the introduction of new executable code by user mode threads, except to the extent to which this is supported by kernel system calls.

We are specifically not protecting against the following attacks:

- The kernel itself, and any threads that are executing in supervisor mode, are assumed to be trusted.
- The toolchain and any supplemental programs used by the build system are assumed to be trusted.
- The kernel build is assumed to be trusted. There is considerable build-time logic for creating the tables of valid kernel objects, defining system calls, and configuring interrupts. The .elf binary files that are worked with during this process are all assumed to be trusted code.
- We can't protect against mistakes made in memory domain configuration done in kernel mode that exposes private kernel data structures to a user thread. RAM for kernel objects should always be configured as supervisor-only.
- It is possible to make top-level declarations of user mode threads and assign them permissions to kernel objects. In general, all C and header files that are part of the kernel build producing zephyr.elf are assumed to be trusted.
- We do not protect against denial of service attacks through thread CPU starvation. Zephyr has no thread priority aging and a user thread of a particular priority can starve all threads of lower priority, and also other threads of the same priority if time-slicing is not enabled.
- There are build-time defined limits on how many threads can be active simultaneously, after which creation of new user threads will fail.
- Stack overflows for threads running in supervisor mode may be caught, but the integrity of the system cannot be guaranteed.

High-level Policy Details

Broadly speaking, we accomplish these thread-level memory protection goals through the following mechanisms:

- Any user thread will only have access to a subset of memory: typically its stack, program text, read-only data, and any partitions configured in the *Memory Protection Design* it belongs to. Access to any other RAM must be done on the thread's behalf through system calls, or specifically granted by a supervisor thread using the memory domain APIs. Newly created threads inherit the memory domain configuration of the parent. Threads may communicate with each other by having shared membership of the same memory domains, or via kernel objects such as semaphores and pipes.

- User threads cannot directly access memory belonging to kernel objects. Although pointers to kernel objects are used to reference them, actual manipulation of kernel objects is done through system call interfaces. Device drivers and threads stacks are also considered kernel objects. This ensures that any data inside a kernel object that is private to the kernel cannot be tampered with.
- User threads by default have no permission to access any kernel object or driver other than their own thread object. Such access must be granted by another thread that is either in supervisor mode or has permission on both the receiving thread object and the kernel object being granted access to. The creation of new threads has an option to automatically inherit permissions of all kernel objects granted to the parent, except the parent thread itself.
- For performance and footprint reasons Zephyr normally does little or no parameter error checking for kernel object or device driver APIs. Access from user mode through system calls involves an extra layer of handler functions, which are expected to rigorously validate access permissions and type of the object, check the validity of other parameters through bounds checking or other means, and verify proper read/write access to any memory buffers involved.
- Thread stacks are defined in such a way that exceeding the specified stack space will generate a hardware fault. The way this is done specifically varies per architecture.

Constraints

All kernel objects, thread stacks, and device driver instances must be defined at build time if they are to be used from user mode. Dynamic use-cases for kernel objects will need to go through predefined pools of available objects.

There are some constraints if additional application binary data is loaded for execution after the kernel starts:

- Loaded object code will not be able to define any kernel objects that will be recognized by the kernel. This code will instead need to use APIs for requesting kernel objects from pools.
- Similarly, since the loaded object code will not be part of the kernel build process, this code will not be able to install interrupt handlers, instantiate device drivers, or define system calls, regardless of what mode it runs in.
- Loaded object code that does not come from a verified source should always be entered with the CPU already in user mode.

3.3.2 Memory Protection Design

Zephyr's memory protection design is geared towards microcontrollers with MPU (Memory Protection Unit) hardware. We do support some architectures, such as x86, which have a paged MMU (Memory Management Unit), but in that case the MMU is used like an MPU with an identity page table.

All of the discussion below will be using MPU terminology; systems with MMUs can be considered to have an MPU with an unlimited number of programmable regions.

There are a few different levels on how memory access is configured when Zephyr memory protection features are enabled, which we will describe here:

Boot Time Memory Configuration

This is the configuration of the MPU after the kernel has started up. It should contain the following:

- Any configuration of memory regions which need to have special caching or write-back policies for basic hardware and driver function. Note that most MPUs have the concept of a default memory access policy map, which can be enabled as a "background" mapping for any area of memory that doesn't have an MPU region configuring it. It is strongly recommended to use this to maximize the number of available MPU regions for the end user. On ARMv7-M/ARMv8-M this is called the System Address Map, other CPUs may have similar capabilities.
- A read-only, executable region or regions for program text and ro-data, that is accessible to user mode. This could be further sub-divided into a read-only region for ro-data, and a read-only, executable region for text, but this will require an additional MPU region. This is required so that threads running in user mode can read ro-data and fetch instructions.
- Depending on configuration, user-accessible read-write regions to support extra features like GCOV, HEP, etc.

Assuming there is a background map which allows supervisor mode to access any memory it needs, and regions are defined which grant user mode access to text/ro-data, this is sufficient for the boot time configuration.

Hardware Stack Overflow

`CONFIG_HW_STACK_PROTECTION` is an optional feature which detects stack buffer overflows when the system is running in supervisor mode. This catches issues when the entire stack buffer has overflowed, and not individual stack frames, use compiler-assisted `CONFIG_STACK_CANARIES` for that.

Like any crash in supervisor mode, no guarantees can be made about the overall health of the system after a supervisor mode stack overflow, and any instances of this should be treated as a serious error. However it's still very useful to know when these overflows happen, as without robust detection logic the system will either crash in mysterious ways or behave in an undefined manner when the stack buffer overflows.

Some systems implement this feature by creating at runtime a 'guard' MPU region which is set to be read-only and is at either the beginning or immediately preceding the supervisor mode stack buffer. If the stack overflows an exception will be generated.

This feature is optional and is not required to catch stack overflows in user mode; disabling this may free 1-2 MPU regions depending on the MPU design.

Other systems may have dedicated CPU support for catching stack overflows and no extra MPU regions will be required.

Thread Stack

Any thread running in user mode will need access to its own stack buffer. On context switch into a user mode thread, a dedicated MPU region or MMU page table entries will be programmed with the bounds of the stack buffer. A thread exceeding its stack buffer will start pushing data onto memory it doesn't have access to and a memory access violation exception will be generated.

Note that user threads have access to the stacks of other user threads in the same memory domain. This is the minimum required for architectures to support memory domains. Architecture can further restrict access to stacks so each user thread only has access to its own stack if such architecture advertises this capability via `CONFIG_ARCH_MEM_DOMAIN_SUPPORTS_ISOLATED_STACKS`. This behavior is enabled by default if supported and can be selectively disabled via `CONFIG_MEM_DOMAIN_ISOLATED_STACKS` if architecture supports both operating modes. However, some architectures may decide to enable this all the time, and thus this option cannot be disabled. Regardless of these kconfigs, user threads cannot access the stacks of other user threads outside of their memory domains.

Thread Resource Pools

A small subset of kernel APIs, invoked as system calls, require heap memory allocations. This memory is used only by the kernel and is not accessible directly by user mode. In order to use these system calls, invoking threads must assign themselves to a resource pool, which is a *k_heap* object. Memory is drawn from a thread's resource pool using `z_thread_malloc()` and freed with *k_free()*.

The APIs which use resource pools are as follows, with any alternatives noted for users who do not want heap allocations within their application:

- *k_stack_alloc_init()* sets up a k_stack with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare k_stacks that are automatically initialized at boot with *K_STACK_DEFINE()*, or to initialize the k_stack in supervisor mode with *k_stack_init()*.
- *k_pipe_alloc_init()* sets up a k_pipe object with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare k_pipes that are automatically initialized at boot with *K_PIPE_DEFINE()*, or to initialize the k_pipe in supervisor mode with *k_pipe_init()*.
- *k_msgq_alloc_init()* sets up a k_msgq object with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare a k_msgq that is automatically initialized at boot with *K_MSGQ_DEFINE()*, or to initialize the k_msgq in supervisor mode with *k_msgq_init()*.
- *k_poll()* when invoked from user mode, needs to make a kernel-side copy of the provided events array while waiting for an event. This copy is freed when *k_poll()* returns for any reason.
- *k_queue_alloc_prepend()* and *k_queue_alloc_append()* allocate a container structure to place the data in, since the internal bookkeeping information that defines the queue cannot be placed in the memory provided by the user.
- *k_object_alloc()* allows for entire kernel objects to be dynamically allocated at runtime and a usable pointer to them returned to the caller.

The relevant API is *k_thread_heap_assign()* which assigns a k_heap to draw these allocations from for the target thread.

If the system heap is enabled, then the system heap may be used with `k_thread_system_pool_assign()`, but it is preferable for different logical applications running on the system to have their own pools.

Memory Domains

The kernel ensures that any user thread will have access to its own stack buffer, plus program text and read-only data. The memory domain APIs are the way to grant access to additional blocks of memory to a user thread.

Conceptually, a memory domain is a collection of some number of memory partitions. The maximum number of memory partitions in a domain is limited by the number of available MPU regions. This is why it is important to minimize the number of boot-time MPU regions.

Memory domains are *not* intended to control access to memory from supervisor mode. In some cases this may be unavoidable; for example some architectures do not allow for the definition of regions which are read-only to user mode but read-write to supervisor mode. A great deal of care must be taken when working with such regions to not unintentionally cause the kernel to crash when accessing such a region. Any attempt to use memory domain APIs to control supervisor mode access is at best undefined behavior; supervisor mode access policy is only intended to be controlled by boot-time memory regions.

Memory domain APIs are only available to supervisor mode. The only control user mode has over memory domains is that any user thread's child threads will automatically become members of the parent's domain.

All threads are members of a memory domain, including supervisor threads (even though this has no implications on their memory access). There is a default domain `k_mem_domain_default` which will be assigned to threads if they have not been specifically assigned to a domain, or inherited a memory domain membership from their parent thread. The main thread starts as a member of the default domain.

Memory Partitions Each memory partition consists of a memory address, a size, and access attributes. It is intended that memory partitions are used to control access to system memory. Defining memory partitions are subject to the following constraints:

- The partition must represent a memory region that can be programmed by the underlying memory management hardware, and needs to conform to any underlying hardware constraints. For example, many MPU-based systems require that partitions be sized to some power of two, and aligned to their own size. For MMU-based systems, the partition must be aligned to a page and the size some multiple of the page size.
- Partitions within the same memory domain may not overlap each other. There is no notion of precedence among partitions within a memory domain. Partitions within a memory domain are assumed to have a higher precedence than any boot-time memory regions, however whether a memory domain partition can overlap a boot-time memory region is architecture specific.
- The same partition may be specified in multiple memory domains. For example there may be a shared memory area that multiple domains grant access to.
- Care must be taken in determining what memory to expose in a partition. It is not appropriate to provide direct user mode access to any memory containing private kernel data.
- Memory domain partitions are intended to control access to system RAM. Configuration of memory partitions which do not correspond to RAM may not be supported by the architecture; this is true for MMU-based systems.

There are two ways to define memory partitions: either manually or automatically.

Manual Memory Partitions The following code declares a global array `buf`, and then declares a read-write partition for it which may be added to a domain:

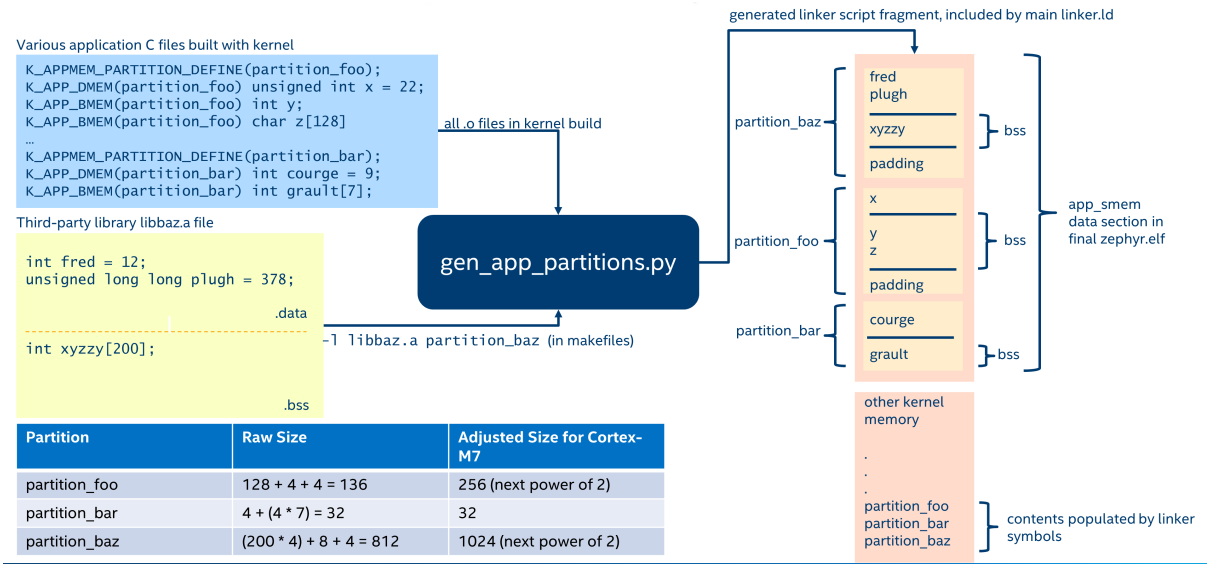
```
uint8_t __aligned(32) buf[32];

K_MEM_PARTITION_DEFINE(my_partition, buf, sizeof(buf),
                       K_MEM_PARTITION_P_RW_U_RW);
```

This does not scale particularly well when we are trying to contain multiple objects spread out across several C files into a single partition.

Automatic Memory Partitions Automatic memory partitions are created by the build system. All globals which need to be placed inside a partition are tagged with their destination partition. The build system will then coalesce all of these into a single contiguous block of memory, zero any BSS variables at boot, and define a memory partition of appropriate base address and size which contains all the tagged data.

Automatic memory partitions are only configured as read-write regions. They are defined with `K_APPMEM_PARTITION_DEFINE()`. Global variables are then routed to this partition using `K_APP_DMEM()` for initialized data and `K_APP_BMEM()` for BSS.



Partition	Raw Size	Adjusted Size for Cortex-M7
partition_foo	128 + 4 + 4 = 136	256 (next power of 2)
partition_bar	4 + (4 * 7) = 32	32
partition_baz	(200 * 4) + 8 + 4 = 812	1024 (next power of 2)

Fig. 2: Automatic Memory Domain build flow

```
#include <zephyr/app_memory/app_memdomain.h>

/* Declare a k_mem_partition "my_partition" that is read-write to
 * user mode. Note that we do not specify a base address or size.
 */
K_APPMEM_PARTITION_DEFINE(my_partition);

/* The global variable var1 will be inside the bounds of my_partition
 * and be initialized with 37 at boot.
 */
K_APP_DMEM(my_partition) int var1 = 37;

/* The global variable var2 will be inside the bounds of my_partition
 * and be zeroed at boot size K_APP_BMEM() was used, indicating a BSS
 * variable.
 */
K_APP_BMEM(my_partition) int var2;
```

The build system will ensure that the base address of `my_partition` will be properly aligned, and the total size of the region conforms to the memory management hardware requirements, adding padding if necessary.

If multiple partitions are being created, a variadic preprocessor macro can be used as provided in `app_macro_support.h`:

```
FOR_EACH(K_APPMEM_PARTITION_DEFINE, part0, part1, part2);
```

Automatic Partitions for Static Library Globals The build-time logic for setting up automatic memory partitions is in `scripts/build/gen_app_partitions.py`. If a static library is linked into Zephyr, it is possible to route all the globals in that library to a specific memory partition with the `--library` argument.

For example, if the Newlib C library is enabled, the Newlib globals all need to be placed in `z_libc_partition`. The invocation of the script in the top-level `CMakeLists.txt` adds the following:

```
gen_app_partitions.py ... --library libc.a z_libc_partition ..
```

For pre-compiled libraries there is no support for expressing this in the project-level configuration or build files; the toplevel `CMakeLists.txt` must be edited.

For Zephyr libraries created using `zephyr_library` or `zephyr_library_named` the `zephyr_library_app_memory` function can be used to specify the memory partition where all globals in the library should be placed.

Pre-defined Memory Partitions There are a few memory partitions which are pre-defined by the system:

- `z_malloc_partition` - This partition contains the system-wide pool of memory used by libc malloc(). Due to possible starvation issues, it is not recommended to draw heap memory from a global pool, instead it is better to define various sys_heap objects and assign them to specific memory domains.
- `z_libc_partition` - Contains globals required by the C library and runtime. Required when using either the Minimal C library or the Newlib C Library. Required when `CONFIG_STACK_CANARIES` is enabled.

Library-specific partitions are listed in `include/app_memory/partitions.h`. For example, to use the MBEDTLS library from user mode, the `k_mbedtls_partition` must be added to the domain.

Memory Domain Usage

Create a Memory Domain A memory domain is defined using a variable of type *k_mem_domain*. It must then be initialized by calling *k_mem_domain_init()*.

The following code defines and initializes an empty memory domain.

```
struct k_mem_domain app0_domain;

k_mem_domain_init(&app0_domain, 0, NULL);
```

Add Memory Partitions into a Memory Domain There are two ways to add memory partitions into a memory domain.

This first code sample shows how to add memory partitions while creating a memory domain.

```
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];

K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
                       K_MEM_PARTITION_P_RW_U_RW);

K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
                       K_MEM_PARTITION_P_RW_U_RO);

struct k_mem_partition *app0_parts[] = {
    app0_part0,
    app0_part1
};

k_mem_domain_init(&app0_domain, ARRAY_SIZE(app0_parts), app0_parts);
```

This second code sample shows how to add memory partitions into an initialized memory domain one by one.

```
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];

K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
                       K_MEM_PARTITION_P_RW_U_RW);

K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
                       K_MEM_PARTITION_P_RW_U_RO);

k_mem_domain_add_partition(&app0_domain, &app0_part0);
k_mem_domain_add_partition(&app0_domain, &app0_part1);
```

Note

The maximum number of memory partitions is limited by the maximum number of MPU regions or the maximum number of MMU tables.

Memory Domain Assignment Any thread may join a memory domain, and any memory domain may have multiple threads assigned to it. Threads are assigned to memory domains with an API call:

```
k_mem_domain_add_thread(&app0_domain, app_thread_id);
```

If the thread was already a member of some other domain (including the default domain), it will be removed from it in favor of the new one.

In addition, if a thread is a member of a memory domain, and it creates a child thread, that thread will belong to the domain as well.

Remove a Memory Partition from a Memory Domain The following code shows how to remove a memory partition from a memory domain.

```
k_mem_domain_remove_partition(&app0_domain, &app0_part1);
```

The k_mem_domain_remove_partition() API finds the memory partition that matches the given parameter and removes that partition from the memory domain.

Available Partition Attributes When defining a partition, we need to set access permission attributes to the partition. Since the access control of memory partitions relies on either an MPU or MMU, the available partition attributes would be architecture dependent.

The complete list of available partition attributes for a specific architecture is found in the architecture-specific include file `include/zephyr/arch/<arch name>/arch.h`, (for example, `include/zehpyr/arch/arm/arch.h`.) Some examples of partition attributes are:

```
/* Denote partition is privileged read/write, unprivileged read/write */
K_MEM_PARTITION_P_RW_U_RW
/* Denote partition is privileged read/write, unprivileged read-only */
K_MEM_PARTITION_P_RW_U_RO
```

In almost all cases `K_MEM_PARTITION_P_RW_U_RW` is the right choice.

Configuration Options

Related configuration options:

- CONFIG_MAX_DOMAIN_PARTITIONS

API Reference

The following memory domain APIs are provided by include/zephyr/kernel.h:

group mem_domain_apis

Defines

K_MEM_PARTITION_DEFINE(name, start, size, attr)

Statically declare a memory partition.

Functions

int k_mem_domain_init(struct *k_mem_domain* *domain, uint8_t num_parts, struct *k_mem_partition* *parts[])

Initialize a memory domain.

Initialize a memory domain with given name and memory partitions.

See documentation for *k_mem_domain_add_partition()* for details about partition constraints.

Do not call *k_mem_domain_init()* on the same memory domain more than once, doing so is undefined behavior.

Parameters

- **domain** – The memory domain to be initialized.
- **num_parts** – The number of array items of "parts" parameter.
- **parts** – An array of pointers to the memory partitions. Can be NULL if num_parts is zero.

Return values

- **0** – if successful
- **-EINVAL** – if invalid parameters supplied
- **-ENOMEM** – if insufficient memory

int k_mem_domain_add_partition(struct *k_mem_domain* *domain, struct *k_mem_partition* *part)

Add a memory partition into a memory domain.

Add a memory partition into a memory domain. Partitions must conform to the following constraints:

- Partitions in the same memory domain may not overlap each other.
- Partitions must not be defined which expose private kernel data structures or kernel objects.
- The starting address alignment, and the partition size must conform to the constraints of the underlying memory management hardware, which varies per architecture.

- Memory domain partitions are only intended to control access to memory from user mode threads.
- If CONFIG_EXECUTE_XOR_WRITE is enabled, the partition must not allow both writes and execution.

Violating these constraints may lead to CPU exceptions or undefined behavior.

Parameters

- `domain` – The memory domain to be added a memory partition.
- `part` – The memory partition to be added

Return values

- `0` – if successful
- `-EINVAL` – if invalid parameters supplied
- `-ENOSPC` – if no free partition slots available

int `k_mem_domain_remove_partition`(struct *k_mem_domain* *domain, struct *k_mem_partition* *part)

Remove a memory partition from a memory domain.

Remove a memory partition from a memory domain.

Parameters

- `domain` – The memory domain to be removed a memory partition.
- `part` – The memory partition to be removed

Return values

- `0` – if successful
- `-EINVAL` – if invalid parameters supplied
- `-ENOENT` – if no matching partition found

int `k_mem_domain_add_thread`(struct *k_mem_domain* *domain, k_tid_t thread)

Add a thread into a memory domain.

Add a thread into a memory domain. It will be removed from whatever memory domain it previously belonged to.

Parameters

- `domain` – The memory domain that the thread is going to be added into.
- `thread` – ID of thread going to be added into the memory domain.

Returns

0 if successful, fails otherwise.

Variables

struct *k_mem_domain* `k_mem_domain_default`

Default memory domain.

All threads are a member of some memory domain, even if running in supervisor mode. Threads belong to this default memory domain if they haven't been added to or inherited membership from some other domain.

This memory domain has the z_libc_partition partition for the C library added to it if exists.

struct **k_mem_partition**

#include <mem_domain.h> Memory Partition.

A memory partition is a region of memory in the linear address space with a specific access policy.

The alignment of the starting address, and the alignment of the size value may have varying requirements based on the capabilities of the underlying memory management hardware; arbitrary values are unlikely to work.

Public Members

uintptr_t **start**

start address of memory partition

size_t **size**

size of memory partition

k_mem_partition_attr_t **attr**

attribute of memory partition

struct **k_mem_domain**

#include <mem_domain.h> Memory Domain.

A memory domain is a collection of memory partitions, used to represent a user thread's access policy for the linear address space. A thread may be a member of only one memory domain, but any memory domain may have multiple threads that are members.

Supervisor threads may also be a member of a memory domain; this has no implications on their memory access but can be useful as any child threads inherit the memory domain membership of the parent.

A user thread belonging to a memory domain with no active partitions will have guaranteed access to its own stack buffer, program text, and read-only data.

Public Members

struct *k_mem_partition* **partitions**[CONFIG_MAX_DOMAIN_PARTITIONS]

partitions in the domain

sys_dlist_t **mem_domain_q**

Doubly linked list of member threads.

uint8_t **num_partitions**

number of active partitions in the domain

3.3.3 Kernel Objects

A kernel object can be one of three classes of data:

- A core kernel object, such as a semaphore, thread, pipe, etc.

- A thread stack, which is an array of `z_thread_stack_element` and declared with *K_THREAD_STACK_DEFINE()*
- A device driver instance (const struct device) that belongs to one of a defined set of subsystems

The set of known kernel objects and driver subsystems is defined in include/kernel.h as `k_objects`.

Kernel objects are completely opaque to user threads. User threads work with addresses to kernel objects when making API calls, but may never dereference these addresses, doing so will cause a memory protection fault. All kernel objects must be placed in memory that is not accessible by user threads.

Since user threads may not directly manipulate kernel objects, all use of them must go through system calls. In order to perform a system call on a kernel object, checks are performed by system call handler functions that the kernel object address is valid and that the calling thread has sufficient permissions to work with it.

Permission on an object also has the semantics of a reference to an object. This is significant for certain object APIs which do temporary allocations, or objects which themselves have been allocated from a runtime memory pool.

If an object loses all references, two events may happen:

- If the object has an associated cleanup function, the cleanup function may be called to release any runtime-allocated buffers the object was using.
- If the object itself was dynamically allocated, the memory for the object will be freed.

Object Placement

Kernel objects that are only used by supervisor threads have no restrictions and can be located anywhere in the binary, or even declared on stacks. However, to prevent accidental or intentional corruption by user threads, they must not be located in any memory that user threads have direct access to.

In order for a static kernel object to be usable by a user thread via system call APIs, several conditions must be met on how the kernel object is declared:

- The object must be declared as a top-level global at build time, such that it appears in the ELF symbol table. It is permitted to declare kernel objects with static scope. The post-build script *scripts/build/gen_kobject_list.py* scans the generated ELF file to find kernel objects and places their memory addresses in a special table of kernel object metadata. Kernel objects may be members of arrays or embedded within other data structures.
- Kernel objects must be located in memory reserved for the kernel. They must not be located in any memory partitions that are user-accessible.
- Any memory reserved for a kernel object must be used exclusively for that object. Kernel objects may not be members of a union data type.

Kernel objects that are found but do not meet the above conditions will not be included in the generated table that is used to validate kernel object pointers passed in from user mode.

The debug output of the *scripts/build/gen_kobject_list.py* script may be useful when debugging why some object was unexpectedly not being tracked. This information will be printed if the script is run with the `--verbose` flag, or if the build system is invoked with verbose output.

Dynamic Objects

Kernel objects may also be allocated at runtime if `CONFIG_DYNAMIC_OBJECTS` is enabled. In this case, the *k_object_alloc()* API may be used to instantiate an object from the calling thread's

resource pool. Such allocations may be freed in two ways:

- Supervisor threads may call *k_object_free()* to force a dynamic object to be released.
- If an object's references drop to zero (which happens when no threads have permissions on it) the object will be automatically freed. User threads may drop their own permission on an object with *k_object_release()*, and their permissions are automatically cleared when a thread terminates. Supervisor threads may additionally revoke references for another thread using *k_object_access_revoke()*.

Because permissions are also used for reference counting, it is important for supervisor threads to acquire permissions on objects they are using even though the access control aspects of the permission system are not enforced.

Implementation Details The *scripts/build/gen_kobject_list.py* script is a post-build step which finds all the valid kernel object instances in the binary. It accomplishes this by parsing the DWARF debug information present in the generated ELF file for the kernel.

Any instances of structs or arrays corresponding to kernel objects that meet the object placement criteria will have their memory addresses placed in a special perfect hash table of kernel objects generated by the 'gperf' tool. When a system call is made and the kernel is presented with a memory address of what may or may not be a valid kernel object, the address can be validated with a constant-time lookup in this table.

Drivers are a special case. All drivers are instances of *device*, but it is important to know what subsystem a driver belongs to so that incorrect operations, such as calling a UART API on a sensor driver object, can be prevented. When a device struct is found, its API pointer is examined to determine what subsystem the driver belongs to.

The table itself maps kernel object memory addresses to instances of `z_object`, which has all the metadata for that object. This includes:

- A bitfield indicating permissions on that object. All threads have a numerical ID assigned to them at build time, used to index the permission bitfield for an object to see if that thread has permission on it. The size of this bitfield is controlled by the `CONFIG_MAX_THREAD_BYTES` option and the build system will generate an error if this value is too low.
- A type field indicating what kind of object this is, which is some instance of `k_objects`.
- A set of flags for that object. This is currently used to track initialization state and whether an object is public or not.
- An extra data field. The semantics of this field vary by object type, see the definition of `z_object_data`.

Dynamic objects allocated at runtime are tracked in a runtime red/black tree which is used in parallel to the gperf table when validating object pointers.

Supervisor Thread Access Permission

Supervisor threads can access any kernel object. However, permissions for supervisor threads are still tracked for two reasons:

- If a supervisor thread calls *k_thread_user_mode_enter()*, the thread will then run in user mode with any permissions it had been granted (in many cases, by itself) when it was a supervisor thread.
- If a supervisor thread creates a user thread with the *K_INHERIT_PERMS* option, the child thread will be granted the same permissions as the parent thread, except the parent thread object.

User Thread Access Permission

By default, when a user thread is created, it will only have access permissions on its own thread object. Other kernel objects by default are not usable. Access to them needs to be explicitly or implicitly granted. There are several ways to do this.

- If a thread is created with the *K_INHERIT_PERMS*, that thread will inherit all the permissions of the parent thread, except the parent thread object.
- A thread that has permission on an object, or is running in supervisor mode, may grant permission on that object to another thread via the *k_object_access_grant()* API. The convenience pseudo-function *k_thread_access_grant()* may also be used, which accepts an arbitrary number of pointers to kernel objects and calls *k_object_access_grant()* on each of them. The thread being granted permission, or the object whose access is being granted, do not need to be in an initialized state. If the caller is from user mode, the caller must have permissions on both the kernel object and the target thread object.
- Supervisor threads may declare a particular kernel object to be a public object, usable by all current and future threads with the *k_object_access_all_grant()* API. You must assume that any untrusted or exploited code will then be able to access the object. Use this API with caution!
- If a thread was declared statically with *K_THREAD_DEFINE()*, then the *K_THREAD_ACCESS_GRANT()* may be used to grant that thread access to a set of kernel objects at boot time.

Once a thread has been granted access to an object, such access may be removed with the *k_object_access_revoke()* API. This API is not available to user threads, however user threads may use *k_object_release()* to relinquish their own permissions on an object.

API calls from supervisor mode to set permissions on kernel objects that are not being tracked by the kernel will be no-ops. Doing the same from user mode will result in a fatal error for the calling thread.

Objects allocated with *k_object_alloc()* implicitly grant permission on the allocated object to the calling thread.

Initialization State

Most operations on kernel objects will fail if the object is considered to be in an uninitialized state. The appropriate init function for the object must be performed first.

Some objects will be implicitly initialized at boot:

- Kernel objects that were declared with static initialization macros (such as *K_SEM_DEFINE* for semaphores) will be in an initialized state at build time.
- Device driver objects are considered initialized after their init function is run by the kernel early in the boot process.

If a kernel object is initialized with a private static initializer, the object must have `k_object_init()` called on it at some point by a supervisor thread, otherwise the kernel will consider the object uninitialized if accessed by a user thread. This is very uncommon, typically only for kernel objects that are embedded within some larger struct and initialized statically.

```
struct foo {
    struct k_sem sem;
    ...
};

struct foo my_foo = {
    .sem = Z_SEM_INITIALIZER(my_foo.sem, 0, 1),
```

(continues on next page)

(continued from previous page)

```
    ...
};

...
k_object_init(&my_foo.sem);
...
```

Creating New Kernel Object Types

When implementing new kernel features or driver subsystems, it may be necessary to define some new kernel object types. There are different steps needed for creating core kernel objects and new driver subsystems.

Creating New Core Kernel Objects

- In `scripts/build/gen_kobject_list.py`, add the name of the struct to the `kobjects` list.

Instances of the new struct should now be tracked.

Creating New Driver Subsystem Kernel Objects All driver instances are *device*. They are differentiated by what API struct they are set to.

- In `scripts/build/gen_kobject_list.py`, add the name of the API struct for the new subsystem to the `subsystems` list.

Driver instances of the new subsystem should now be tracked.

Configuration Options

Related configuration options:

- `CONFIG_USERSPACE`
- `CONFIG_MAX_THREAD_BYTES`

API Reference

group `usermode_apis`

Defines

`K_THREAD_ACCESS_GRANT`(name_, ...)

Grant a static thread access to a list of kernel objects.

For threads declared with *K_THREAD_DEFINE()*, grant the thread access to a set of kernel objects. These objects do not need to be in an initialized state. The permissions will be granted when the threads are initialized in the early boot sequence.

All arguments beyond the first must be pointers to kernel objects.

Parameters

- `name_` – Name of the thread, as passed to *K_THREAD_DEFINE()*

K_OBJ_FLAG_INITIALIZED
: Object initialized.

K_OBJ_FLAG_PUBLIC
: Object is Public.

K_OBJ_FLAG_ALLOC
: Object allocated.

K_OBJ_FLAG_DRIVER
: Driver Object.

Functions

void **k_object_access_grant**(const void *object, struct *k_thread* *thread)
: Grant a thread access to a kernel object.

  The thread will be granted access to the object if the caller is from supervisor mode, or the caller is from user mode AND has permissions on both the object and the thread whose access is being granted.

  Parameters

  - **object** – Address of kernel object
  - **thread** – Thread to grant access to the object

void **k_object_access_revoke**(const void *object, struct *k_thread* *thread)
: Revoke a thread's access to a kernel object.

  The thread will lose access to the object if the caller is from supervisor mode, or the caller is from user mode AND has permissions on both the object and the thread whose access is being revoked.

  Parameters

  - **object** – Address of kernel object
  - **thread** – Thread to remove access to the object

void **k_object_release**(const void *object)
: Release an object.

  Allows user threads to drop their own permission on an object Their permissions are automatically cleared when a thread terminates.

  Parameters

  - **object** – The object to be released

void **k_object_access_all_grant**(const void *object)
: Grant all present and future threads access to an object.

  If the caller is from supervisor mode, or the caller is from user mode and have sufficient permissions on the object, then that object will have permissions granted to it for *all* current and future threads running in the system, effectively becoming a public kernel object.

  Use of this API should be avoided on systems that are running untrusted code as it is possible for such code to derive the addresses of kernel objects and perform unwanted operations on them.

It is not possible to revoke permissions on public objects; once public, any thread may use it.

Parameters

- **object** – Address of kernel object

bool **k_object_is_valid**(const void *obj, enum k_objects otype)

Check if a kernel object is of certain type and is valid.

This checks if the kernel object exists, of certain type, and has been initialized.

Parameters

- **obj** – Address of the kernel object
- **otype** – Object type (use K_OBJ_ANY for ignoring type checking)

Returns

True if kernel object (*obj*) exists, of certain type, and has been initialized. False otherwise.

void *__k_object_alloc__(enum k_objects otype)

Allocate a kernel object of a designated type.

This will instantiate at runtime a kernel object of the specified type, returning a pointer to it. The object will be returned in an uninitialized state, with the calling thread being granted permission on it. The memory for the object will be allocated out of the calling thread's resource pool.

Note

This function is available only if CONFIG_DYNAMIC_OBJECTS is selected.

Note

Thread stack object has to use *k_object_alloc_size()* since stacks may have different sizes.

Parameters

- **otype** – Requested kernel object type

Returns

A pointer to the allocated kernel object, or NULL if memory wasn't available

void *__k_object_alloc_size__(enum k_objects otype, size_t size)

Allocate a kernel object of a designated type and a given size.

This will instantiate at runtime a kernel object of the specified type, returning a pointer to it. The object will be returned in an uninitialized state, with the calling thread being granted permission on it. The memory for the object will be allocated out of the calling thread's resource pool.

This function is specially helpful for thread stack objects because their sizes can vary. Other objects should probably look *k_object_alloc()*.

Note

This function is available only if CONFIG_DYNAMIC_OBJECTS is selected.

Parameters

- **otype** – Requested kernel object type
- **size** – Requested kernel object size

Returns
A pointer to the allocated kernel object, or NULL if memory wasn't available

void **k_object_free**(void *obj)

Free a kernel object previously allocated with *k_object_alloc()*

This will return memory for a kernel object back to resource pool it was allocated from. Care must be exercised that the object will not be used during or after when this call is made.

> **Note**
> This function is available only if CONFIG_DYNAMIC_OBJECTS is selected.

Parameters

- **obj** – Pointer to the kernel object memory address.

3.3.4 System Calls

User threads run with a reduced set of privileges than supervisor threads: certain CPU instructions may not be used, and they have access to only a limited part of the memory map. System calls (may) allow user threads to perform operations not directly available to them.

When defining system calls, it is very important to ensure that access to the API's private data is done exclusively through system call interfaces. Private kernel data should never be made available to user mode threads directly. For example, the k_queue APIs were intentionally not made available as they store bookkeeping information about the queue directly in the queue buffers which are visible from user mode.

APIs that allow the user to register callback functions that run in supervisor mode should never be exposed as system calls. Reserve these for supervisor-mode access only.

This section describes how to declare new system calls and discusses a few implementation details relevant to them.

Components

All system calls have the following components:

- A **C prototype** prefixed with __syscall for the API. It will be declared in some header under include/ or in another SYSCALL_INCLUDE_DIRS directory. This prototype is never implemented manually, instead it gets created by the *scripts/build/gen_syscalls.py* script. What gets generated is an inline function which either calls the implementation function directly (if called from supervisor mode) or goes through privilege elevation and validation steps (if called from user mode).
- An **implementation function**, which is the real implementation of the system call. The implementation function may assume that all parameters passed in have been validated if it was invoked from user mode.
- A **verification function**, which wraps the implementation function and does validation of all the arguments passed in.

- An **unmarshalling function**, which is an automatically generated handler that must be included by user source code.

C Prototype

The C prototype represents how the API is invoked from either user or supervisor mode. For example, to initialize a semaphore:

```
__syscall void k_sem_init(struct k_sem *sem, unsigned int initial_count,
                          unsigned int limit);
```

The `__syscall` attribute is very special. To the C compiler, it simply expands to 'static inline'. However to the post-build *scripts/build/parse_syscalls.py* script, it indicates that this API is a system call. The *scripts/build/parse_syscalls.py* script does some parsing of the function prototype, to determine the data types of its return value and arguments, and has some limitations:

- Array arguments must be passed in as pointers, not arrays. For example, `int foo[]` or `int foo[12]` is not allowed, but should instead be expressed as `int *foo`.
- Function pointers horribly confuse the limited parser. The workaround is to typedef them first, and then express in the argument list in terms of that typedef.
- `__syscall` must be the first thing in the prototype.

The preprocessor is intentionally not used when determining the set of system calls to generate. However, any generated system calls that don't actually have a verification function defined (because the related feature is not enabled in the kernel configuration) will instead point to a special verification for unimplemented system calls. Data type definitions for APIs should not have conditional visibility to the compiler.

Any header file that declares system calls must include a special generated header at the very bottom of the header file. This header follows the naming convention `syscalls/<name of header file>`. For example, at the bottom of `include/sensor.h`:

```
#include <zephyr/syscalls/sensor.h>
```

C prototype functions must be declared in one of the directories listed in the CMake variable `SYSCALL_INCLUDE_DIRS`. This list always contains `APPLICATION_SOURCE_DIR` when `CONFIG_APPLICATION_DEFINED_SYSCALL` is set, or `${ZEPHYR_BASE}/subsys/testsuite/ztest/include` when `CONFIG_ZTEST` is set. Additional paths can be added to the list through the CMake command line or in CMake code that is run before `find_package(Zephyr ...)` is run. `${ZEPHYR_BASE}/include` is always scanned for potential syscall prototypes.

Note that not all syscalls will be included in the final binaries. CMake functions `zephyr_syscall_header` and `zephyr_syscall_header_ifdef` are used to specify which header files contain syscall prototypes where those syscalls must be present in the final binaries. Note that header files inside directories listed in CMake variable `SYSCALL_INCLUDE_DIRS` will always have their syscalls present in final binaries. To force all syscalls to be included in the final binaries, turn on `CONFIG_EMIT_ALL_SYSCALLS`.

Invocation Context Source code that uses system call APIs can be made more efficient if it is known that all the code inside a particular C file runs exclusively in user mode, or exclusively in supervisor mode. The system will look for the definition of macros `__ZEPHYR_SUPERVISOR__` or `__ZEPHYR_USER__`, typically these will be added to the compiler flags in the build system for the related files.

- If `CONFIG_USERSPACE` is not enabled, all APIs just directly call the implementation function.
- Otherwise, the default case is to make a runtime check to see if the processor is currently running in user mode, and either make the system call or directly call the implementation function as appropriate.

- If __ZEPHYR_SUPERVISOR__ is defined, then it is assumed that all the code runs in supervisor mode and all APIs just directly call the implementation function. If the code was actually running in user mode, there will be a CPU exception as soon as it tries to do something it isn't allowed to do.
- If __ZEPHYR_USER__ is defined, then it is assumed that all the code runs in user mode and system calls are unconditionally made.

Implementation Details Declaring an API with `__syscall` causes some code to be generated in C and header files by the *scripts/build/gen_syscalls.py* script, all of which can be found in the project out directory under `include/generated/`:

- The system call is added to the enumerated type of system call IDs, which is expressed in `include/generated/zephyr/syscall_list.h`. It is the name of the API in uppercase, prefixed with `K_SYSCALL_`.
- An entry for the system call is created in the dispatch table `_k_syscall_table`, expressed in `include/generated/zephyr/syscall_dispatch.c`
  - This table only contains syscalls where their corresponding prototypes are declared in header files when `CONFIG_EMIT_ALL_SYSCALLS` is enabled:
    * Indicated by CMake functions `zephyr_syscall_header` and `zephyr_syscall_header_ifdef`, or
    * Under directories specified in CMake variable `SYSCALL_INCLUDE_DIRS`.
- A weak verification function is declared, which is just an alias of the 'unimplemented system call' verifier. This is necessary since the real verification function may or may not be built depending on the kernel configuration. For example, if a user thread makes a sensor subsystem API call, but the sensor subsystem is not enabled, the weak verifier will be invoked instead.
- An unmarshalling function is defined in `include/generated/<name>_mrsh.c`

The body of the API is created in the generated system header. Using the example of *k_sem_init()*, this API is declared in `include/kernel.h`. At the bottom of `include/kernel.h` is:

```
#include <zephyr/syscalls/kernel.h>
```

Inside this header is the body of *k_sem_init()*:

```
static inline void k_sem_init(struct k_sem * sem, unsigned int initial_count, unsigned int␣
↪limit)
{
#ifdef CONFIG_USERSPACE
        if (z_syscall_trap()) {
                arch_syscall_invoke3(*(uintptr_t *)&sem, *(uintptr_t *)&initial_count,␣
↪*(uintptr_t *)&limit, K_SYSCALL_K_SEM_INIT);
                return;
        }
        compiler_barrier();
#endif
        z_impl_k_sem_init(sem, initial_count, limit);
}
```

This generates an inline function that takes three arguments with void return value. Depending on context it will either directly call the implementation function or go through a system call elevation. A prototype for the implementation function is also automatically generated.

The final layer is the invocation of the system call itself. All architectures implementing system calls must implement the seven inline functions `_arch_syscall_invoke0()` through `_arch_syscall_invoke6()`. These functions marshal arguments into designated CPU registers

and perform the necessary privilege elevation. Parameters of API inline function, before being passed as arguments to system call, are C casted to `uintptr_t` which matches size of register. Exception to above is passing 64-bit parameters on 32-bit systems, in which case 64-bit parameters are split into lower and higher part and passed as two consecutive arguments. There is always a `uintptr_t` type return value, which may be neglected if not needed.

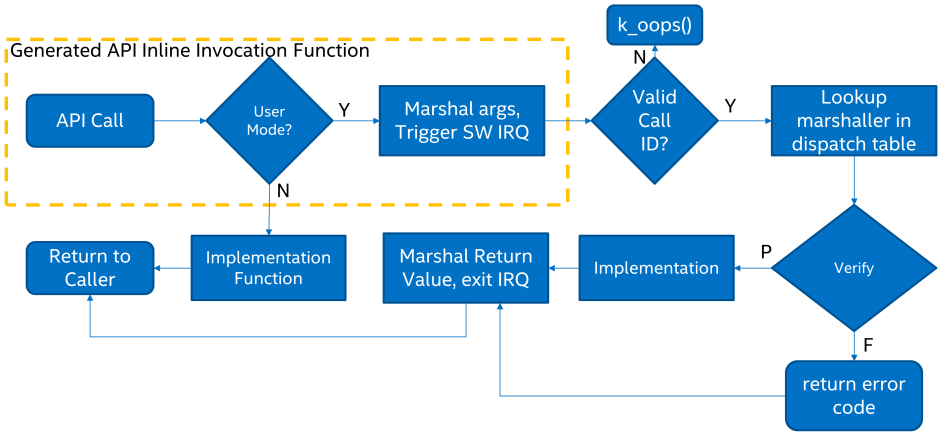


Fig. 3: System Call execution flow

Some system calls may have more than six arguments, but number of arguments passed via registers is limited to six for all architectures. Additional arguments will need to be passed in an array in the source memory space, which needs to be treated as untrusted memory in the verification function. This code (packing, unpacking and validation) is generated automatically as needed in the stub above and in the unmarshalling function.

System calls return `uintptr_t` type value that is C casted, by wrapper, to a return type of API prototype declaration. This means that 64-bit value may not be directly returned, from a system call to its wrapper, on 32-bit systems. To solve the problem the automatically generated wrapper function defines 64-bit intermediate variable, which is considered **untrusted** buffer, on its stack and passes pointer to that variable to the system call, as a final argument. Upon return from the system call the value written to that buffer will be returned by the wrapper function. The problem does not exist on 64-bit systems which are able to return 64-bit values directly.

Implementation Function

The implementation function is what actually does the work for the API. Zephyr normally does little to no error checking of arguments, or does this kind of checking with assertions. When writing the implementation function, validation of any parameters is optional and should be done with assertions.

All implementation functions must follow the naming convention, which is the name of the API prefixed with `z_impl_`. Implementation functions may be declared in the same header as the API as a static inline function or declared in some C file. There is no prototype needed for implementation functions, these are automatically generated.

Verification Function

The verification function runs on the kernel side when a user thread makes a system call. When the user thread makes a software interrupt to elevate to supervisor mode, the common system call entry point uses the system call ID provided by the user to look up the appropriate unmarshalling function for that system call and jump into it. This in turn calls the verification function.

Verification and unmarshalling functions only run when system call APIs are invoked from user mode. If an API is invoked from supervisor mode, the implementation is simply called and there is no software trap.

The purpose of the verification function is to validate all the arguments passed in. This includes:

- Any kernel object pointers provided. For example, the semaphore APIs must ensure that the semaphore object passed in is a valid semaphore and that the calling thread has permission on it.
- Any memory buffers passed in from user mode. Checks must be made that the calling thread has read or write permissions on the provided buffer.
- Any other arguments that have a limited range of valid values.

Verification functions involve a great deal of boilerplate code which has been made simpler by some macros in include/zephyr/internal/syscall_handler.h. Verification functions should be declared using these macros.

Argument Validation Several macros exist to validate arguments:

- `K_SYSCALL_OBJ()` Checks a memory address to assert that it is a valid kernel object of the expected type, that the calling thread has permissions on it, and that the object is initialized.
- `K_SYSCALL_OBJ_INIT()` is the same as `K_SYSCALL_OBJ()`, except that the provided object may be uninitialized. This is useful for verifiers of object init functions.
- `K_SYSCALL_OBJ_NEVER_INIT()` is the same as `K_SYSCALL_OBJ()`, except that the provided object must be uninitialized. This is not used very often, currently only for *k_thread_create()*.
- `K_SYSCALL_MEMORY_READ()` validates a memory buffer of a particular size. The calling thread must have read permissions on the entire buffer.
- `K_SYSCALL_MEMORY_WRITE()` is the same as `K_SYSCALL_MEMORY_READ()` but the calling thread must additionally have write permissions.
- `K_SYSCALL_MEMORY_ARRAY_READ()` validates an array whose total size is expressed as separate arguments for the number of elements and the element size. This macro correctly accounts for multiplication overflow when computing the total size. The calling thread must have read permissions on the total size.
- `K_SYSCALL_MEMORY_ARRAY_WRITE()` is the same as `K_SYSCALL_MEMORY_ARRAY_READ()` but the calling thread must additionally have write permissions.
- `K_SYSCALL_VERIFY_MSG()` does a runtime check of some boolean expression which must evaluate to true otherwise the check will fail. A variant `K_SYSCALL_VERIFY` exists which does not take a message parameter, instead printing the expression tested if it fails. The latter should only be used for the most obvious of tests.
- `K_SYSCALL_DRIVER_OP()` checks at runtime if a driver instance is capable of performing a particular operation. While this macro can be used by itself, it's mostly a building block for macros that are automatically generated for every driver subsystem. For instance, to validate the GPIO driver, one could use the `K_SYSCALL_DRIVER_GPIO()` macro.
- `K_SYSCALL_SPECIFIC_DRIVER()` is a runtime check to verify that a provided pointer is a valid instance of a specific device driver, that the calling thread has permissions on it, and that the driver has been initialized. It does this by checking the API structure pointer that is stored within the driver instance and ensuring that it matches the provided value, which should be the address of the specific driver's API structure.

If any check fails, the macros will return a nonzero value. The macro `K_OOPS()` can be used to induce a kernel oops which will kill the calling thread. This is done instead of returning some error condition to keep the APIs the same when calling from supervisor mode.

Verifier Definition All system calls are dispatched to a verifier function with a prefixed `z_vrfy_` name based on the system call. They have exactly the same return type and argument types as the wrapped system call. Their job is to execute the system call (generally by calling the implementation function) after having validated all arguments.

The verifier is itself invoked by an automatically generated unmarshaller function which takes care of unpacking the register arguments from the architecture layer and casting them to the correct type. This is defined in a header file that must be included from user code, generally somewhere after the definition of the verifier in a translation unit (so that it can be inlined).

For example:

```
static int z_vrfy_k_sem_take(struct k_sem *sem, int32_t timeout)
{
    K_OOPS(K_SYSCALL_OBJ(sem, K_OBJ_SEM));
    return z_impl_k_sem_take(sem, timeout);
}
#include <zephyr/syscalls/k_sem_take_mrsh.c>
```

Verification Memory Access Policies Parameters passed to system calls by reference require special handling, because the value of these parameters can be changed at any time by any user thread that has access to the memory that parameter points to. If the kernel makes any logical decisions based on the contents of this memory, this can open up the kernel to attacks even if checking is done. This is a class of exploits known as TOCTOU (Time Of Check to Time Of Use).

The proper procedure to mitigate these attacks is to make a copies in the verification function, and only perform parameter checks on the copies, which user threads will never have access to. The implementation functions get passed the copy and not the original data sent by the user. The `k_usermode_to_copy()` and `k_usermode_from_copy()` APIs exist for this purpose.

There is one exception in place, with respect to large data buffers which are only used to provide a memory area that is either only written to, or whose contents are never used for any validation or control flow. Further discussion of this later in this section.

As a first example, consider a parameter which is used as an output parameter for some integral value:

```
int z_vrfy_some_syscall(int *out_param)
{
    int local_out_param;
    int ret;

    ret = z_impl_some_syscall(&local_out_param);
    K_OOPS(k_usermode_to_copy(out_param, &local_out_param, sizeof(*out_param)));
    return ret;
}
```

Here we have allocated `local_out_param` on the stack, passed its address to the implementation function, and then used `k_usermode_to_copy()` to fill in the memory passed in by the caller.

It might be tempting to do something more concise:

```
int z_vrfy_some_syscall(int *out_param)
{
    K_OOPS(K_SYSCALL_MEMORY_WRITE(out_param, sizeof(*out_param)));
    return z_impl_some_syscall(out_param);
}
```

However, this is unsafe if the implementation ever does any reads to this memory as part of its logic. For example, it could be used to store some counter value, and this could be meddled with by user threads that have access to its memory. It is by far safest for small integral values to do the copying as shown in the first example.

Some parameters may be input/output. For instance, it's not uncommon to see APIs which pass in a pointer to some `size_t` which is a maximum allowable size, which is then updated by the implementation to reflect the actual number of bytes processed. This too should use a stack copy:

```
int z_vrfy_in_out_syscall(size_t *size_ptr)
{
    size_t size;
    int ret;

    K_OOPS(k_usermode_from_copy(&size, size_ptr, sizeof(size));
    ret = z_impl_in_out_syscall(&size);
    K_OOPS(k_usermode_to_copy(size_ptr, &size, sizeof(size)));
    return ret;
}
```

Many system calls pass in structures or even linked data structures. All should be copied. Typically this is done by allocating copies on the stack:

```
struct bar {
    ...
};

struct foo {
    ...
    struct bar *bar_left;
    struct bar *bar_right;
};

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar bar_right_copy;
    struct bar bar_left_copy;

    K_OOPS(k_usermode_from_copy(&foo_copy, foo, sizeof(*foo)));
    K_OOPS(k_usermode_from_copy(&bar_right_copy, foo_copy.bar_right,
                            sizeof(struct bar)));
    foo_copy.bar_right = &bar_right_copy;
    K_OOPS(k_usermode_from_copy(&bar_left_copy, foo_copy.bar_left,
                            sizeof(struct bar)));
    foo_copy.bar_left = &bar_left_copy;

    return z_impl_must_alloc(&foo_copy);
}
```

In some cases the amount of data isn't known at compile time or may be too large to allocate on the stack. In this scenario, it may be necessary to draw memory from the caller's resource pool via `z_thread_malloc()`. This should always be considered last resort. Functional safety programming guidelines heavily discourage usage of heap and the fact that a resource pool is used must be clearly documented. Any issues with allocation must be reported, to a caller, with returning the `-ENOMEM` . The `K_OOPS()` should never be used to verify if resource allocation has been successful.

```
struct bar {
    ...
};

struct foo {
    size_t count;
    struct bar *bar_list; /* array of struct bar of size count */
};
```

(continues on next page)

(continued from previous page)

```
int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar *bar_list_copy;
    size_t bar_list_bytes;

    /* Safely copy foo into foo_copy */
    K_OOPS(k_usermode_from_copy(&foo_copy, foo, sizeof(*foo)));

    /* Bounds check the count member, in the copy we made */
    if (foo_copy.count > 32) {
        return -EINVAL;
    }

    /* Allocate RAM for the bar_list, replace the pointer in
     * foo_copy */
    bar_list_bytes = foo_copy.count * sizeof(struct_bar);
    bar_list_copy = z_thread_malloc(bar_list_bytes);
    if (bar_list_copy == NULL) {
        return -ENOMEM;
    }
    K_OOPS(k_usermode_from_copy(bar_list_copy, foo_copy.bar_list,
                                bar_list_bytes));
    foo_copy.bar_list = bar_list_copy;

    ret = z_impl_must_alloc(&foo_copy);

    /* All done with the memory, free it and return */
    k_free(foo_copy.bar_list_copy);
    return ret;
}
```

Finally, we must consider large data buffers. These represent areas of user memory which either have data copied out of, or copied into. It is permitted to pass these pointers to the implementation function directly. The caller's access to the buffer still must be validated with K_SYSCALL_MEMORY APIs. The following constraints need to be met:

- If the buffer is used by the implementation function to write data, such as data captured from some MMIO region, the implementation function must only write this data, and never read it.
- If the buffer is used by the implementation function to read data, such as a block of memory to write to some hardware destination, this data must be read without any processing. No conditional logic can be implemented due to the data buffer's contents. If such logic is required a copy must be made.
- The buffer must only be used synchronously with the call. The implementation must not ever save the buffer address and use it asynchronously, such as when an interrupt fires.

```
int z_vrfy_get_data_from_kernel(void *buf, size_t size)
{
    K_OOPS(K_SYSCALL_MEMORY_WRITE(buf, size));
    return z_impl_get_data_from_kernel(buf, size);
}
```

Verification Return Value Policies When verifying system calls, it's important to note which kinds of verification failures should propagate a return value to the caller, and which should simply invoke K_OOPS() which kills the calling thread. The current conventions are as follows:

1. For system calls that are defined but not compiled, invocations of these missing system calls are routed to `handler_no_syscall()` which invokes `K_OOPS()`.
2. Any invalid access to memory found by the set of `K_SYSCALL_MEMORY` APIs, `k_usermode_from_copy()`, `k_usermode_to_copy()` should trigger a `K_OOPS`. This happens when the caller doesn't have appropriate permissions on the memory buffer or some size calculation overflowed.
3. Most system calls take kernel object pointers as an argument, checked either with one of the `K_SYSCALL_OBJ` functions, `K_SYSCALL_DRIVER_nnnnn`, or manually using `k_object_validate()`. These can fail for a variety of reasons: missing driver API, bad kernel object pointer, wrong kernel object type, or improper initialization state. These issues should always invoke `K_OOPS()`.
4. Any error resulting from a failed memory heap allocation, often from invoking `z_thread_malloc()`, should propagate `-ENOMEM` to the caller.
5. General parameter checks should be done in the implementation function, in most cases using `CHECKIF()`.
   - The behavior of `CHECKIF()` depends on the kernel configuration, but if user mode is enabled, `CONFIG_RUNTIME_ERROR_CHECKS` is enforced, which guarantees that these checks will be made and a return value propagated.
6. It is totally forbidden for any kind of kernel mode callback function to be registered from user mode. APIs which simply install callbacks shall not be exposed as system calls. Some driver subsystem APIs may take optional function callback pointers. User mode verification functions for these APIs must enforce that these are NULL and should invoke `K_OOPS()` if not.
7. Some parameter checks are enforced only from user mode. These should be checked in the verification function and propagate a return value to the caller if possible.

There are some known exceptions to these policies currently in Zephyr:

- *`k_thread_join()`* and *`k_thread_abort()`* are no-ops if the thread object isn't initialized. This is because for threads, the initialization bit pulls double-duty to indicate whether a thread is running, cleared upon exit. See #23030.
- *`k_thread_create()`* invokes `K_OOPS()` for parameter checks, due to a great deal of existing code ignoring the return value. This will also be addressed by #23030.
- *`k_thread_abort()`* invokes `K_OOPS()` if an essential thread is aborted, as the function has no return value.
- Various system calls related to logging invoke `K_OOPS()` when bad parameters are passed in as they do not propagate errors.

Configuration Options

Related configuration options:

- `CONFIG_USERSPACE`

APIs

Helper macros for creating system call verification functions are provided in include/zephyr/internal/syscall_handler.h:

- `K_SYSCALL_OBJ()`
- `K_SYSCALL_OBJ_INIT()`

- K_SYSCALL_OBJ_NEVER_INIT()
- K_OOPS()
- K_SYSCALL_MEMORY_READ()
- K_SYSCALL_MEMORY_WRITE()
- K_SYSCALL_MEMORY_ARRAY_READ()
- K_SYSCALL_MEMORY_ARRAY_WRITE()
- K_SYSCALL_VERIFY_MSG()
- K_SYSCALL_VERIFY

Functions for invoking system calls are defined in include/zephyr/syscall.h:

- _arch_syscall_invoke0()
- _arch_syscall_invoke1()
- _arch_syscall_invoke2()
- _arch_syscall_invoke3()
- _arch_syscall_invoke4()
- _arch_syscall_invoke5()
- _arch_syscall_invoke6()

3.3.5 MPU Stack Objects

Thread Stack Creation

Thread stacks are declared statically with *K_THREAD_STACK_DEFINE()*.

For architectures which utilize memory protection unit (MPU) hardware, stacks are physically contiguous allocations. This contiguous allocation has implications for the placement of stacks in memory, as well as the implementation of other features such as stack protection and userspace. The implications for placement are directly attributed to the alignment requirements for MPU regions. This is discussed in the memory placement section below.

Stack Guards

Stack protection mechanisms require hardware support that can restrict access to memory. Memory protection units can provide this kind of support. The MPU provides a fixed number of regions. Each region contains information about the start, end, size, and access attributes to be enforced on that particular region.

Stack guards are implemented by using a single MPU region and setting the attributes for that region to not allow write access. If invalid accesses occur, a fault ensues. The stack guard is defined at the bottom (the lowest address) of the stack.

Memory Placement

During stack creation, a set of constraints are enforced on the allocation of memory. These constraints include determining the alignment of the stack and the correct sizing of the stack. During linking of the binary, these constraints are used to place the stacks properly.

The main source of the memory constraints is the MPU design for the SoC. The MPU design may require specific constraints on the region definition. These can include alignment of beginning and end addresses, sizes of allocations, or even interactions between overlapping regions.

Some MPUs require that each region be aligned to a power of two. These SoCs will have CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT defined. This means that a 1500 byte stack should be aligned to a 2kB boundary and the stack size should also be adjusted to 2kB to ensure that nothing else is placed in the remainder of the region. SoCs which include the unmodified ARM v7m MPU will have these constraints.

Some ARM MPUs use start and end addresses to define MPU regions and both the start and end addresses require 32 byte alignment. An example of this kind of MPU is found in the NXP FRDM K64F.

MPUs may have a region priority mechanisms that use the highest priority region that covers the memory access to determine the enforcement policy. Others may logically OR regions to determine enforcement policy.

Size and alignment constraints may result in stack allocations being larger than the requested size. Region priority mechanisms may result in some added complexity when implementing stack guards.

3.3.6 MPU Backed Userspace

The MPU backed userspace implementation requires the creation of a secondary set of stacks. These stacks exist in a 1:1 relationship with each thread stack defined in the system. The privileged stacks are created as a part of the build process.

A post-build script *scripts/build/gen_kobject_list.py* scans the generated ELF file and finds all of the thread stack objects. A set of privileged stacks, a lookup table, and a set of helper functions are created and added to the image.

During the process of dropping a thread to user mode, the privileged stack information is filled in and later used by the swap and system call infrastructure to configure the MPU regions properly for the thread stack and guard (if applicable).

During system calls, the user mode thread's access to the system call and the passed-in parameters are all validated. The user mode thread is then elevated to privileged mode, the stack is switched to use the privileged stack, and the call is made to the specified kernel API. On return from the kernel API, the thread is set back to user mode and the stack is restored to the user stack.

3.4 Memory Management

The following contains various topics regarding memory management.

3.4.1 Memory Heaps

Zephyr provides a collection of utilities that allow threads to dynamically allocate memory.

Synchronized Heap Allocator

Creating a Heap The simplest way to define a heap is statically, with the *K_HEAP_DEFINE* macro. This creates a static *k_heap* variable with a given name that manages a memory region of the specified size.

Heaps can also be created to manage arbitrary regions of application-controlled memory using *k_heap_init()*.

Allocating Memory Memory can be allocated from a heap using *k_heap_alloc()*, passing it the address of the heap object and the number of bytes desired. This functions similarly to standard C `malloc()`, returning a NULL pointer on an allocation failure.

The heap supports blocking operation, allowing threads to go to sleep until memory is available. The final argument is a *k_timeout_t* timeout value indicating how long the thread may sleep before returning, or else one of the constant timeout values *K_NO_WAIT* or *K_FOREVER*.

Releasing Memory Memory allocated with *k_heap_alloc()* must be released using *k_heap_free()*. Similar to standard C `free()`, the pointer provided must be either a `NULL` value or a pointer previously returned by *k_heap_alloc()* for the same heap. Freeing a `NULL` value is defined to have no effect.

Low Level Heap Allocator

The underlying implementation of the *k_heap* abstraction is provided a data structure named `sys_heap`. This implements exactly the same allocation semantics, but provides no kernel synchronization tools. It is available for applications that want to manage their own blocks of memory in contexts (for example, userspace) where synchronization is unavailable or more complicated. Unlike `k_heap`, all calls to any `sys_heap` functions on a single heap must be serialized by the caller. Simultaneous use from separate threads is disallowed.

Implementation Internally, the `sys_heap` memory block is partitioned into "chunks" of 8 bytes. All allocations are made out of a contiguous region of chunks. The first chunk of every allocation or unused block is prefixed by a chunk header that stores the length of the chunk, the length of the next lower ("left") chunk in physical memory, a bit indicating whether the chunk is in use, and chunk-indexed link pointers to the previous and next chunk in a "free list" to which unused chunks are added.

The heap code takes reasonable care to avoid fragmentation. Free block lists are stored in "buckets" by their size, each bucket storing blocks within one power of two (i.e. a bucket for blocks of 3-4 chunks, another for 5-8, 9-16, etc...) this allows new allocations to be made from the smallest/most-fragmented blocks available. Also, as allocations are freed and added to the heap, they are automatically combined with adjacent free blocks to prevent fragmentation.

All metadata is stored at the beginning of the contiguous block of heap memory, including the variable-length list of bucket list heads (which depend on heap size). The only external memory required is the `sys_heap` structure itself.

The `sys_heap` functions are unsynchronized. Care must be taken by any users to prevent concurrent access. Only one context may be inside one of the API functions at a time.

The heap code takes care to present high performance and reliable latency. All `sys_heap` API functions are guaranteed to complete within constant time. On typical architectures, they will all complete within 1-200 cycles. One complexity is that the search of the minimum bucket size for an allocation (the set of free blocks that "might fit") has a compile-time upper bound of iterations to prevent unbounded list searches, at the expense of some fragmentation resistance. This `CONFIG_SYS_HEAP_ALLOC_LOOPS` value may be chosen by the user at build time, and defaults to a value of 3.

Multi-Heap Wrapper Utility

The sys_heap utility requires that all managed memory be in a single contiguous block. It is common for complicated microcontroller applications to have more complicated memory setups that they still want to manage dynamically as a "heap". For example, the memory might exist as separate discontiguous regions, different areas may have different cache, performance or power behavior, peripheral devices may only be able to perform DMA to certain regions, etc...

For those situations, Zephyr provides a sys_multi_heap utility. Effectively this is a simple wrapper around a set of one or more sys_heap objects. It should be initialized after its child heaps via *sys_multi_heap_init()*, after which each heap can be added to the managed set via *sys_multi_heap_add_heap()*. No destruction utility is provided; just as for sys_heap, applications that want to destroy a multi heap should simply ensure all allocated blocks are freed (or at least will never be used again) and repurpose the underlying memory for another usage.

It has a single pair of allocation entry points, *sys_multi_heap_alloc()* and *sys_multi_heap_aligned_alloc()*. These behave identically to the sys_heap functions with similar names, except that they also accept an opaque "configuration" parameter. This pointer is uninspected by the multi heap code itself; instead it is passed to a callback function provided at initialization time. This application-provided callback is responsible for doing the underlying allocation from one of the managed heaps, and may use the configuration parameter in any way it likes to make that decision.

When unused, a multi heap may be freed via *sys_multi_heap_free()*. The application does not need to pass a configuration parameter. Memory allocated from any of the managed sys_heap objects may be freed with in the same way.

System Heap

The *system heap* is a predefined memory allocator that allows threads to dynamically allocate memory from a common memory region in a malloc()-like manner.

Only a single system heap is defined. Unlike other heaps or memory pools, the system heap cannot be directly referenced using its memory address.

The size of the system heap is configurable to arbitrary sizes, subject to space availability.

A thread can dynamically allocate a chunk of heap memory by calling *k_malloc()*. The address of the allocated chunk is guaranteed to be aligned on a multiple of pointer sizes. If a suitable chunk of heap memory cannot be found NULL is returned.

When the thread is finished with a chunk of heap memory it can release the chunk back to the system heap by calling *k_free()*.

Defining the Heap Memory Pool The size of the heap memory pool is specified using the CONFIG_HEAP_MEM_POOL_SIZE configuration option.

By default, the heap memory pool size is zero bytes. This value instructs the kernel not to define the heap memory pool object. The maximum size is limited by the amount of available memory in the system. The project build will fail in the link stage if the size specified can not be supported.

In addition, each subsystem (board, driver, library, etc) can set a custom requirement by defining a Kconfig option with the prefix HEAP_MEM_POOL_ADD_SIZE_ (this value is in bytes). If multiple subsystems specify custom values, the sum of these will be used as the minimum requirement. If the application tries to set a value that's less than the minimum value, this will be ignored and the minimum value will be used instead.

To force a smaller than minimum value to be used, the application may enable the CONFIG_HEAP_MEM_POOL_IGNORE_MIN option. This can be useful when optimizing the heap size and the minimum requirement can be more accurately determined for a specific application.

Allocating Memory A chunk of heap memory is allocated by calling *k_malloc()*.

The following code allocates a 200 byte chunk of heap memory, then fills it with zeros. A warning is issued if a suitable chunk is not obtained.

```
char *mem_ptr;

mem_ptr = k_malloc(200);
if (mem_ptr != NULL)) {
    memset(mem_ptr, 0, 200);
    ...
} else {
    printf("Memory not allocated");
}
```

Releasing Memory A chunk of heap memory is released by calling *k_free()*.

The following code allocates a 75 byte chunk of memory, then releases it once it is no longer needed.

```
char *mem_ptr;

mem_ptr = k_malloc(75);
... /* use memory block */
k_free(mem_ptr);
```

Suggested Uses Use the heap memory pool to dynamically allocate memory in a `malloc()`-like manner.

Configuration Options Related configuration options:

- `CONFIG_HEAP_MEM_POOL_SIZE`

API Reference

group `heap_apis`

Defines

`K_HEAP_DEFINE`(name, bytes)

Define a static *k_heap*.

This macro defines and initializes a static memory region and *k_heap* of the requested size. After kernel start, &name can be used as if *k_heap_init()* had been called.

Note that this macro enforces a minimum size on the memory region to accommodate metadata requirements. Very small heaps will be padded to fit.

Parameters

- `name` – Symbol name for the struct *k_heap* object
- `bytes` – Size of memory region, in bytes

K_HEAP_DEFINE_NOCACHE(name, bytes)

Define a static *k_heap* in uncached memory.

This macro defines and initializes a static memory region and *k_heap* of the requested size in uncached memory. After kernel start, &name can be used as if *k_heap_init()* had been called.

Note that this macro enforces a minimum size on the memory region to accommodate metadata requirements. Very small heaps will be padded to fit.

Parameters

- **name** – Symbol name for the struct *k_heap* object
- **bytes** – Size of memory region, in bytes

Functions

void **k_heap_init**(struct *k_heap* *h, void *mem, size_t bytes)

Initialize a *k_heap*.

This constructs a synchronized *k_heap* object over a memory region specified by the user. Note that while any alignment and size can be passed as valid parameters, internal alignment restrictions inside the inner sys_heap mean that not all bytes may be usable as allocated memory.

Parameters

- **h** – Heap struct to initialize
- **mem** – Pointer to memory.
- **bytes** – Size of memory region, in bytes

void ***k_heap_aligned_alloc**(struct *k_heap* *h, size_t align, size_t bytes, *k_timeout_t* timeout)

Allocate aligned memory from a *k_heap*.

Behaves in all ways like *k_heap_alloc()*, except that the returned memory (if available) will have a starting address in memory which is a multiple of the specified power-of-two alignment value in bytes. The resulting memory can be returned to the heap using *k_heap_free()*.

Function properties (list may not be complete)

isr-ok

> **Note**
>
> *timeout* must be set to K_NO_WAIT if called from ISR.

> **Note**
>
> When CONFIG_MULTITHREADING=n any *timeout* is treated as K_NO_WAIT.

Parameters

- **h** – Heap from which to allocate
- **align** – Alignment in bytes, must be a power of two

- **bytes** – Number of bytes requested
- **timeout** – How long to wait, or K_NO_WAIT

Returns
Pointer to memory the caller can now use

void *k_heap_alloc(struct *k_heap* *h, size_t bytes, *k_timeout_t* timeout)

Allocate memory from a *k_heap*.

Allocates and returns a memory buffer from the memory region owned by the heap. If no memory is available immediately, the call will block for the specified timeout (constructed via the standard timeout API, or K_NO_WAIT or K_FOREVER) waiting for memory to be freed. If the allocation cannot be performed by the expiration of the timeout, NULL will be returned. Allocated memory is aligned on a multiple of pointer sizes.

Function properties (list may not be complete)
isr-ok

Note

timeout must be set to K_NO_WAIT if called from ISR.

Note

When CONFIG_MULTITHREADING=n any *timeout* is treated as K_NO_WAIT.

Parameters

- **h** – Heap from which to allocate
- **bytes** – Desired size of block to allocate
- **timeout** – How long to wait, or K_NO_WAIT

Returns
A pointer to valid heap memory, or NULL

void *k_heap_realloc(struct *k_heap* *h, void *ptr, size_t bytes, *k_timeout_t* timeout)

Reallocate memory from a *k_heap*.

Reallocates and returns a memory buffer from the memory region owned by the heap. If no memory is available immediately, the call will block for the specified timeout (constructed via the standard timeout API, or K_NO_WAIT or K_FOREVER) waiting for memory to be freed. If the allocation cannot be performed by the expiration of the timeout, NULL will be returned. Reallocated memory is aligned on a multiple of pointer sizes.

Function properties (list may not be complete)
isr-ok

Note

timeout must be set to K_NO_WAIT if called from ISR.

Note

When CONFIG_MULTITHREADING=n any *timeout* is treated as K_NO_WAIT.

Parameters

- **h** – Heap from which to allocate
- **ptr** – Original pointer returned from a previous allocation
- **bytes** – Desired size of block to allocate
- **timeout** – How long to wait, or K_NO_WAIT

Returns
Pointer to memory the caller can now use, or NULL

void **k_heap_free**(struct *k_heap* *h, void *mem)

Free memory allocated by *k_heap_alloc()*

Returns the specified memory block, which must have been returned from *k_heap_alloc()*, to the heap for use by other callers. Passing a NULL block is legal, and has no effect.

Parameters

- **h** – Heap to which to return the memory
- **mem** – A valid memory block, or NULL

void ***k_aligned_alloc**(size_t align, size_t size)

Allocate memory from the heap with a specified alignment.

This routine provides semantics similar to aligned_alloc(); memory is allocated from the heap with a specified alignment. However, one minor difference is that *k_aligned_alloc()* accepts any non-zero `size`, whereas aligned_alloc() only accepts a `size` that is an integral multiple of `align`.

Above, aligned_alloc() refers to: C11 standard (ISO/IEC 9899:2011): 7.22.3.1 The aligned_alloc function (p: 347-348)

Parameters

- **align** – Alignment of memory requested (in bytes).
- **size** – Amount of memory requested (in bytes).

Returns
Address of the allocated memory if successful; otherwise NULL.

void ***k_malloc**(size_t size)

Allocate memory from the heap.

This routine provides traditional malloc() semantics. Memory is allocated from the heap memory pool. Allocated memory is aligned on a multiple of pointer sizes.

Parameters

- **size** – Amount of memory requested (in bytes).

Returns
Address of the allocated memory if successful; otherwise NULL.

void k_free(void *ptr)

Free memory allocated from heap.

This routine provides traditional free() semantics. The memory being returned must have been allocated from the heap memory pool.

If *ptr* is NULL, no operation is performed.

Parameters

- ptr – Pointer to previously allocated memory.

void *k_calloc(size_t nmemb, size_t size)

Allocate memory from heap, array style.

This routine provides traditional calloc() semantics. Memory is allocated from the heap memory pool and zeroed.

Parameters

- nmemb – Number of elements in the requested array
- size – Size of each array element (in bytes).

Returns

Address of the allocated memory if successful; otherwise NULL.

void *k_realloc(void *ptr, size_t size)

Expand the size of an existing allocation.

Returns a pointer to a new memory region with the same contents, but a different allocated size. If the new allocation can be expanded in place, the pointer returned will be identical. Otherwise the data will be copies to a new block and the old one will be freed as per *sys_heap_free()*. If the specified size is smaller than the original, the block will be truncated in place and the remaining memory returned to the heap. If the allocation of a new block fails, then NULL will be returned and the old block will not be freed or modified.

Parameters

- ptr – Original pointer returned from a previous allocation
- size – Amount of memory requested (in bytes).

Returns

Pointer to memory the caller can now use, or NULL.

struct k_heap

#include <kernel.h>

group low_level_heap_allocator

Defines

sys_heap_realloc(heap, ptr, bytes)

Functions

void sys_heap_init(struct sys_heap *heap, void *mem, size_t bytes)

Initialize sys_heap.

Initializes a sys_heap struct to manage the specified memory.

Parameters

- `heap` – Heap to initialize
- `mem` – Untyped pointer to unused memory
- `bytes` – Size of region pointed to by *mem*

void *`sys_heap_alloc`(struct sys_heap *heap, size_t bytes)

Allocate memory from a sys_heap.

Returns a pointer to a block of unused memory in the heap. This memory will not otherwise be used until it is freed with *sys_heap_free()*. If no memory can be allocated, NULL will be returned. The allocated memory is guaranteed to have a starting address which is a multiple of sizeof(void *). If a bigger alignment is necessary then *sys_heap_aligned_alloc()* should be used instead.

Note

The sys_heap implementation is not internally synchronized. No two sys_heap functions should operate on the same heap at the same time. All locking must be provided by the user.

Parameters

- `heap` – Heap from which to allocate
- `bytes` – Number of bytes requested

Returns

Pointer to memory the caller can now use

void *`sys_heap_aligned_alloc`(struct sys_heap *heap, size_t align, size_t bytes)

Allocate aligned memory from a sys_heap.

Behaves in all ways like *sys_heap_alloc()*, except that the returned memory (if available) will have a starting address in memory which is a multiple of the specified power-of-two alignment value in bytes. With align=0 this behaves exactly like *sys_heap_alloc()*. The resulting memory can be returned to the heap using *sys_heap_free()*.

Parameters

- `heap` – Heap from which to allocate
- `align` – Alignment in bytes, must be a power of two
- `bytes` – Number of bytes requested

Returns

Pointer to memory the caller can now use

void `sys_heap_free`(struct sys_heap *heap, void *mem)

Free memory into a sys_heap.

De-allocates a pointer to memory previously returned from sys_heap_alloc such that it can be used for other purposes. The caller must not use the memory region after entry to this function.

Note

The sys_heap implementation is not internally synchronized. No two sys_heap functions should operate on the same heap at the same time. All locking must be provided by the user.

Parameters

- `heap` – Heap to which to return the memory
- `mem` – A pointer previously returned from *sys_heap_alloc()*

void *`sys_heap_aligned_realloc`(struct sys_heap *heap, void *ptr, size_t align, size_t bytes)

Expand the size of an existing allocation.

Returns a pointer to a new memory region with the same contents, but a different allocated size. If the new allocation can be expanded in place, the pointer returned will be identical. Otherwise the data will be copies to a new block and the old one will be freed as per *sys_heap_free()*. If the specified size is smaller than the original, the block will be truncated in place and the remaining memory returned to the heap. If the allocation of a new block fails, then NULL will be returned and the old block will not be freed or modified.

Parameters

- `heap` – Heap from which to allocate
- `ptr` – Original pointer returned from a previous allocation
- `align` – Alignment in bytes, must be a power of two
- `bytes` – Number of bytes requested for the new block

Returns

Pointer to memory the caller can now use, or NULL

size_t `sys_heap_usable_size`(struct sys_heap *heap, void *mem)

Return allocated memory size.

Returns the size, in bytes, of a block returned from a successful *sys_heap_alloc()* or sys_heap_alloc_aligned() call. The value returned is the size of the heap-managed memory, which may be larger than the number of bytes requested due to allocation granularity. The heap code is guaranteed to make no access to this region of memory until a subsequent *sys_heap_free()* on the same pointer.

Parameters

- `heap` – Heap containing the block
- `mem` – Pointer to memory allocated from this heap

Returns

Size in bytes of the memory region

bool `sys_heap_validate`(struct sys_heap *heap)

Validate heap integrity.

Validates the internal integrity of a sys_heap. Intended for unit test and validation code, though potentially useful as a user API for applications with complicated runtime reliability requirements. Note: this cannot catch every possible error, but if it returns true then the heap is in a consistent state and can correctly handle any *sys_heap_alloc()* request and free any live pointer returned from a previous allocation.

Parameters

- `heap` – Heap to validate

Returns
true, if the heap is valid, otherwise false

void **sys_heap_stress**(void *(*alloc_fn)(void *arg, size_t bytes), void (*free_fn)(void *arg, void *p), void *arg, size_t total_bytes, uint32_t op_count, void *scratch_mem, size_t scratch_bytes, int target_percent, struct z_heap_stress_result *result)

sys_heap stress test rig

Test rig for heap allocation validation. This will loop for *op_count* cycles, in each iteration making a random choice to allocate or free a pointer of randomized (power law) size based on heuristics designed to keep the heap in a state where it is near *target_percent* full. Allocation and free operations are provided by the caller as callbacks (i.e. this can in theory test any heap). Results, including counts of frees and successful/unsuccessful allocations, are returned via the *result* struct.

Parameters

- **alloc_fn** – Callback to perform an allocation. Passes back the *arg* parameter as a context handle.
- **free_fn** – Callback to perform a free of a pointer returned from *alloc*. Passes back the *arg* parameter as a context handle.
- **arg** – Context handle to pass back to the callbacks
- **total_bytes** – Size of the byte array the heap was initialized in
- **op_count** – How many iterations to test
- **scratch_mem** – A pointer to scratch memory to be used by the test. Should be about 1/2 the size of the heap for tests that need to stress fragmentation.
- **scratch_bytes** – Size of the memory pointed to by *scratch_mem*
- **target_percent** – Percentage fill value (1-100) to which the random allocation choices will seek. High values will result in significant allocation failures and a very fragmented heap.
- **result** – Struct into which to store test results.

void **sys_heap_print_info**(struct sys_heap *heap, bool dump_chunks)

Print heap internal structure information to the console.

Print information on the heap structure such as its size, chunk buckets, chunk list and some statistics for debugging purpose.

Parameters

- **heap** – Heap to print information about
- **dump_chunks** – True to print the entire heap chunk list

group **multi_heap_wrapper**

Typedefs

typedef void *(***sys_multi_heap_fn_t**)(struct *sys_multi_heap* *mheap, void *cfg, size_t align, size_t size)

Multi-heap choice function.

This is a user-provided functions whose responsibility is selecting a specific sys_heap backend based on the opaque cfg value, which is specified by the user as an argument

to *sys_multi_heap_alloc()*, and performing the allocation on behalf of the caller. The callback is free to choose any registered heap backend to perform the allocation, and may choose to pad the user-provided values as needed, and to use an aligned allocation where required by the specified configuration.

NULL may be returned, which will cause the allocation to fail and a NULL reported to the calling code.

Param mheap
Multi-heap structure.

Param cfg
An opaque user-provided value. It may be interpreted in any way by the application

Param align
Alignment of requested memory (or zero for no alignment)

Param size
The user-specified allocation size in bytes

Return
A pointer to the allocated memory

Functions

void **sys_multi_heap_init**(struct *sys_multi_heap* *heap, *sys_multi_heap_fn_t* choice_fn)

Initialize multi-heap.

Initialize a *sys_multi_heap* struct with the specified choice function. Note that individual heaps must be added later with sys_multi_heap_add_heap so that the heap bounds can be tracked by the multi heap code.

Note

In general a multiheap is likely to be instantiated semi-statically from system configuration (for example, via linker-provided bounds on available memory in different regions, or from devicetree definitions of hardware-provided addressable memory, etc...). The general expectation is that a soc- or board-level platform device will be initialized at system boot from these upstream configuration sources and not that an application will assemble a multi-heap on its own.

Parameters

- **heap** – A *sys_multi_heap* to initialize
- **choice_fn** – A sys_multi_heap_fn_t callback used to select heaps at allocation time

void **sys_multi_heap_add_heap**(struct *sys_multi_heap* *mheap, struct sys_heap *heap, void *user_data)

Add sys_heap to multi heap.

This adds a known sys_heap backend to an existing multi heap, allowing the multi heap internals to track the bounds of the heap and determine which heap (if any) from which a freed block was allocated.

Parameters

- **mheap** – A *sys_multi_heap* to which to add a heap
- **heap** – The heap to add

- **user_data** – pointer to any data for the heap

void ***sys_multi_heap_alloc**(struct *sys_multi_heap* *mheap, void *cfg, size_t bytes)

Allocate memory from multi heap.

Just as for *sys_heap_alloc()*, allocates a block of memory of the specified size in bytes. Takes an opaque configuration pointer passed to the multi heap choice function, which is used by integration code to choose a heap backend.

Parameters

- **mheap** – Multi heap pointer
- **cfg** – Opaque configuration parameter, as for sys_multi_heap_fn_t
- **bytes** – Requested size of the allocation, in bytes

Returns

A valid pointer to heap memory, or NULL if no memory is available

void ***sys_multi_heap_aligned_alloc**(struct *sys_multi_heap* *mheap, void *cfg, size_t align, size_t bytes)

Allocate aligned memory from multi heap.

Just as for *sys_multi_heap_alloc()*, allocates a block of memory of the specified size in bytes. Takes an additional parameter specifying a power of two alignment, in bytes.

Parameters

- **mheap** – Multi heap pointer
- **cfg** – Opaque configuration parameter, as for sys_multi_heap_fn_t
- **align** – Power of two alignment for the returned pointer, in bytes
- **bytes** – Requested size of the allocation, in bytes

Returns

A valid pointer to heap memory, or NULL if no memory is available

const struct *sys_multi_heap_rec* ***sys_multi_heap_get_heap**(const struct *sys_multi_heap* *mheap, void *addr)

Get a specific heap for provided address.

Finds a single system heap (with user_data) controlling the provided pointer

Parameters

- **mheap** – Multi heap pointer
- **addr** – address to be found, must be a pointer to a block allocated by sys_multi_heap_alloc

Returns

0 multi_heap_rec pointer to a structure to be filled with return data or NULL if the heap has not been found

void **sys_multi_heap_free**(struct *sys_multi_heap* *mheap, void *block)

Free memory allocated from multi heap.

Returns the specified block, which must be the return value of a previously successful *sys_multi_heap_alloc()* or *sys_multi_heap_aligned_alloc()* call, to the heap backend from which it was allocated.

Accepts NULL as a block parameter, which is specified to have no effect.

Parameters

- **mheap** – Multi heap pointer

- **block** – Block to free, must be a pointer to a block allocated by sys_multi_heap_alloc

struct **sys_multi_heap_rec**

#include <*multi_heap.h*>

struct **sys_multi_heap**

#include <*multi_heap.h*>

Heap listener

group **heap_listener_apis**

Defines

HEAP_ID_FROM_POINTER(heap_pointer)

Construct heap identifier from heap pointer.

Construct a heap identifier from a pointer to the heap object, such as sys_heap.

Parameters

- **heap_pointer** – Pointer to the heap object

HEAP_ID_LIBC

Libc heap identifier.

Identifier of the global libc heap.

HEAP_LISTENER_ALLOC_DEFINE(name, _heap_id, _alloc_cb)

Define heap event listener node for allocation event.

Sample usage:

```
void on_heap_alloc(uintptr_t heap_id, void *mem, size_t bytes)
{
  LOG_INF("Memory allocated at %p, size %ld", mem, bytes);
}

HEAP_LISTENER_ALLOC_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_alloc);
```

Parameters

- **name** – Name of the heap event listener object
- **_heap_id** – Identifier of the heap to be listened
- **_alloc_cb** – Function to be called for allocation event

HEAP_LISTENER_FREE_DEFINE(name, _heap_id, _free_cb)

Define heap event listener node for free event.

Sample usage:

```
void on_heap_free(uintptr_t heap_id, void *mem, size_t bytes)
{
  LOG_INF("Memory freed at %p, size %ld", mem, bytes);
}

HEAP_LISTENER_FREE_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_free);
```

Parameters

- **name** – Name of the heap event listener object
- **_heap_id** – Identifier of the heap to be listened
- **_free_cb** – Function to be called for free event

HEAP_LISTENER_RESIZE_DEFINE(name, _heap_id, _resize_cb)

Define heap event listener node for resize event.

Sample usage:

```
void on_heap_resized(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)
{
  LOG_INF("Libc heap end moved from %p to %p", old_heap_end, new_heap_end);
}

HEAP_LISTENER_RESIZE_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_resized);
```

Parameters

- **name** – Name of the heap event listener object
- **_heap_id** – Identifier of the heap to be listened
- **_resize_cb** – Function to be called when the listened heap is resized

Typedefs

typedef void (*heap_listener_resize_cb_t)(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)

Callback used when heap is resized.

> **Note**
>
> Minimal C library does not emit this event.

Param heap_id
Identifier of heap being resized

Param old_heap_end
Pointer to end of heap before resize

Param new_heap_end
Pointer to end of heap after resize

typedef void (*heap_listener_alloc_cb_t)(uintptr_t heap_id, void *mem, size_t bytes)

Callback used when there is heap allocation.

Note

Heaps managed by libraries outside of code in Zephyr main code repository may not emit this event.

Note

The number of bytes allocated may not match exactly to the request to the allocation function. Internal mechanism of the heap may allocate more than requested.

Param heap_id
Heap identifier

Param mem
Pointer to the allocated memory

Param bytes
Size of allocated memory

typedef void (*`heap_listener_free_cb_t`)(uintptr_t heap_id, void *mem, size_t bytes)

Callback used when memory is freed from heap.

Note

Heaps managed by libraries outside of code in Zephyr main code repository may not emit this event.

Note

The number of bytes freed may not match exactly to the request to the allocation function. Internal mechanism of the heap dictates how memory is allocated or freed.

Param heap_id
Heap identifier

Param mem
Pointer to the freed memory

Param bytes
Size of freed memory

Enums

enum `heap_event_types`

Values:

enumerator `HEAP_EVT_UNKNOWN` = 0

enumerator `HEAP_RESIZE`

enumerator HEAP_ALLOC

enumerator HEAP_FREE

enumerator HEAP_REALLOC

enumerator HEAP_MAX_EVENTS

Functions

void heap_listener_register(struct *heap_listener* *listener)

Register heap event listener.

Add the listener to the global list of heap listeners that can be notified by different heap implementations upon certain events related to the heap usage.

Parameters

- listener – Pointer to the *heap_listener* object

void heap_listener_unregister(struct *heap_listener* *listener)

Unregister heap event listener.

Remove the listener from the global list of heap listeners that can be notified by different heap implementations upon certain events related to the heap usage.

Parameters

- listener – Pointer to the *heap_listener* object

void heap_listener_notify_alloc(uintptr_t heap_id, void *mem, size_t bytes)

Notify listeners of heap allocation event.

Notify registered heap event listeners with matching heap identifier that an allocation has been done on heap

Parameters

- heap_id – Heap identifier
- mem – Pointer to the allocated memory
- bytes – Size of allocated memory

void heap_listener_notify_free(uintptr_t heap_id, void *mem, size_t bytes)

Notify listeners of heap free event.

Notify registered heap event listeners with matching heap identifier that memory is freed on heap

Parameters

- heap_id – Heap identifier
- mem – Pointer to the freed memory
- bytes – Size of freed memory

void heap_listener_notify_resize(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)

Notify listeners of heap resize event.

Notify registered heap event listeners with matching heap identifier that the heap has been resized.

Parameters

- `heap_id` – Heap identifier
- `old_heap_end` – Address of the heap end before the change
- `new_heap_end` – Address of the heap end after the change

struct `heap_listener`

#include <heap_listener.h>

Public Members

sys_snode_t `node`

Singly linked list node.

uintptr_t `heap_id`

Identifier of the heap whose events are listened.

It can be a heap pointer, if the heap is represented as an object, or 0 in the case of the global libc heap.

enum *heap_event_types* `event`

The heap event to be notified.

3.4.2 Shared Multi Heap

The shared multi-heap memory pool manager uses the multi-heap allocator to manage a set of reserved memory regions with different capabilities / attributes (cacheable, non-cacheable, etc...).

All the different regions can be added at run-time to the shared multi-heap pool providing an opaque "attribute" value (an integer or enum value) that can be used by drivers or applications to request memory with certain capabilities.

This framework is commonly used as follow:

1. At boot time some platform code initialize the shared multi-heap framework using *shared_multi_heap_pool_init()* and add the memory regions to the pool with *shared_multi_heap_add()*, possibly gathering the needed information for the regions from the DT.
2. Each memory region encoded in a *shared_multi_heap_region* structure. This structure is also carrying an opaque and user-defined integer value that is used to define the region capabilities (for example: cacheability, cpu affinity, etc...)

```
// Init the shared multi-heap pool
shared_multi_heap_pool_init()

// Fill the struct with the data for cacheable memory
struct shared_multi_heap_region cacheable_r0 = {
     .addr = addr_r0,
     .size = size_r0,
     .attr = SMH_REG_ATTR_CACHEABLE,
};

// Add the region to the pool
```

(continues on next page)

(continued from previous page)

```
shared_multi_heap_add(&cacheable_r0, NULL);

// Add another cacheable region
struct shared_multi_heap_region cacheable_r1 = {
     .addr = addr_r1,
     .size = size_r1,
     .attr = SMH_REG_ATTR_CACHEABLE,
};

shared_multi_heap_add(&cacheable_r0, NULL);

// Add a non-cacheable region
struct shared_multi_heap_region non_cacheable_r2 = {
     .addr = addr_r2,
     .size = size_r2,
     .attr = SMH_REG_ATTR_NON_CACHEABLE,
};

shared_multi_heap_add(&non_cacheable_r2, NULL);
```

3. When a driver or application needs some dynamic memory with a certain capability, it can use *shared_multi_heap_alloc()* (or the aligned version) to request the memory by using the opaque parameter to select the correct set of attributes for the needed memory. The framework will take care of selecting the correct heap (thus memory region) to carve memory from, based on the opaque parameter and the runtime state of the heaps (available memory, heap state, etc...)

```
// Allocate 4K from cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_CACHEABLE, 0x1000);

// Allocate 4K from non-cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_NON_CACHEABLE, 0x1000);
```

Adding new attributes

The API does not enforce any attributes, but at least it defines the two most common ones: *SMH_REG_ATTR_CACHEABLE* and *SMH_REG_ATTR_NON_CACHEABLE*.

group **shared_multi_heap**

Shared Multi-Heap (SMH) interface.

The shared multi-heap manager uses the multi-heap allocator to manage a set of memory regions with different capabilities / attributes (cacheable, non-cacheable, etc...).

All the different regions can be added at run-time to the shared multi-heap pool providing an opaque "attribute" value (an integer or enum value) that can be used by drivers or applications to request memory with certain capabilities.

This framework is commonly used as follow:

- At boot time some platform code initialize the shared multi-heap framework using *shared_multi_heap_pool_init* and add the memory regions to the pool with *shared_multi_heap_add*, possibly gathering the needed information for the regions from the DT.
- Each memory region encoded in a *shared_multi_heap_region* structure. This structure is also carrying an opaque and user-defined integer value that is used to define the region capabilities (for example: cacheability, cpu affinity, etc...)

- When a driver or application needs some dynamic memory with a certain capability, it can use *shared_multi_heap_alloc* (or the aligned version) to request the memory by using the opaque parameter to select the correct set of attributes for the needed memory. The framework will take care of selecting the correct heap (thus memory region) to carve memory from, based on the opaque parameter and the runtime state of the heaps (available memory, heap state, etc...)

Defines

`MAX_SHARED_MULTI_HEAP_ATTR`
Maximum number of standard attributes.

Enums

enum **shared_multi_heap_attr**
SMH region attributes enumeration type.

Enumeration type for some common memory region attributes.

Values:

enumerator `SMH_REG_ATTR_CACHEABLE`
cacheable

enumerator `SMH_REG_ATTR_NON_CACHEABLE`
non-cacheable

enumerator `SMH_REG_ATTR_NUM`
must be the last item

Functions

int **shared_multi_heap_pool_init**(void)
Init the pool.

This must be the first function to be called to initialize the shared multi-heap pool. All the individual heaps must be added later with *shared_multi_heap_add*.

> **Note**
> As for the generic multi-heap allocator the expectation is that this function will be called at soc- or board-level.

Return values

- `0` – on success.
- `-EALREADY` – when the pool was already inited.
- `other` – errno codes

void *shared_multi_heap_alloc(enum *shared_multi_heap_attr* attr, size_t bytes)

Allocate memory from the memory shared multi-heap pool.

Allocates a block of memory of the specified size in bytes and with a specified capability / attribute. The opaque attribute parameter is used by the backend to select the correct heap to allocate memory from.

Parameters

- `attr` – capability / attribute requested for the memory block.
- `bytes` – requested size of the allocation in bytes.

Return values

- `ptr` – a valid pointer to heap memory.
- `err` – NULL if no memory is available.

void *shared_multi_heap_aligned_alloc(enum *shared_multi_heap_attr* attr, size_t align, size_t bytes)

Allocate aligned memory from the memory shared multi-heap pool.

Allocates a block of memory of the specified size in bytes and with a specified capability / attribute. Takes an additional parameter specifying a power of two alignment in bytes.

Parameters

- `attr` – capability / attribute requested for the memory block.
- `align` – power of two alignment for the returned pointer, in bytes.
- `bytes` – requested size of the allocation in bytes.

Return values

- `ptr` – a valid pointer to heap memory.
- `err` – NULL if no memory is available.

void shared_multi_heap_free(void *block)

Free memory from the shared multi-heap pool.

Used to free the passed block of memory that must be the return value of a previously call to *shared_multi_heap_alloc* or *shared_multi_heap_aligned_alloc*.

Parameters

- `block` – block to free, must be a pointer to a block allocated by shared_multi_heap_alloc or shared_multi_heap_aligned_alloc.

int shared_multi_heap_add(struct *shared_multi_heap_region* *region, void *user_data)

Add an heap region to the shared multi-heap pool.

This adds a shared multi-heap region to the multi-heap pool.

Parameters

- `user_data` – pointer to any data for the heap.
- `region` – pointer to the memory region to be added.

Return values

- `0` – on success.
- `-EINVAL` – when the region attribute is out-of-bound.
- `-ENOMEM` – when there are no more heaps available.
- `other` – errno codes

struct **shared_multi_heap_region**

#include <shared_multi_heap.h> SMH region struct.

This struct is carrying information about the memory region to be added in the multi-heap pool.

Public Members

uint32_t **attr**

Memory heap attribute.

uintptr_t **addr**

Memory heap starting virtual address.

size_t **size**

Memory heap size in bytes.

3.4.3 Memory Slabs

A *memory slab* is a kernel object that allows memory blocks to be dynamically allocated from a designated memory region. All memory blocks in a memory slab have a single fixed size, allowing them to be allocated and released efficiently and avoiding memory fragmentation concerns.

- *Concepts*
  - *Internal Operation*
- *Implementation*
  - *Defining a Memory Slab*
  - *Allocating a Memory Block*
  - *Releasing a Memory Block*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts

Any number of memory slabs can be defined (limited only by available RAM). Each memory slab is referenced by its memory address.

A memory slab has the following key properties:

- The **block size** of each block, measured in bytes. It must be at least 4N bytes long, where N is greater than 0.
- The **number of blocks** available for allocation. It must be greater than zero.
- A **buffer** that provides the memory for the memory slab's blocks. It must be at least "block size" times "number of blocks" bytes long.

The memory slab's buffer must be aligned to an N-byte boundary, where N is a power of 2 larger than 2 (i.e. 4, 8, 16, ...). To ensure that all memory blocks in the buffer are similarly aligned to this boundary, the block size must also be a multiple of N.

A memory slab must be initialized before it can be used. This marks all of its blocks as unused.

A thread that needs to use a memory block simply allocates it from a memory slab. When the thread finishes with a memory block, it must release the block back to the memory slab so the block can be reused.

If all the blocks are currently in use, a thread can optionally wait for one to become available. Any number of threads may wait on an empty memory slab simultaneously; when a memory block becomes available, it is given to the highest-priority thread that has waited the longest.

Unlike a heap, more than one memory slab can be defined, if needed. This allows for a memory slab with smaller blocks and others with larger-sized blocks. Alternatively, a memory pool object may be used.

Internal Operation A memory slab's buffer is an array of fixed-size blocks, with no wasted space between the blocks.

The memory slab keeps track of unallocated blocks using a linked list; the first 4 bytes of each unused block provide the necessary linkage.

Implementation

Defining a Memory Slab A memory slab is defined using a variable of type `k_mem_slab`. It must then be initialized by calling *k_mem_slab_init()*.

The following code defines and initializes a memory slab that has 6 blocks that are 400 bytes long, each of which is aligned to a 4-byte boundary.

```
struct k_mem_slab my_slab;
char __aligned(4) my_slab_buffer[6 * 400];

k_mem_slab_init(&my_slab, my_slab_buffer, 400, 6);
```

Alternatively, a memory slab can be defined and initialized at compile time by calling *K_MEM_SLAB_DEFINE*.

The following code has the same effect as the code segment above. Observe that the macro defines both the memory slab and its buffer.

```
K_MEM_SLAB_DEFINE(my_slab, 400, 6, 4);
```

Similarly, you can define a memory slab in private scope:

```
K_MEM_SLAB_DEFINE_STATIC(my_slab, 400, 6, 4);
```

Allocating a Memory Block A memory block is allocated by calling *k_mem_slab_alloc()*.

The following code builds on the example above, and waits up to 100 milliseconds for a memory block to become available, then fills it with zeroes. A warning is printed if a suitable block is not obtained.

```
char *block_ptr;

if (k_mem_slab_alloc(&my_slab, (void **)&block_ptr, K_MSEC(100)) == 0) {
    memset(block_ptr, 0, 400);
    ...
```

(continues on next page)

(continued from previous page)

```
} else {
    printf("Memory allocation time-out");
}
```

Releasing a Memory Block A memory block is released by calling *k_mem_slab_free()*.

The following code builds on the example above, and allocates a memory block, then releases it once it is no longer needed.

```
char *block_ptr;

k_mem_slab_alloc(&my_slab, (void **)&block_ptr, K_FOREVER);
... /* use memory block pointed at by block_ptr */
k_mem_slab_free(&my_slab, (void *)block_ptr);
```

Suggested Uses

Use a memory slab to allocate and free memory in fixed-size blocks.

Use memory slab blocks when sending large amounts of data from one thread to another, to avoid unnecessary copying of the data.

Configuration Options

- CONFIG_MEM_SLAB_TRACE_MAX_UTILIZATION

API Reference

group **mem_slab_apis**

Defines

K_MEM_SLAB_DEFINE(name, slab_block_size, slab_num_blocks, slab_align)

Statically define and initialize a memory slab in a public (non-static) scope.

The memory slab's buffer contains *slab_num_blocks* memory blocks that are *slab_block_size* bytes long. The buffer is aligned to a *slab_align* -byte boundary. To ensure that each memory block is similarly aligned to this boundary, *slab_block_size* must also be a multiple of *slab_align*.

The memory slab can be accessed outside the module where it is defined using:

```
extern struct k_mem_slab <name>;
```

Note

This macro cannot be used together with a static keyword. If such a use-case is desired, use *K_MEM_SLAB_DEFINE_STATIC* instead.

Parameters

- `name` – Name of the memory slab.
- `slab_block_size` – Size of each memory block (in bytes).
- `slab_num_blocks` – Number memory blocks.
- `slab_align` – Alignment of the memory slab's buffer (power of 2).

`K_MEM_SLAB_DEFINE_STATIC`(name, slab_block_size, slab_num_blocks, slab_align)

Statically define and initialize a memory slab in a private (static) scope.

The memory slab's buffer contains *slab_num_blocks* memory blocks that are *slab_block_size* bytes long. The buffer is aligned to a *slab_align* -byte boundary. To ensure that each memory block is similarly aligned to this boundary, *slab_block_size* must also be a multiple of *slab_align*.

Parameters

- `name` – Name of the memory slab.
- `slab_block_size` – Size of each memory block (in bytes).
- `slab_num_blocks` – Number memory blocks.
- `slab_align` – Alignment of the memory slab's buffer (power of 2).

Functions

int `k_mem_slab_init`(struct k_mem_slab *slab, void *buffer, size_t block_size, uint32_t num_blocks)

Initialize a memory slab.

Initializes a memory slab, prior to its first use.

The memory slab's buffer contains *slab_num_blocks* memory blocks that are *slab_block_size* bytes long. The buffer must be aligned to an N-byte boundary matching a word boundary, where N is a power of 2 (i.e. 4 on 32-bit systems, 8, 16, ...). To ensure that each memory block is similarly aligned to this boundary, *slab_block_size* must also be a multiple of N.

Parameters

- `slab` – Address of the memory slab.
- `buffer` – Pointer to buffer used for the memory blocks.
- `block_size` – Size of each memory block (in bytes).
- `num_blocks` – Number of memory blocks.

Return values

- `0` – on success
- `-EINVAL` – invalid data supplied

int `k_mem_slab_alloc`(struct k_mem_slab *slab, void **mem, *k_timeout_t* timeout)

Allocate memory from a memory slab.

This routine allocates a memory block from a memory slab.

Function properties (list may not be complete)

isr-ok

> **Note**
>
> *timeout* must be set to K_NO_WAIT if called from ISR.

> **Note**
>
> When CONFIG_MULTITHREADING=n any *timeout* is treated as K_NO_WAIT.

Parameters

- `slab` – Address of the memory slab.
- `mem` – Pointer to block address area.
- `timeout` – Waiting period to wait for operation to complete. Use K_NO_WAIT to return without waiting, or K_FOREVER to wait as long as necessary.

Return values

- `0` – Memory allocated. The block address area pointed at by *mem* is set to the starting address of the memory block.
- `-ENOMEM` – Returned without waiting.
- `-EAGAIN` – Waiting period timed out.
- `-EINVAL` – Invalid data supplied

void **k_mem_slab_free**(struct k_mem_slab *slab, void *mem)

Free memory allocated from a memory slab.

This routine releases a previously allocated memory block back to its associated memory slab.

Parameters

- `slab` – Address of the memory slab.
- `mem` – Pointer to the memory block (as returned by *k_mem_slab_alloc()*).

static inline uint32_t **k_mem_slab_num_used_get**(struct k_mem_slab *slab)

Get the number of used blocks in a memory slab.

This routine gets the number of memory blocks that are currently allocated in *slab*.

Parameters

- `slab` – Address of the memory slab.

Returns

Number of allocated memory blocks.

static inline uint32_t **k_mem_slab_max_used_get**(struct k_mem_slab *slab)

Get the number of maximum used blocks so far in a memory slab.

This routine gets the maximum number of memory blocks that were allocated in *slab*.

Parameters

- `slab` – Address of the memory slab.

Returns

Maximum number of allocated memory blocks.

static inline uint32_t **k_mem_slab_num_free_get**(struct k_mem_slab *slab)

Get the number of unused blocks in a memory slab.

This routine gets the number of memory blocks that are currently unallocated in *slab*.

Parameters

- **slab** – Address of the memory slab.

Returns

Number of unallocated memory blocks.

int **k_mem_slab_runtime_stats_get**(struct k_mem_slab *slab, struct sys_memory_stats *stats)

Get the memory stats for a memory slab.

This routine gets the runtime memory usage stats for the slab *slab*.

Parameters

- **slab** – Address of the memory slab
- **stats** – Pointer to memory into which to copy memory usage statistics

Return values

- **0** – Success
- **-EINVAL** – Any parameter points to NULL

int **k_mem_slab_runtime_stats_reset_max**(struct k_mem_slab *slab)

Reset the maximum memory usage for a slab.

This routine resets the maximum memory usage for the slab *slab* to its current usage.

Parameters

- **slab** – Address of the memory slab

Return values

- **0** – Success
- **-EINVAL** – Memory slab is NULL

3.4.4 Memory Blocks Allocator

The Memory Blocks Allocator allows memory blocks to be dynamically allocated from a designated memory region, where:

- All memory blocks have a single fixed size.
- Multiple blocks can be allocated or freed at the same time.
- A group of blocks allocated together may not be contiguous. This is useful for operations such as scatter-gather DMA transfers.
- Bookkeeping of allocated blocks is done outside of the associated buffer (unlike memory slab). This allows the buffer to reside in memory regions where these can be powered down to conserve energy.

  - *Allocating Memory Blocks*
  - *Releasing a Memory Block*
  - *Using Multi Memory Blocks Allocator Group*
- *API Reference*

Concepts

Any number of Memory Blocks Allocator can be defined (limited only by available RAM). Each allocator is referenced by its memory address.

A memory blocks allocator has the following key properties:

- The **block size** of each block, measured in bytes. It must be at least 4N bytes long, where N is greater than 0.
- The **number of blocks** available for allocation. It must be greater than zero.
- A **buffer** that provides the memory for the memory slab's blocks. It must be at least "block size" times "number of blocks" bytes long.
- A **blocks bitmap** to keep track of which block has been allocated.

The buffer must be aligned to an N-byte boundary, where N is a power of 2 larger than 2 (i.e. 4, 8, 16, ...). To ensure that all memory blocks in the buffer are similarly aligned to this boundary, the block size must also be a multiple of N.

Due to the use of internal bookkeeping structures and their creation, each memory blocks allocator must be declared and defined at compile time.

Internal Operation Each buffer associated with an allocator is an array of fixed-size blocks, with no wasted space between the blocks.

The memory blocks allocator keeps track of unallocated blocks using a bitmap.

Memory Blocks Allocator

Internally, the memory blocks allocator uses a bitmap to keep track of which blocks have been allocated. Each allocator, utilizing the `sys_bitarray` interface, gets memory blocks one by one from the backing buffer up to the requested number of blocks. All the metadata about an allocator is stored outside of the backing buffer. This allows the memory region of the backing buffer to be powered down to conserve energy, as the allocator code never touches the content of the buffer.

Multi Memory Blocks Allocator Group

The Multi Memory Blocks Allocator Group utility functions provide a convenient to manage a group of allocators. A custom allocator choosing function is used to choose which allocator to use among this group.

An allocator group should be initialized at runtime via *sys_multi_mem_blocks_init()*. Each allocator can then be added via *sys_multi_mem_blocks_add_allocator()*.

To allocate memory blocks from group, *sys_multi_mem_blocks_alloc()* is called with an opaque "configuration" parameter. This parameter is passed directly to the allocator choosing function so that an appropriate allocator can be chosen. After an allocator is chosen, memory blocks are allocated via *sys_mem_blocks_alloc()*.

Allocated memory blocks can be freed via *sys_multi_mem_blocks_free()*. The caller does not need to pass a configuration parameter. The allocator code matches the passed in memory addresses to find the correct allocator and then memory blocks are freed via *sys_mem_blocks_free()*.

Usage

Defining a Memory Blocks Allocator A memory blocks allocator is defined using a variable of type *sys_mem_blocks_t*. It needs to be defined and initialized at compile time by calling *SYS_MEM_BLOCKS_DEFINE*.

The following code defines and initializes a memory blocks allocator which has 4 blocks that are 64 bytes long, each of which is aligned to a 4-byte boundary:

```
SYS_MEM_BLOCKS_DEFINE(allocator, 64, 4, 4);
```

Similarly, you can define a memory blocks allocator in private scope:

```
SYS_MEM_BLOCKS_DEFINE_STATIC(static_allocator, 64, 4, 4);
```

A pre-defined buffer can also be provided to the allocator where the buffer can be placed separately. Note that the alignment of the buffer needs to be done at its definition.

```
uint8_t __aligned(4) backing_buffer[64 * 4];
SYS_MEM_BLOCKS_DEFINE_WITH_EXT_BUF(allocator, 64, 4, backing_buffer);
```

Allocating Memory Blocks Memory blocks can be allocated by calling *sys_mem_blocks_alloc()*.

```
int ret;
uintptr_t blocks[2];

ret = sys_mem_blocks_alloc(allocator, 2, blocks);
```

If `ret == 0`, the array `blocks` will contain an array of memory addresses pointing to the allocated blocks.

Releasing a Memory Block Memory blocks are released by calling *sys_mem_blocks_free()*.

The following code builds on the example above which allocates 2 memory blocks, then releases them once they are no longer needed.

```
int ret;
uintptr_t blocks[2];

ret = sys_mem_blocks_alloc(allocator, 2, blocks);
... /* perform some operations on the allocated memory blocks */
ret = sys_mem_blocks_free(allocator, 2, blocks);
```

Using Multi Memory Blocks Allocator Group The following code demonstrates how to initialize an allocator group:

```
sys_mem_blocks_t *choice_fn(struct sys_multi_mem_blocks *group, void *cfg)
{
    ...
}

SYS_MEM_BLOCKS_DEFINE(allocator0, 64, 4, 4);
SYS_MEM_BLOCKS_DEFINE(allocator1, 64, 4, 4);

static sys_multi_mem_blocks_t alloc_group;

sys_multi_mem_blocks_init(&alloc_group, choice_fn);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator0);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator1);
```

To allocate and free memory blocks from the group:

```
int ret;
uintptr_t blocks[1];
size_t blk_size;

ret = sys_multi_mem_blocks_alloc(&alloc_group, UINT_TO_POINTER(0),
                                 1, blocks, &blk_size);

ret = sys_multi_mem_blocks_free(&alloc_group, 1, blocks);
```

API Reference

group `mem_blocks_apis`

Defines

`SYS_MEM_BLOCKS_DEFINE`(name, blk_sz, num_blks, buf_align)

Create a memory block object with a new backing buffer.

Parameters

- `name` – Name of the memory block object.
- `blk_sz` – Size of each memory block (in bytes).
- `num_blks` – Total number of memory blocks.
- `buf_align` – Alignment of the memory block buffer (power of 2).

`SYS_MEM_BLOCKS_DEFINE_STATIC`(name, blk_sz, num_blks, buf_align)

Create a static memory block object with a new backing buffer.

Parameters

- `name` – Name of the memory block object.
- `blk_sz` – Size of each memory block (in bytes).
- `num_blks` – Total number of memory blocks.
- `buf_align` – Alignment of the memory block buffer (power of 2).

SYS_MEM_BLOCKS_DEFINE_WITH_EXT_BUF(name, blk_sz, num_blks, buf)

Create a memory block object with a providing backing buffer.

Parameters

- **name** – Name of the memory block object.
- **blk_sz** – Size of each memory block (in bytes).
- **num_blks** – Total number of memory blocks.
- **buf** – Backing buffer of type uint8_t.

SYS_MEM_BLOCKS_DEFINE_STATIC_WITH_EXT_BUF(name, blk_sz, num_blks, buf)

Create a static memory block object with a providing backing buffer.

Parameters

- **name** – Name of the memory block object.
- **blk_sz** – Size of each memory block (in bytes).
- **num_blks** – Total number of memory blocks.
- **buf** – Backing buffer of type uint8_t.

Typedefs

typedef struct sys_mem_blocks **sys_mem_blocks_t**

Memory Blocks Allocator.

typedef struct sys_multi_mem_blocks **sys_multi_mem_blocks_t**

Multi Memory Blocks Allocator.

typedef *sys_mem_blocks_t* *(***sys_multi_mem_blocks_choice_fn_t**)(struct sys_multi_mem_blocks *group, void *cfg)

Multi memory blocks allocator choice function.

This is a user-provided functions whose responsibility is selecting a specific memory blocks allocator based on the opaque cfg value, which is specified by the user as an argument to *sys_multi_mem_blocks_alloc()*. The callback returns a pointer to the chosen allocator where the allocation is performed.

NULL may be returned, which will cause the allocation to fail and a -EINVAL reported to the calling code.

Param group
Multi memory blocks allocator structure.

Param cfg
An opaque user-provided value. It may be interpreted in any way by the application.

Return
A pointer to the chosen allocator, or NULL if none is chosen.

Functions

int **sys_mem_blocks_alloc**(*sys_mem_blocks_t* *mem_block, size_t count, void **out_blocks)

Allocate multiple memory blocks.

Allocate multiple memory blocks, and place their pointers into the output array.

Parameters

- `mem_block` – **[in]** Pointer to memory block object.
- `count` – **[in]** Number of blocks to allocate.
- `out_blocks` – **[out]** Output array to be populated by pointers to the memory blocks. It must have at least `count` elements.

Return values

- `0` – Successful
- `-EINVAL` – Invalid argument supplied.
- `-ENOMEM` – Not enough blocks for allocation.

int **sys_mem_blocks_alloc_contiguous**(*sys_mem_blocks_t* *mem_block, size_t count, void **out_block)

Allocate a contiguous set of memory blocks.

Allocate multiple memory blocks, and place their pointers into the output array.

Parameters

- `mem_block` – **[in]** Pointer to memory block object.
- `count` – **[in]** Number of blocks to allocate.
- `out_block` – **[out]** Output pointer to the start of the allocated block set

Return values

- `0` – Successful
- `-EINVAL` – Invalid argument supplied.
- `-ENOMEM` – Not enough contiguous blocks for allocation.

int **sys_mem_blocks_get**(*sys_mem_blocks_t* *mem_block, void *in_block, size_t count)

Force allocation of a specified blocks in a memory block object.

Allocate a specified blocks in a memory block object. Note: use caution when mixing sys_mem_blocks_get and sys_mem_blocks_alloc, allocation may take any of the free memory space

Parameters

- `mem_block` – **[in]** Pointer to memory block object.
- `in_block` – **[in]** Address of the first required block to allocate
- `count` – **[in]** Number of blocks to allocate.

Return values

- `0` – Successful
- `-EINVAL` – Invalid argument supplied.
- `-ENOMEM` – Some of blocks are taken and cannot be allocated

int **sys_mem_blocks_is_region_free**(*sys_mem_blocks_t* *mem_block, void *in_block, size_t count)

check if the region is free

Parameters

- `mem_block` – **[in]** Pointer to memory block object.
- `in_block` – **[in]** Address of the first block to check
- `count` – **[in]** Number of blocks to check.

Return values

- `1` – All memory blocks are free
- `0` – At least one of the memory blocks is taken

int `sys_mem_blocks_free`(*sys_mem_blocks_t* *mem_block, size_t count, void **in_blocks)

Free multiple memory blocks.

Free multiple memory blocks according to the array of memory block pointers.

Parameters

- `mem_block` – **[in]** Pointer to memory block object.
- `count` – **[in]** Number of blocks to free.
- `in_blocks` – **[in]** Input array of pointers to the memory blocks.

Return values

- `0` – Successful
- `-EINVAL` – Invalid argument supplied.
- `-EFAULT` – Invalid pointers supplied.

int `sys_mem_blocks_free_contiguous`(*sys_mem_blocks_t* *mem_block, void *block, size_t count)

Free contiguous multiple memory blocks.

Free contiguous multiple memory blocks

Parameters

- `mem_block` – **[in]** Pointer to memory block object.
- `block` – **[in]** Pointer to the first memory block
- `count` – **[in]** Number of blocks to free.

Return values

- `0` – Successful
- `-EINVAL` – Invalid argument supplied.
- `-EFAULT` – Invalid pointer supplied.

void `sys_multi_mem_blocks_init`(*sys_multi_mem_blocks_t* *group, *sys_multi_mem_blocks_choice_fn_t* choice_fn)

Initialize multi memory blocks allocator group.

Initialize a sys_multi_mem_block struct with the specified choice function. Note that individual allocator must be added later with sys_multi_mem_blocks_add_allocator.

Parameters

- `group` – Multi memory blocks allocator structure.
- `choice_fn` – A sys_multi_mem_blocks_choice_fn_t callback used to select the allocator to be used at allocation time

void **sys_multi_mem_blocks_add_allocator**(*sys_multi_mem_blocks_t* *group, *sys_mem_blocks_t* *alloc)

Add an allocator to an allocator group.

This adds a known allocator to an existing multi memory blocks allocator group.

Parameters

- **group** – Multi memory blocks allocator structure.
- **alloc** – Allocator to add

int **sys_multi_mem_blocks_alloc**(*sys_multi_mem_blocks_t* *group, void *cfg, size_t count, void **out_blocks, size_t *blk_size)

Allocate memory from multi memory blocks allocator group.

Just as for *sys_mem_blocks_alloc()*, allocates multiple blocks of memory. Takes an opaque configuration pointer passed to the choice function, which is used by integration code to choose an allocator.

Parameters

- **group** – **[in]** Multi memory blocks allocator structure.
- **cfg** – **[in]** Opaque configuration parameter, as for sys_multi_mem_blocks_choice_fn_t
- **count** – **[in]** Number of blocks to allocate
- **out_blocks** – **[out]** Output array to be populated by pointers to the memory blocks. It must have at least `count` elements.
- **blk_size** – **[out]** If not NULL, output the block size of the chosen allocator.

Return values

- **0** – Successful
- **-EINVAL** – Invalid argument supplied, or no allocator chosen.
- **-ENOMEM** – Not enough blocks for allocation.

int **sys_multi_mem_blocks_free**(*sys_multi_mem_blocks_t* *group, size_t count, void **in_blocks)

Free memory allocated from multi memory blocks allocator group.

Free previous allocated memory blocks from *sys_multi_mem_blocks_alloc()*.

Note that all blocks in `in_blocks` must be from the same allocator.

Parameters

- **group** – **[in]** Multi memory blocks allocator structure.
- **count** – **[in]** Number of blocks to free.
- **in_blocks** – **[in]** Input array of pointers to the memory blocks.

Return values

- **0** – Successful
- **-EINVAL** – Invalid argument supplied, or no allocator chosen.
- **-EFAULT** – Invalid pointer(s) supplied.

3.4.5 Demand Paging

Demand paging provides a mechanism where data is only brought into physical memory as required by current execution context. The physical memory is conceptually divided in page-sized page frames as regions to hold data.

- When the processor tries to access data and the data page exists in one of the page frames, the execution continues without any interruptions.
- When the processor tries to access the data page that does not exist in any page frames, a page fault occurs. The paging code then brings in the corresponding data page from backing store into physical memory if there is a free page frame. If there is no more free page frames, the eviction algorithm is invoked to select a data page to be paged out, thus freeing up a page frame for new data to be paged in. If this data page has been modified after it is first paged in, the data will be written back into the backing store. If no modifications is done or after written back into backing store, the data page is now considered paged out and the corresponding page frame is now free. The paging code then invokes the backing store to page in the data page corresponding to the location of the requested data. The backing store copies that data page into the free page frame. Now the data page is in physical memory and execution can continue.

There are functions where paging in and out can be invoked manually using *k_mem_page_in()* and *k_mem_page_out()*. *k_mem_page_in()* can be used to page in data pages in anticipation that they are required in the near future. This is used to minimize number of page faults as these data pages are already in physical memory, and thus minimizing latency. *k_mem_page_out()* can be used to page out data pages where they are not going to be accessed for a considerable amount of time. This frees up page frames so that the next page in can be executed faster as the paging code does not need to invoke the eviction algorithm.

Terminology

Data Page
A data page is a page-sized region of data. It may exist in a page frame, or be paged out to some backing store. Its location can always be looked up in the CPU's page tables (or equivalent) by virtual address. The data type will always be `void *` or in some cases `uint8_t *` when doing pointer arithmetic.

Page Frame
A page frame is a page-sized physical memory region in RAM. It is a container where a data page may be placed. It is always referred to by physical address. Zephyr has a convention of using `uintptr_t` for physical addresses. For every page frame, a `struct k_mem_page_frame` is instantiated to store metadata. Flags for each page frame:

- `K_MEM_PAGE_FRAME_FREE` indicates a page frame is unused and on the list of free page frames. When this flag is set, none of the other flags are meaningful and they must not be modified.
- `K_MEM_PAGE_FRAME_PINNED` indicates a page frame is pinned in memory and should never be paged out.
- `K_MEM_PAGE_FRAME_RESERVED` indicates a physical page reserved by hardware and should not be used at all.
- `K_MEM_PAGE_FRAME_MAPPED` is set when a physical page is mapped to virtual memory address.
- `K_MEM_PAGE_FRAME_BUSY` indicates a page frame is currently involved in a page-in/out operation.
- `K_MEM_PAGE_FRAME_BACKED` indicates a page frame has a clean copy in the backing store.

K_MEM_SCRATCH_PAGE
: The virtual address of a special page provided to the backing store to: * Copy a data page from k_MEM_SCRATCH_PAGE to the specified location; or, * Copy a data page from the provided location to K_MEM_SCRATCH_PAGE. This is used as an intermediate page for page in/out operations. This scratch needs to be mapped read/write for backing store code to access. However the data page itself may only be mapped as read-only in virtual address space. If this page is provided as-is to backing store, the data page must be re-mapped as read/write which has security implications as the data page is no longer read-only to other parts of the application.

Paging Statistics

Paging statistics can be obtained via various function calls when CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS is enabled:

- Overall statistics via *k_mem_paging_stats_get()*
- Per-thread statistics via *k_mem_paging_thread_stats_get()* if CONFIG_DEMAND_PAGING_THREAD_STATS is enabled
- Execution time histogram can be obtained when CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM is enabled, and CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS is defined. Note that the timing is highly dependent on the architecture, SoC or board. It is highly recommended that k_mem_paging_eviction_histogram_bounds[] and k_mem_paging_backing_store_histogram_bounds[] be defined for a particular application.
  - Execution time histogram of eviction algorithm via *k_mem_paging_histogram_eviction_get()*
  - Execution time histogram of backing store doing page-in via *k_mem_paging_histogram_backing_store_page_in_get()*
  - Execution time histogram of backing store doing page-out via *k_mem_paging_histogram_backing_store_page_out_get()*

Eviction Algorithm

The eviction algorithm is used to determine which data page and its corresponding page frame can be paged out to free up a page frame for the next page in operation. There are two functions which are called from the kernel paging code:

- *k_mem_paging_eviction_init()* is called to initialize the eviction algorithm. This is called at POST_KERNEL.
- *k_mem_paging_eviction_select()* is called to select a data page to evict. A function argument dirty is written to signal the caller whether the selected data page has been modified since it is first paged in. If the dirty bit is returned as set, the paging code signals to the backing store to write the data page back into storage (thus updating its content). The function returns a pointer to the page frame corresponding to the selected data page.

Currently, a NRU (Not-Recently-Used) eviction algorithm has been implemented as a sample. This is a very simple algorithm which ranks each data page on whether they have been accessed and modified. The selection is based on this ranking.

To implement a new eviction algorithm, the two functions mentioned above must be implemented.

Backing Store

Backing store is responsible for paging in/out data page between their corresponding page frames and storage. These are the functions which must be implemented:

- *k_mem_paging_backing_store_init()* is called to initialized the backing store at POST_KERNEL.
- *k_mem_paging_backing_store_location_get()* is called to reserve a backing store location so a data page can be paged out. This location token is passed to *k_mem_paging_backing_store_page_out()* to perform actual page out operation.
- *k_mem_paging_backing_store_location_free()* is called to free a backing store location (the location token) which can then be used for subsequent page out operation.
- *k_mem_paging_backing_store_page_in()* copies a data page from the backing store location associated with the provided location token to the page pointed by K_MEM_SCRATCH_PAGE.
- *k_mem_paging_backing_store_page_out()* copies a data page from K_MEM_SCRATCH_PAGE to the backing store location associated with the provided location token.
- *k_mem_paging_backing_store_page_finalize()* is invoked after *k_mem_paging_backing_store_page_in()* so that the page frame struct may be updated for internal accounting. This can be a no-op.

To implement a new backing store, the functions mentioned above must be implemented. *k_mem_paging_backing_store_page_finalize()* can be an empty function if so desired.

API Reference

group mem-demand-paging

Functions

int **k_mem_page_out**(void *addr, size_t size)

Evict a page-aligned virtual memory region to the backing store.

Useful if it is known that a memory region will not be used for some time. All the data pages within the specified region will be evicted to the backing store if they weren't already, with their associated page frames marked as available for mappings or page-ins.

None of the associated page frames mapped to the provided region should be pinned.

Note that there are no guarantees how long these pages will be evicted, they could take page faults immediately.

If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by ISRs as the backing store may be in-use.

Parameters

- **addr** – Base page-aligned virtual address
- **size** – Page-aligned data region size

Return values

- **0** – Success
- **-ENOMEM** – Insufficient space in backing store to satisfy request. The region may be partially paged out.

void **k_mem_page_in**(void *addr, size_t size)

Load a virtual data region into memory.

After the function completes, all the page frames associated with this function will be paged in. However, they are not guaranteed to stay there. This is useful if the region is known to be used soon.

If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by ISRs as the backing store may be in-use.

Parameters

- **addr** – Base page-aligned virtual address
- **size** – Page-aligned data region size

void **k_mem_pin**(void *addr, size_t size)

Pin an aligned virtual data region, paging in as necessary.

After the function completes, all the page frames associated with this region will be resident in memory and pinned such that they stay that way. This is a stronger version of z_mem_page_in().

If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by ISRs as the backing store may be in-use.

Parameters

- **addr** – Base page-aligned virtual address
- **size** – Page-aligned data region size

void **k_mem_unpin**(void *addr, size_t size)

Un-pin an aligned virtual data region.

After the function completes, all the page frames associated with this region will be no longer marked as pinned. This does not evict the region, follow this with z_mem_page_out() if you need that.

Parameters

- **addr** – Base page-aligned virtual address
- **size** – Page-aligned data region size

void **k_mem_paging_stats_get**(struct *k_mem_paging_stats_t* *stats)

Get the paging statistics since system startup.

This populates the paging statistics struct being passed in as argument.

Parameters

- **stats** – **[inout]** Paging statistics struct to be filled.

void **k_mem_paging_thread_stats_get**(struct *k_thread* *thread, struct *k_mem_paging_stats_t* *stats)

Get the paging statistics since system startup for a thread.

This populates the paging statistics struct being passed in as argument for a particular thread.

Parameters

- **thread** – **[in]** Thread
- **stats** – **[inout]** Paging statistics struct to be filled.

void **k_mem_paging_histogram_eviction_get**(struct *k_mem_paging_histogram_t* *hist)

Get the eviction timing histogram.

This populates the timing histogram struct being passed in as argument.

Parameters

- **hist** – **[inout]** Timing histogram struct to be filled.

void **k_mem_paging_histogram_backing_store_page_in_get**(struct *k_mem_paging_histogram_t* *hist)

Get the backing store page-in timing histogram.

This populates the timing histogram struct being passed in as argument.

Parameters

- **hist** – **[inout]** Timing histogram struct to be filled.

void **k_mem_paging_histogram_backing_store_page_out_get**(struct *k_mem_paging_histogram_t* *hist)

Get the backing store page-out timing histogram.

This populates the timing histogram struct being passed in as argument.

Parameters

- **hist** – **[inout]** Timing histogram struct to be filled.

struct **k_mem_paging_stats_t**

#include <demand_paging.h> Paging Statistics.

Public Members

unsigned long **cnt**

Number of page faults.

unsigned long **irq_locked**

Number of page faults with IRQ locked.

unsigned long **irq_unlocked**

Number of page faults with IRQ unlocked.

unsigned long **in_isr**

Number of page faults while in ISR.

unsigned long **clean**

Number of clean pages selected for eviction.

unsigned long **dirty**

Number of dirty pages selected for eviction.

struct **k_mem_paging_histogram_t**

#include <demand_paging.h> Paging Statistics Histograms.

Eviction Algorithm APIs

group `mem-demand-paging-eviction`

Eviction algorithm APIs.

Functions

void **k_mem_paging_eviction_add**(struct k_mem_page_frame *pf)

Submit a page frame for eviction candidate tracking.

The kernel will invoke this to tell the eviction algorithm the provided page frame may be considered as a potential eviction candidate.

This function will never be called before the initial *k_mem_paging_eviction_init()*.

This function is invoked with interrupts locked.

Parameters

- `pf` – **[in]** The page frame to add

void **k_mem_paging_eviction_remove**(struct k_mem_page_frame *pf)

Remove a page frame from potential eviction candidates.

The kernel will invoke this to tell the eviction algorithm the provided page frame may no longer be considered as a potential eviction candidate.

This function will only be called with page frames that were submitted using *k_mem_paging_eviction_add()* beforehand.

This function is invoked with interrupts locked.

Parameters

- `pf` – **[in]** The page frame to remove

void **k_mem_paging_eviction_accessed**(uintptr_t phys)

Process a page frame as being newly accessed.

The architecture-specific memory fault handler will invoke this to tell the eviction algorithm the provided physical address belongs to a page frame being accessed and such page frame should become unlikely to be considered as the next eviction candidate.

This function is invoked with interrupts locked.

Parameters

- `phys` – **[in]** The physical address being accessed

struct k_mem_page_frame ***k_mem_paging_eviction_select**(bool *dirty)

Select a page frame for eviction.

The kernel will invoke this to choose a page frame to evict if there are no free page frames. It is not guaranteed that the returned page frame will actually be evicted. If it is then the kernel will call *k_mem_paging_eviction_remove()* with it.

This function will never be called before the initial *k_mem_paging_eviction_init()*.

This function is invoked with interrupts locked.

Parameters

- `dirty` – **[out]** Whether the page to evict is dirty

Returns

The page frame to evict

void k_mem_paging_eviction_init(void)

Initialization function.

Called at POST_KERNEL to perform any necessary initialization tasks for the eviction algorithm. *k_mem_paging_eviction_select()* is guaranteed to never be called until this has returned, and this will only be called once.

Backing Store APIs

group mem-demand-paging-backing-store

Backing store APIs.

Functions

int k_mem_paging_backing_store_location_get(struct k_mem_page_frame *pf, uintptr_t *location, bool page_fault)

Reserve or fetch a storage location for a data page loaded into a page frame.

The returned location token must be unique to the mapped virtual address. This location will be used in the backing store to page out data page contents for later retrieval. The location value must be page-aligned.

This function may be called multiple times on the same data page. If its page frame has its K_MEM_PAGE_FRAME_BACKED bit set, it is expected to return the previous backing store location for the data page containing a cached clean copy. This clean copy may be updated on page-out, or used to discard clean pages without needing to write out their contents.

If the backing store is full, some other backing store location which caches a loaded data page may be selected, in which case its associated page frame will have the K_MEM_PAGE_FRAME_BACKED bit cleared (as it is no longer cached).

k_mem_page_frame_to_virt(pf) will indicate the virtual address the page is currently mapped to. Large, sparse backing stores which can contain the entire address space may simply generate location tokens purely as a function of that virtual address with no other management necessary.

This function distinguishes whether it was called on behalf of a page fault. A free backing store location must always be reserved in order for page faults to succeed. If the page_fault parameter is not set, this function should return -ENOMEM even if one location is available.

This function is invoked with interrupts locked.

Parameters

- pf – Virtual address to obtain a storage location
- location – **[out]** storage location token
- page_fault – Whether this request was for a page fault

Returns
0 Success

Returns
-ENOMEM Backing store is full

void k_mem_paging_backing_store_location_free(uintptr_t location)

Free a backing store location.

Any stored data may be discarded, and the location token associated with this address may be re-used for some other data page.

This function is invoked with interrupts locked.

Parameters

- `location` – Location token to free

void `k_mem_paging_backing_store_page_out`(uintptr_t location)

Copy a data page from K_MEM_SCRATCH_PAGE to the specified location.

Immediately before this is called, K_MEM_SCRATCH_PAGE will be mapped read-write to the intended source page frame for the calling context.

Calls to this and *k_mem_paging_backing_store_page_in()* will always be serialized, but interrupts may be enabled.

Parameters

- `location` – Location token for the data page, for later retrieval

void `k_mem_paging_backing_store_page_in`(uintptr_t location)

Copy a data page from the provided location to K_MEM_SCRATCH_PAGE.

Immediately before this is called, K_MEM_SCRATCH_PAGE will be mapped read-write to the intended destination page frame for the calling context.

Calls to this and *k_mem_paging_backing_store_page_out()* will always be serialized, but interrupts may be enabled.

Parameters

- `location` – Location token for the data page

void `k_mem_paging_backing_store_page_finalize`(struct k_mem_page_frame *pf, uintptr_t location)

Update internal accounting after a page-in.

This is invoked after *k_mem_paging_backing_store_page_in()* and interrupts have been* re-locked, making it safe to access the k_mem_page_frame data. The location value will be the same passed to *k_mem_paging_backing_store_page_in()*.

The primary use-case for this is to update custom fields for the backing store in the page frame, to reflect where the data should be evicted to if it is paged out again. This may be a no-op in some implementations.

If the backing store caches paged-in data pages, this is the appropriate time to set the K_MEM_PAGE_FRAME_BACKED bit. The kernel only skips paging out clean data pages if they are noted as clean in the page tables and the K_MEM_PAGE_FRAME_BACKED bit is set in their associated page frame.

Parameters

- `pf` – Page frame that was loaded in
- `location` – Location of where the loaded data page was retrieved

void `k_mem_paging_backing_store_init`(void)

Backing store initialization function.

The implementation may expect to receive page in/out calls as soon as this returns, but not before that. Called at POST_KERNEL.

This function is expected to do two things:

- Initialize any internal data structures and accounting for the backing store.
- If the backing store already contains all or some loaded kernel data pages at boot time, K_MEM_PAGE_FRAME_BACKED should be appropriately set for their associated page frames, and any internal accounting set up appropriately.

3.4.6 Virtual Memory

Virtual memory (VM) in Zephyr provides developers with the ability to fine tune access to memory. To utilize virtual memory, the platform must support Memory Management Unit (MMU) and it must be enabled in the build. Due to the target of Zephyr mainly being embedded systems, virtual memory support in Zephyr differs a bit from that in traditional operating systems:

Mapping of Kernel Image
Default is to do 1:1 mapping for the kernel image (including code and data) between physical and virtual memory address spaces, if demand paging is not enabled. Deviation from this requires careful manipulation of linker script.

Secondary Storage
Basic virtual memory support does not utilize secondary storage to extend usable memory. The maximum usable memory is the same as the physical memory.

- *Demand Paging* enables utilizing secondary storage as a backing store for virtual memory, thus allowing larger usable memory than the available physical memory. Note that demand paging needs to be explicitly enabled.
- Although the virtual memory space can be larger than physical memory space, without enabling demand paging, all virtually mapped memory must be backed by physical memory.

Kconfigs

Required These are the Kconfigs that need to be enabled or defined for kernel to support virtual memory.

- `CONFIG_MMU`: must be enabled for virtual memory support in kernel.
- `CONFIG_MMU_PAGE_SIZE`: size of a memory page. Default is 4KB.
- `CONFIG_KERNEL_VM_BASE`: base address of virtual address space.
- `CONFIG_KERNEL_VM_SIZE`: size of virtual address space. Default is 8MB.
- `CONFIG_KERNEL_VM_OFFSET`: kernel image starts at this offset from `CONFIG_KERNEL_VM_BASE`.

Optional

- `CONFIG_KERNEL_DIRECT_MAP`: permits 1:1 mappings between virtual and physical addresses, instead of kernel choosing addresses within the virtual address space. This is useful for mapping device MMIO regions for more precise access control.

Memory Map Overview

This is an overview of the memory map of the virtual memory address space. Note that the `Z_*` macros, which are used in code, may have different meanings depending on architecture and Kconfigs, which will be explained below.

```
+--------------+ <- K_MEM_VIRT_RAM_START
| Undefined VM | <- architecture specific reserved area
+--------------+ <- K_MEM_KERNEL_VIRT_START
| Mapping for  |
| main kernel  |
| image        |
|              |
|              |
+--------------+ <- K_MEM_VM_FREE_START
```

(continues on next page)

(continued from previous page)

```
|              |
| Unused,      |
| Available VM |
|              |
|..............| <- grows downward as more mappings are made
| Mapping      |
+--------------+
| Mapping      |
+--------------+
| ...          |
+--------------+
| Mapping      |
+--------------+ <- memory mappings start here
| Reserved     | <- special purpose virtual page(s) of size K_MEM_VM_RESERVED
+--------------+ <- K_MEM_VIRT_RAM_END
```

- `K_MEM_VIRT_RAM_START` is the beginning of the virtual memory address space. This needs to be page aligned. Currently, it is the same as `CONFIG_KERNEL_VM_BASE`.
- `K_MEM_VIRT_RAM_SIZE` is the size of the virtual memory address space. This needs to be page aligned. Currently, it is the same as `CONFIG_KERNEL_VM_SIZE`.
- `K_MEM_VIRT_RAM_END` is simply (`K_MEM_VIRT_RAM_START` + `K_MEM_VIRT_RAM_SIZE`).
- `K_MEM_KERNEL_VIRT_START` is the same as `z_mapped_start` specified in the linker script. This is the virtual address of the beginning of the kernel image at boot time.
- `K_MEM_KERNEL_VIRT_END` is the same as `z_mapped_end` specified in the linker script. This is the virtual address of the end of the kernel image at boot time.
- `K_MEM_VM_FREE_START` is the beginning of the virtual address space where addresses can be allocated for memory mapping. This depends on whether `CONFIG_ARCH_MAPS_ALL_RAM` is enabled.
  - If it is enabled, which means all physical memory are mapped in virtual memory address space, and it is the same as (`CONFIG_SRAM_BASE_ADDRESS` + `CONFIG_SRAM_SIZE`).
  - If it is disabled, `K_MEM_VM_FREE_START` is the same `K_MEM_KERNEL_VIRT_END` which is the end of the kernel image.
- `K_MEM_VM_RESERVED` is an area reserved to support kernel functions. For example, some addresses are reserved to support demand paging.

Virtual Memory Mappings

Setting up Mappings at Boot In general, most supported architectures set up the memory mappings at boot as following:

- `.text` section is read-only and executable. It is accessible in both kernel and user modes.
- `.rodata` section is read-only and non-executable. It is accessible in both kernel and user modes.
- Other kernel sections, such as `.data`, `.bss` and `.noinit`, are read-write and non-executable. They are only accessible in kernel mode.
  - Stacks for user mode threads are automatically granted read-write access to their corresponding user mode threads during thread creation.
  - Global variables, by default, are not accessible to user mode threads. Refer to *Memory Domains and Partitions* on how to use global variables in user mode threads, and on how to share data between user mode threads.

Caching modes for these mappings are architecture specific. They can be none, write-back, or write-through.

Note that SoCs have their own additional mappings required to boot where these mappings are defined under their own SoC configurations. These mappings usually include device MMIO regions needed to setup the hardware.

Mapping Anonymous Memory The unused physical memory can be mapped in virtual address space on demand. This is conceptually similar to memory allocation from heap, but these mappings must be aligned on page size and have finer access control.

- *k_mem_map()* can be used to map unused physical memory:
  - The requested size must be multiple of page size.
  - The address returned is inside the virtual address space between K_MEM_VM_FREE_START and K_MEM_VIRT_RAM_END.
  - The mapped region is not guaranteed to be physically contiguous in memory.
  - Guard pages immediately before and after the mapped virtual region are automatically allocated to catch access issue due to buffer underrun or overrun.
- The mapped region can be unmapped (i.e. freed) via *k_mem_unmap()*:
  - Caution must be exercised to give the pass the same region size to both *k_mem_map()* and *k_mem_unmap()*. The unmapping function does not check if it is a valid mapped region before unmapping.

API Reference

group kernel_memory_management

Kernel Memory Management.

Caching mode definitions.

These are mutually exclusive.

K_MEM_CACHE_NONE

No caching.

Most drivers want this.

K_MEM_CACHE_WT

Write-through caching.

Used by certain drivers.

K_MEM_CACHE_WB

Full write-back caching.

Any RAM mapped wants this.

K_MEM_CACHE_MASK

Reserved bits for cache modes in k_map() flags argument.

Region permission attributes.

Default is read-only, no user, no exec

K_MEM_PERM_RW
: Region will have read/write access (and not read-only)

K_MEM_PERM_EXEC
: Region will be executable (normally forbidden)

K_MEM_PERM_USER
: Region will be accessible to user mode (normally supervisor-only)

Region mapping behaviour attributes

K_MEM_DIRECT_MAP
: Region will be mapped to 1:1 virtual and physical address.

k_mem_map() control flags

K_MEM_MAP_UNINIT
: The mapped region is not guaranteed to be zeroed.

  This may improve performance. The associated page frames may contain indeterminate data, zeroes, or even sensitive information.

  This may not be used with K_MEM_PERM_USER as there are no circumstances where this is safe.

K_MEM_MAP_LOCK
: Region will be pinned in memory and never paged.

  Such memory is guaranteed to never produce a page fault due to page-outs or copy-on-write once the mapping call has returned. Physical page frames will be pre-fetched as necessary and pinned.

Functions

size_t **k_mem_free_get**(void)
: Return the amount of free memory available.

  The returned value will reflect how many free RAM page frames are available. If demand paging is enabled, it may still be possible to allocate more.

  The information reported by this function may go stale immediately if concurrent memory mappings or page-ins take place.

  Returns
  Free physical RAM, in bytes

static inline void *k_mem_map(size_t size, uint32_t flags)

Map anonymous memory into Zephyr's address space.

This function effectively increases the data space available to Zephyr. The kernel will choose a base virtual address and return it to the caller. The memory will have access permissions for all contexts set per the provided flags argument.

If user thread access control needs to be managed in any way, do not enable K_MEM_PERM_USER flags here; instead manage the region's permissions with memory domain APIs after the mapping has been established. Setting K_MEM_PERM_USER here will allow all user threads to access this memory which is usually undesirable.

Unless K_MEM_MAP_UNINIT is used, the returned memory will be zeroed.

The mapped region is not guaranteed to be physically contiguous in memory. Physically contiguous buffers should be allocated statically and pinned at build time.

Pages mapped in this way have write-back cache settings.

The returned virtual memory pointer will be page-aligned. The size parameter, and any base address for re-mapping purposes must be page- aligned.

Note that the allocation includes two guard pages immediately before and after the requested region. The total size of the allocation will be the requested size plus the size of these two guard pages.

Many K_MEM_MAP_* flags have been implemented to alter the behavior of this function, with details in the documentation for these flags.

Parameters

- `size` – Size of the memory mapping. This must be page-aligned.
- `flags` – K_MEM_PERM_*, K_MEM_MAP_* control flags.

Returns

The mapped memory location, or NULL if insufficient virtual address space, insufficient physical memory to establish the mapping, or insufficient memory for paging structures.

static inline void k_mem_unmap(void *addr, size_t size)

Un-map mapped memory.

This removes a memory mapping for the provided page-aligned region. Associated page frames will be free and the kernel may re-use the associated virtual address region. Any paged out data pages may be discarded.

Calling this function on a region which was not mapped to begin with is undefined behavior.

Parameters

- `addr` – Page-aligned memory region base virtual address
- `size` – Page-aligned memory region size

size_t k_mem_region_align(uintptr_t *aligned_addr, size_t *aligned_size, uintptr_t addr, size_t size, size_t align)

Given an arbitrary region, provide a aligned region that covers it.

The returned region will have both its base address and size aligned to the provided alignment value.

Parameters

- `aligned_addr` – **[out]** Aligned address
- `aligned_size` – **[out]** Aligned region size

- `addr` – **[in]** Region base address
- `size` – **[in]** Region size
- `align` – **[in]** What to align the address and size to

Return values
`offset` – between aligned_addr and addr

3.5 Data Structures

Zephyr provides a library of common general purpose data structures used within the kernel, but useful by application code in general. These include list and balanced tree structures for storing ordered data, and a ring buffer for managing "byte stream" data in a clean way.

Note that in general, the collections are implemented as "intrusive" data structures. The "node" data is the only struct used by the library code, and it does not store a pointer or other metadata to indicate what user data is "owned" by that node. Instead, the expectation is that the node will be itself embedded within a user-defined struct. Macros are provided to retrieve a user struct address from the embedded node pointer in a clean way. The purpose behind this design is to allow the collections to be used in contexts where dynamic allocation is disallowed (i.e. there is no need to allocate node objects because the memory is provided by the user).

Note also that these libraries are uniformly unsynchronized; access to them is not threadsafe by default. These are data structures, not synchronization primitives. The expectation is that any locking needed will be provided by the user.

3.5.1 Single-linked List

Zephyr provides a *sys_slist_t* type for storing simple singly-linked list data (i.e. data where each list element stores a pointer to the next element, but not the previous one). This supports constant-time access to the first (head) and last (tail) elements of the list, insertion before the head and after the tail of the list and constant time removal of the head. Removal of subsequent nodes requires access to the "previous" pointer and thus can only be performed in linear time by searching the list.

The *sys_slist_t* struct may be instantiated by the user in any accessible memory. It should be initialized with either *sys_slist_init()* or by static assignment from SYS_SLIST_STATIC_INIT before use. Its interior fields are opaque and should not be accessed by user code.

The end nodes of a list may be retrieved with *sys_slist_peek_head()* and *sys_slist_peek_tail()*, which will return NULL if the list is empty, otherwise a pointer to a *sys_snode_t* struct.

The *sys_snode_t* struct represents the data to be inserted. In general, it is expected to be allocated/controlled by the user, usually embedded within a struct which is to be added to the list. The container struct pointer may be retrieved from a list node using *SYS_SLIST_CONTAINER*, passing it the struct name of the containing struct and the field name of the node. Internally, the *sys_snode_t* struct contains only a next pointer, which may be accessed with *sys_slist_peek_next()*.

Lists may be modified by adding a single node at the head or tail with *sys_slist_prepend()* and *sys_slist_append()*. They may also have a node added to an interior point with *sys_slist_insert()*, which inserts a new node after an existing one. Similarly *sys_slist_remove()* will remove a node given a pointer to its predecessor. These operations are all constant time.

Convenience routines exist for more complicated modifications to a list. *sys_slist_merge_slist()* will append an entire list to an existing one. *sys_slist_append_list()* will append a bounded subset of an existing list in constant

time. And *sys_slist_find_and_remove()* will search a list (in linear time) for a given node and remove it if present.

Finally the slist implementation provides a set of "for each" macros that allows for iterating over a list in a natural way without needing to manually traverse the next pointers. *SYS_SLIST_FOR_EACH_NODE* will enumerate every node in a list given a local variable to store the node pointer. *SYS_SLIST_FOR_EACH_NODE_SAFE* behaves similarly, but has a more complicated implementation that requires an extra scratch variable for storage and allows the user to delete the iterated node during the iteration. Each of those macros also exists in a "container" variant (*SYS_SLIST_FOR_EACH_CONTAINER* and *SYS_SLIST_FOR_EACH_CONTAINER_SAFE*) which assigns a local variable of a type that matches the user's container struct and not the node struct, performing the required offsets internally. And *SYS_SLIST_ITERATE_FROM_NODE* exists to allow for enumerating a node and all its successors only, without inspecting the earlier part of the list.

Single-linked List Internals

The slist code is designed to be minimal and conventional. Internally, a *sys_slist_t* struct is nothing more than a pair of "head" and "tail" pointer fields. And a *sys_snode_t* stores only a single "next" pointer.

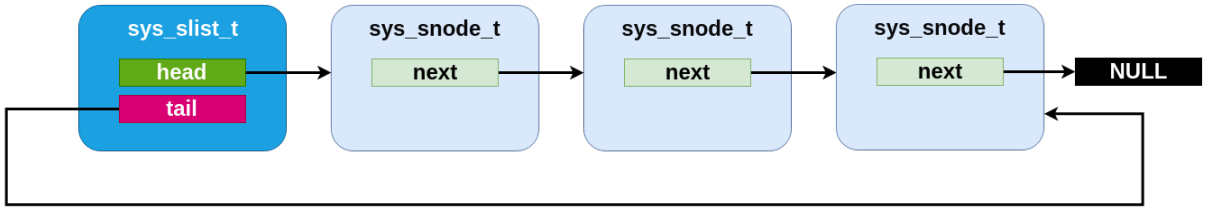

Fig. 4: An slist containing three elements.

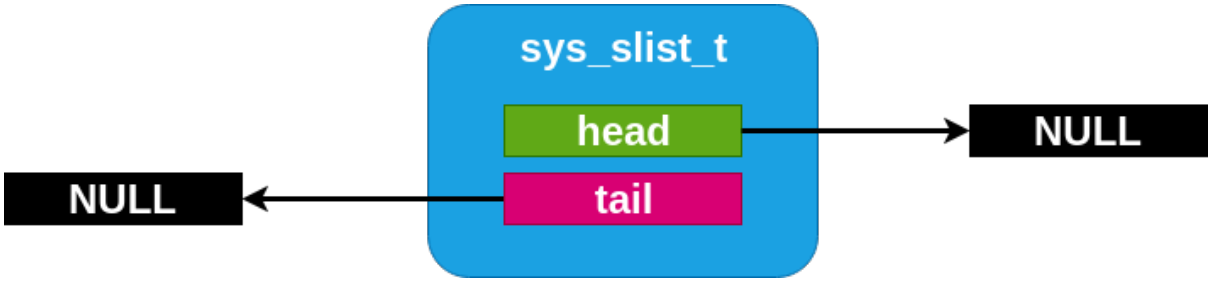

Fig. 5: An empty slist

The specific implementation of the list code, however, is done with an internal "Z_GENLIST" template API which allows for extracting those fields from arbitrary structures and emits an arbitrarily named set of functions. This allows for implementing more complicated single-linked list variants using the same basic primitives. The genlist implementor is responsible for a custom implementation of the primitive operations only: an "init" step for each struct, and a "get" and "set" primitives for each of head, tail and next pointers on their relevant structs. These inline functions are passed as parameters to the genlist macro expansion.

Only one such variant, sflist, exists in Zephyr at the moment.

Flagged List

The *sys_sflist_t* is implemented using the described genlist template API. With the exception of symbol naming ("sflist" instead of "slist") and the additional API described next, it operates in all ways identically to the slist API.

It adds the ability to associate exactly two bits of user defined "flags" with each list node. These can be accessed and modified with *sys_sfnode_flags_get()* and *sys_sfnode_flags_set()*. Internally, the flags are stored unioned with the bottom bits of the next pointer and incur no SRAM storage overhead when compared with the simpler slist code.

Single-linked List API Reference

group `single-linked-list_apis`

Single-linked list implementation.

Single-linked list implementation using inline macros/functions. This API is not thread safe, and thus if a list is used across threads, calls to functions must be protected with synchronization primitives.

Defines

`SYS_SLIST_FOR_EACH_NODE`(__sl, __sn)

Provide the primitive to iterate on a list Note: the loop is unsafe and thus __sn should not be removed.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_SLIST_FOR_EACH_NODE(l, n) {
    <user code>
}
```

This and other SYS_SLIST_*() macros are not thread safe.

Parameters

- **__sl** – A pointer on a sys_slist_t to iterate on
- **__sn** – A sys_snode_t pointer to peek each node of the list

`SYS_SLIST_ITERATE_FROM_NODE`(__sl, __sn)

Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and thus __sn should not be removed.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_SLIST_ITERATE_FROM_NODE(l, n) {
    <user code>
}
```

Like *SYS_SLIST_FOR_EACH_NODE()*, but __dn already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.

This and other SYS_SLIST_*() macros are not thread safe.

Parameters

- **__sl** – A pointer on a sys_slist_t to iterate on
- **__sn** – A sys_snode_t pointer to peek each node of the list it contains the starting node, or NULL to start from the head

`SYS_SLIST_FOR_EACH_NODE_SAFE`(__sl, __sn, __sns)

Provide the primitive to safely iterate on a list Note: __sn can be removed, it will not break the loop.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_SLIST_FOR_EACH_NODE_SAFE(l, n, s) {
    <user code>
}
```

This and other SYS_SLIST_*() macros are not thread safe.

Parameters

- **__sl** – A pointer on a sys_slist_t to iterate on
- **__sn** – A sys_snode_t pointer to peek each node of the list
- **__sns** – A sys_snode_t pointer for the loop to run safely

SYS_SLIST_CONTAINER(__ln, __cn, __n)

Provide the primitive to resolve the container of a list node Note: it is safe to use with NULL pointer nodes.

Parameters

- **__ln** – A pointer on a sys_node_t to get its container
- **__cn** – Container struct type pointer
- **__n** – The field name of sys_node_t within the container struct

SYS_SLIST_PEEK_HEAD_CONTAINER(__sl, __cn, __n)

Provide the primitive to peek container of the list head.

Parameters

- **__sl** – A pointer on a sys_slist_t to peek
- **__cn** – Container struct type pointer
- **__n** – The field name of sys_node_t within the container struct

SYS_SLIST_PEEK_TAIL_CONTAINER(__sl, __cn, __n)

Provide the primitive to peek container of the list tail.

Parameters

- **__sl** – A pointer on a sys_slist_t to peek
- **__cn** – Container struct type pointer
- **__n** – The field name of sys_node_t within the container struct

SYS_SLIST_PEEK_NEXT_CONTAINER(__cn, __n)

Provide the primitive to peek the next container.

Parameters

- **__cn** – Container struct type pointer
- **__n** – The field name of sys_node_t within the container struct

SYS_SLIST_FOR_EACH_CONTAINER(__sl, __cn, __n)

Provide the primitive to iterate on a list under a container Note: the loop is unsafe and thus __cn should not be detached.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_SLIST_FOR_EACH_CONTAINER(l, c, n) {
    <user code>
}
```

Parameters

- **__sl** – A pointer on a sys_slist_t to iterate on

- **__cn** – A pointer to peek each entry of the list
- **__n** – The field name of sys_node_t within the container struct

SYS_SLIST_FOR_EACH_CONTAINER_SAFE(__sl, __cn, __cns, __n)

Provide the primitive to safely iterate on a list under a container Note: __cn can be detached, it will not break the loop.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_SLIST_FOR_EACH_NODE_SAFE(l, c, cn, n) {
    <user code>
}
```

Parameters

- **__sl** – A pointer on a sys_slist_t to iterate on
- **__cn** – A pointer to peek each entry of the list
- **__cns** – A pointer for the loop to run safely
- **__n** – The field name of sys_node_t within the container struct

SYS_SLIST_STATIC_INIT(ptr_to_list)

Statically initialize a single-linked list.

Parameters

- **ptr_to_list** – A pointer on the list to initialize

Typedefs

typedef struct _snode **sys_snode_t**

Single-linked list node structure.

typedef struct _slist **sys_slist_t**

Single-linked list structure.

Functions

static inline void **sys_slist_init**(*sys_slist_t* *list)

Initialize a list.

Parameters

- **list** – A pointer on the list to initialize

static inline *sys_snode_t* ***sys_slist_peek_head**(*sys_slist_t* *list)

Peek the first node from the list.

Parameters

- **list** – A point on the list to peek the first node from

Returns

A pointer on the first node of the list (or NULL if none)

static inline *sys_snode_t* ***sys_slist_peek_tail**(*sys_slist_t* *list)

Peek the last node from the list.

Parameters

- **list** – A point on the list to peek the last node from

Returns
A pointer on the last node of the list (or NULL if none)

static inline bool **sys_slist_is_empty**(*sys_slist_t* *list)

Test if the given list is empty.

Parameters

- **list** – A pointer on the list to test

Returns
a boolean, true if it's empty, false otherwise

static inline *sys_snode_t* ***sys_slist_peek_next_no_check**(*sys_snode_t* *node)

Peek the next node from current node, node is not NULL.

Faster then *sys_slist_peek_next()* if node is known not to be NULL.

Parameters

- **node** – A pointer on the node where to peek the next node

Returns
a pointer on the next node (or NULL if none)

static inline *sys_snode_t* ***sys_slist_peek_next**(*sys_snode_t* *node)

Peek the next node from current node.

Parameters

- **node** – A pointer on the node where to peek the next node

Returns
a pointer on the next node (or NULL if none)

static inline void **sys_slist_prepend**(*sys_slist_t* *list, *sys_snode_t* *node)

Prepend a node to the given list.

This and other sys_slist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **node** – A pointer on the node to prepend

static inline void **sys_slist_append**(*sys_slist_t* *list, *sys_snode_t* *node)

Append a node to the given list.

This and other sys_slist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **node** – A pointer on the node to append

static inline void **sys_slist_append_list**(*sys_slist_t* *list, void *head, void *tail)

Append a list to the given list.

Append a singly-linked, NULL-terminated list consisting of nodes containing the pointer to the next node as the first element of a node, to *list*. This and other sys_slist_*() functions are not thread safe.

FIXME: Why are the element parameters void *?

Parameters

- **list** – A pointer on the list to affect
- **head** – A pointer to the first element of the list to append
- **tail** – A pointer to the last element of the list to append

static inline void **sys_slist_merge_slist**(*sys_slist_t* *list, *sys_slist_t* *list_to_append)

merge two slists, appending the second one to the first

When the operation is completed, the appending list is empty. This and other sys_slist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **list_to_append** – A pointer to the list to append.

static inline void **sys_slist_insert**(*sys_slist_t* *list, *sys_snode_t* *prev, *sys_snode_t* *node)

Insert a node to the given list.

This and other sys_slist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **prev** – A pointer on the previous node
- **node** – A pointer on the node to insert

static inline *sys_snode_t* ***sys_slist_get_not_empty**(*sys_slist_t* *list)

Fetch and remove the first node of the given list.

List must be known to be non-empty. This and other sys_slist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect

Returns

A pointer to the first node of the list

static inline *sys_snode_t* ***sys_slist_get**(*sys_slist_t* *list)

Fetch and remove the first node of the given list.

This and other sys_slist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect

Returns

A pointer to the first node of the list (or NULL if empty)

static inline void **sys_slist_remove**(*sys_slist_t* *list, *sys_snode_t* *prev_node, *sys_snode_t* *node)

Remove a node.

This and other sys_slist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **prev_node** – A pointer on the previous node (can be NULL, which means the node is the list's head)

- **node** – A pointer on the node to remove

static inline bool **sys_slist_find_and_remove**(*sys_slist_t* *list, *sys_snode_t* *node)

Find and remove a node from a list.

This and other sys_slist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **node** – A pointer on the node to remove from the list

Returns

true if node was removed

static inline bool **sys_slist_find**(*sys_slist_t* *list, *sys_snode_t* *node, *sys_snode_t* **prev)

Find if a node is already linked in a singly linked list.

This and other sys_slist_*() functions are not thread safe.

Parameters

- **list** – A pointer to the list to check
- **node** – A pointer to the node to search in the list
- **prev** – **[out]** A pointer to the previous node

Returns

true if node was found in the list, false otherwise

static inline size_t **sys_slist_len**(*sys_slist_t* *list)

Compute the size of the given list in O(n) time.

Parameters

- **list** – A pointer on the list

Returns

an integer equal to the size of the list, or 0 if empty

Flagged List API Reference

group **flagged-single-linked-list_apis**

Flagged single-linked list implementation.

Similar to *Single-linked list* with the added ability to define user "flags" bits for each node. They can be accessed and modified using the *sys_sfnode_flags_get()* and *sys_sfnode_flags_set()* APIs.

Flagged single-linked list implementation using inline macros/functions. This API is not thread safe, and thus if a list is used across threads, calls to functions must be protected with synchronization primitives.

Defines

SYS_SFLIST_FOR_EACH_NODE(__sl, __sn)

Provide the primitive to iterate on a list Note: the loop is unsafe and thus __sn should not be removed.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_SFLIST_FOR_EACH_NODE(l, n) {
    <user code>
}
```

This and other SYS_SFLIST_*() macros are not thread safe.

Parameters

- **__sl** – A pointer on a sys_sflist_t to iterate on
- **__sn** – A sys_sfnode_t pointer to peek each node of the list

SYS_SFLIST_ITERATE_FROM_NODE(__sl, __sn)

Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and thus __sn should not be removed.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_SFLIST_ITERATE_FROM_NODE(l, n) {
    <user code>
}
```

Like *SYS_SFLIST_FOR_EACH_NODE()*, but __dn already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.

This and other SYS_SFLIST_*() macros are not thread safe.

Parameters

- **__sl** – A pointer on a sys_sflist_t to iterate on
- **__sn** – A sys_sfnode_t pointer to peek each node of the list it contains the starting node, or NULL to start from the head

SYS_SFLIST_FOR_EACH_NODE_SAFE(__sl, __sn, __sns)

Provide the primitive to safely iterate on a list Note: __sn can be removed, it will not break the loop.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_SFLIST_FOR_EACH_NODE_SAFE(l, n, s) {
    <user code>
}
```

This and other SYS_SFLIST_*() macros are not thread safe.

Parameters

- **__sl** – A pointer on a sys_sflist_t to iterate on
- **__sn** – A sys_sfnode_t pointer to peek each node of the list
- **__sns** – A sys_sfnode_t pointer for the loop to run safely

SYS_SFLIST_CONTAINER(__ln, __cn, __n)

Provide the primitive to resolve the container of a list node Note: it is safe to use with NULL pointer nodes.

Parameters

- **__ln** – A pointer on a sys_sfnode_t to get its container
- **__cn** – Container struct type pointer
- **__n** – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_PEEK_HEAD_CONTAINER(__sl, __cn, __n)

Provide the primitive to peek container of the list head.

Parameters

- **__sl** – A pointer on a sys_sflist_t to peek
- **__cn** – Container struct type pointer
- **__n** – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_PEEK_TAIL_CONTAINER(__sl, __cn, __n)

Provide the primitive to peek container of the list tail.

Parameters

- **__sl** – A pointer on a sys_sflist_t to peek
- **__cn** – Container struct type pointer
- **__n** – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_PEEK_NEXT_CONTAINER(__cn, __n)

Provide the primitive to peek the next container.

Parameters

- **__cn** – Container struct type pointer
- **__n** – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_FOR_EACH_CONTAINER(__sl, __cn, __n)

Provide the primitive to iterate on a list under a container Note: the loop is unsafe and thus __cn should not be detached.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_SFLIST_FOR_EACH_CONTAINER(l, c, n) {
    <user code>
}
```

Parameters

- **__sl** – A pointer on a sys_sflist_t to iterate on
- **__cn** – A pointer to peek each entry of the list
- **__n** – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_FOR_EACH_CONTAINER_SAFE(__sl, __cn, __cns, __n)

Provide the primitive to safely iterate on a list under a container Note: __cn can be detached, it will not break the loop.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_SFLIST_FOR_EACH_NODE_SAFE(l, c, cn, n) {
    <user code>
}
```

Parameters

- **__sl** – A pointer on a sys_sflist_t to iterate on
- **__cn** – A pointer to peek each entry of the list
- **__cns** – A pointer for the loop to run safely
- **__n** – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_STATIC_INIT(ptr_to_list)
Statically initialize a flagged single-linked list.

Parameters

- **ptr_to_list** – A pointer on the list to initialize

SYS_SFLIST_FLAGS_MASK

Typedefs

typedef struct _sfnode **sys_sfnode_t**
Flagged single-linked list node structure.

typedef struct _sflist **sys_sflist_t**
Flagged single-linked list structure.

Functions

static inline void **sys_sflist_init**(*sys_sflist_t* *list)
Initialize a list.

Parameters

- **list** – A pointer on the list to initialize

static inline uint8_t **sys_sfnode_flags_get**(*sys_sfnode_t* *node)
Fetch flags value for a particular sfnode.

Parameters

- **node** – A pointer to the node to fetch flags from

Returns
The value of flags, which will be between 0 and 3 on 32-bit architectures, or between 0 and 7 on 64-bit architectures

static inline *sys_sfnode_t* ***sys_sflist_peek_head**(*sys_sflist_t* *list)
Peek the first node from the list.

Parameters

- **list** – A point on the list to peek the first node from

Returns
A pointer on the first node of the list (or NULL if none)

static inline *sys_sfnode_t* ***sys_sflist_peek_tail**(*sys_sflist_t* *list)
Peek the last node from the list.

Parameters

- **list** – A point on the list to peek the last node from

Returns
A pointer on the last node of the list (or NULL if none)

static inline void **sys_sfnode_init**(*sys_sfnode_t* *node, uint8_t flags)

Initialize an sflist node.

Set an initial flags value for this slist node, which can be a value between 0 and 3 on 32-bit architectures, or between 0 and 7 on 64-bit architectures. These flags will persist even if the node is moved around within a list, removed, or transplanted to a different slist.

This is ever so slightly faster than *sys_sfnode_flags_set()* and should only be used on a node that hasn't been added to any list.

Parameters

- **node** – A pointer to the node to set the flags on
- **flags** – The flags value to set

static inline void **sys_sfnode_flags_set**(*sys_sfnode_t* *node, uint8_t flags)

Set flags value for an sflist node.

Set a flags value for this slist node, which can be a value between 0 and 3 on 32-bit architectures, or between 0 and 7 on 64-bit architectures. These flags will persist even if the node is moved around within a list, removed, or transplanted to a different slist.

Parameters

- **node** – A pointer to the node to set the flags on
- **flags** – The flags value to set

static inline bool **sys_sflist_is_empty**(*sys_sflist_t* *list)

Test if the given list is empty.

Parameters

- **list** – A pointer on the list to test

Returns
a boolean, true if it's empty, false otherwise

static inline *sys_sfnode_t* ***sys_sflist_peek_next_no_check**(*sys_sfnode_t* *node)

Peek the next node from current node, node is not NULL.

Faster then *sys_sflist_peek_next()* if node is known not to be NULL.

Parameters

- **node** – A pointer on the node where to peek the next node

Returns
a pointer on the next node (or NULL if none)

static inline *sys_sfnode_t* ***sys_sflist_peek_next**(*sys_sfnode_t* *node)

Peek the next node from current node.

Parameters

- **node** – A pointer on the node where to peek the next node

Returns
a pointer on the next node (or NULL if none)

static inline void **sys_sflist_prepend**(*sys_sflist_t* *list, *sys_sfnode_t* *node)

Prepend a node to the given list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect

- **node** – A pointer on the node to prepend

static inline void **sys_sflist_append**(*sys_sflist_t* *list, *sys_sfnode_t* *node)

Append a node to the given list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **node** – A pointer on the node to append

static inline void **sys_sflist_append_list**(*sys_sflist_t* *list, void *head, void *tail)

Append a list to the given list.

Append a singly-linked, NULL-terminated list consisting of nodes containing the pointer to the next node as the first element of a node, to *list*. This and other sys_sflist_*() functions are not thread safe.

FIXME: Why are the element parameters void *?

Parameters

- **list** – A pointer on the list to affect
- **head** – A pointer to the first element of the list to append
- **tail** – A pointer to the last element of the list to append

static inline void **sys_sflist_merge_sflist**(*sys_sflist_t* *list, *sys_sflist_t* *list_to_append)

merge two sflists, appending the second one to the first

When the operation is completed, the appending list is empty. This and other sys_sflist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **list_to_append** – A pointer to the list to append.

static inline void **sys_sflist_insert**(*sys_sflist_t* *list, *sys_sfnode_t* *prev, *sys_sfnode_t* *node)

Insert a node to the given list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **prev** – A pointer on the previous node
- **node** – A pointer on the node to insert

static inline *sys_sfnode_t* ***sys_sflist_get_not_empty**(*sys_sflist_t* *list)

Fetch and remove the first node of the given list.

List must be known to be non-empty. This and other sys_sflist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect

Returns

A pointer to the first node of the list

static inline *sys_sfnode_t* ***sys_sflist_get**(*sys_sflist_t* *list)

Fetch and remove the first node of the given list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect

Returns
A pointer to the first node of the list (or NULL if empty)

static inline void **sys_sflist_remove**(*sys_sflist_t* *list, *sys_sfnode_t* *prev_node, *sys_sfnode_t* *node)

Remove a node.

This and other sys_sflist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **prev_node** – A pointer on the previous node (can be NULL, which means the node is the list's head)
- **node** – A pointer on the node to remove

static inline bool **sys_sflist_find_and_remove**(*sys_sflist_t* *list, *sys_sfnode_t* *node)

Find and remove a node from a list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

- **list** – A pointer on the list to affect
- **node** – A pointer on the node to remove from the list

Returns
true if node was removed

static inline size_t **sys_sflist_len**(*sys_sflist_t* *list)

Compute the size of the given list in O(n) time.

Parameters

- **list** – A pointer on the list

Returns
an integer equal to the size of the list, or 0 if empty

3.5.2 Double-linked List

Similar to the single-linked list in many respects, Zephyr includes a double-linked implementation. This provides the same algorithmic behavior for all the existing slist operations, but also allows for constant-time removal and insertion (at all points: before or after the head, tail or any internal node). To do this, the list stores two pointers per node, and thus has somewhat higher runtime code and memory space needs.

A *sys_dlist_t* struct may be instantiated by the user in any accessible memory. It must be initialized with *sys_dlist_init()* or *SYS_DLIST_STATIC_INIT* before use. The *sys_dnode_t* struct is expected to be provided by the user for any nodes added to the list (typically embedded within the struct to be tracked, as described above). It must be initialized in zeroed/bss memory or with *sys_dnode_init()* before use.

Primitive operations may retrieve the head/tail of a list and the next/prev pointers of a node with *sys_dlist_peek_head()*, *sys_dlist_peek_tail()*, *sys_dlist_peek_next()* and

sys_dlist_peek_prev(). These can all return NULL where appropriate (i.e. for empty lists, or nodes at the endpoints of the list).

A dlist can be modified in constant time by removing a node with *sys_dlist_remove()*, by adding a node to the head or tail of a list with *sys_dlist_prepend()* and *sys_dlist_append()*, or by inserting a node before an existing node with *sys_dlist_insert()*.

As for slist, each node in a dlist can be processed in a natural code block style using *SYS_DLIST_FOR_EACH_NODE*. This macro also exists in a "FROM_NODE" form which allows for iterating from a known starting point, a "SAFE" variant that allows for removing the node being inspected within the code block, a "CONTAINER" style that provides the pointer to a containing struct instead of the raw node, and a "CONTAINER_SAFE" variant that provides both properties.

Convenience utilities provided by dlist include *sys_dlist_insert_at()*, which inserts a node that linearly searches through a list to find the right insertion point, which is provided by the user as a C callback function pointer, and *sys_dnode_is_linked()*, which will affirmatively return whether or not a node is currently linked into a dlist or not (via an implementation that has zero overhead vs. the normal list processing).

Double-linked List Internals

Internally, the dlist implementation is minimal: the *sys_dlist_t* struct contains "head" and "tail" pointer fields, the *sys_dnode_t* contains "prev" and "next" pointers, and no other data is stored. But in practice the two structs are internally identical, and the list struct is inserted as a node into the list itself. This allows for a very clean symmetry of operations:

- An empty list has backpointers to itself in the list struct, which can be trivially detected.
- The head and tail of the list can be detected by comparing the prev/next pointers of a node vs. the list struct address.
- An insertion or deletion never needs to check for the special case of inserting at the head or tail. There are never any NULL pointers within the list to be avoided. Exactly the same operations are run, without tests or branches, for all list modification primitives.

Effectively, a dlist of N nodes can be thought of as a "ring" of "N+1" nodes, where one node represents the list tracking struct.

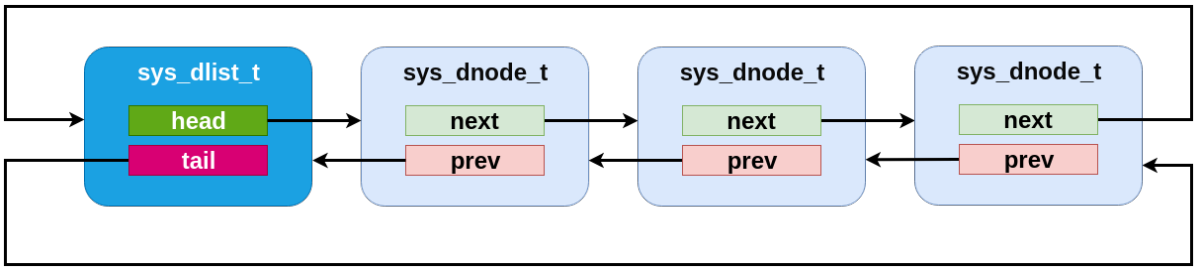

Fig. 6: A dlist containing three elements. Note that the list struct appears as a fourth "element" in the list.

Doubly-linked List API Reference

group `doubly-linked-list_apis`

Doubly-linked list implementation.

Doubly-linked list implementation using inline macros/functions. This API is not thread safe, and thus if a list is used across threads, calls to functions must be protected with synchronization primitives.

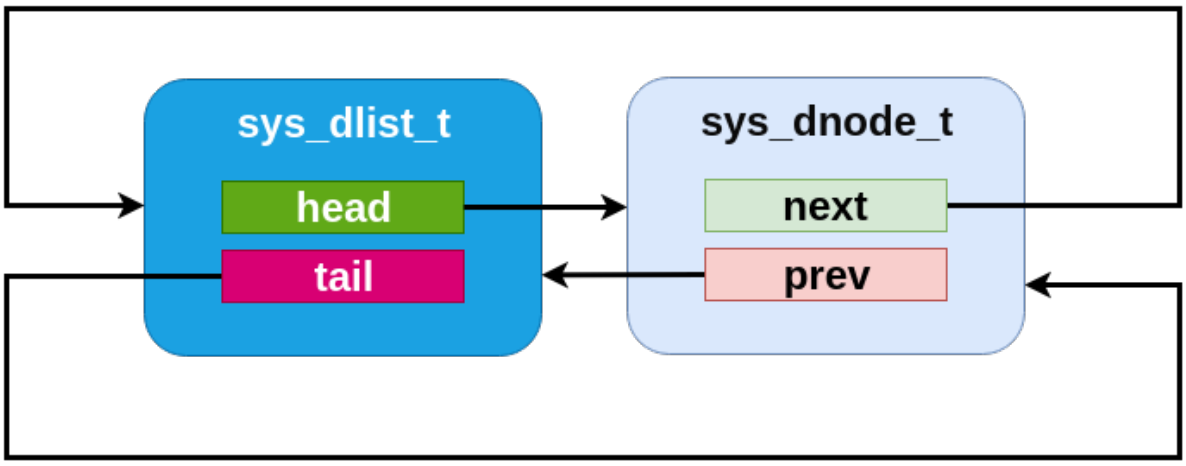

Fig. 7: An dlist containing just one element.

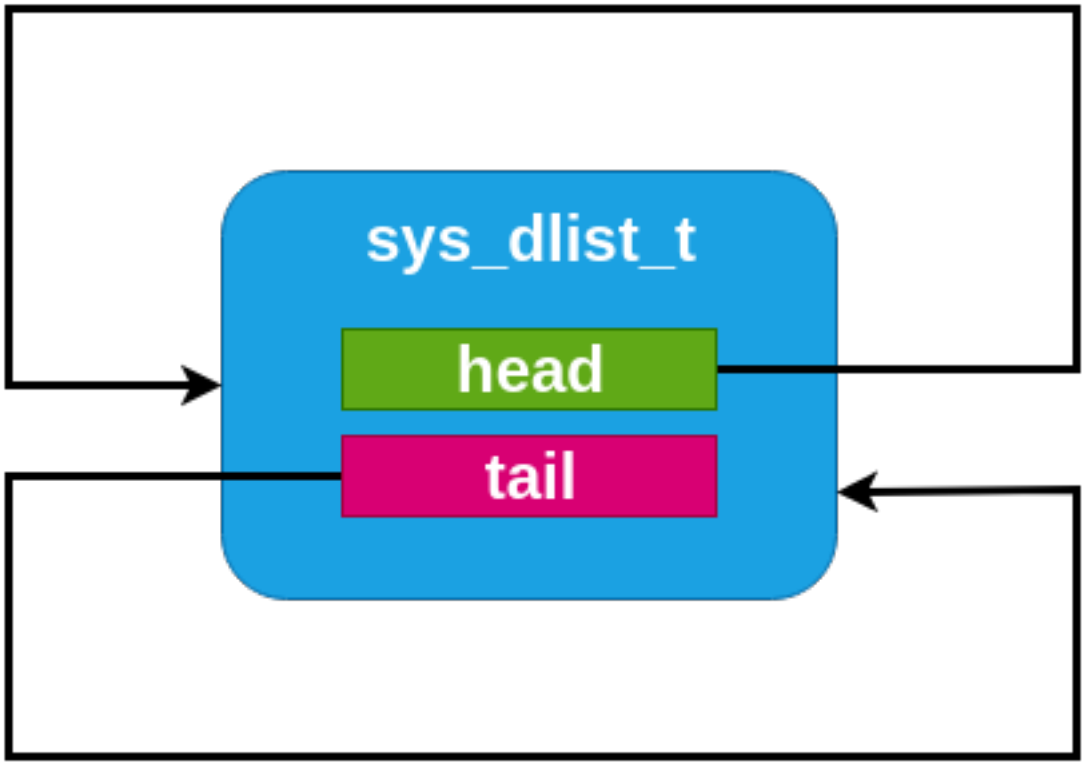

Fig. 8: An empty dlist.

The lists are expected to be initialized such that both the head and tail pointers point to the list itself. Initializing the lists in such a fashion simplifies the adding and removing of nodes to/from the list.

Defines

SYS_DLIST_FOR_EACH_NODE(__dl, __dn)

Provide the primitive to iterate on a list Note: the loop is unsafe and thus __dn should not be removed.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_DLIST_FOR_EACH_NODE(l, n) {
    <user code>
}
```

This and other SYS_DLIST_*() macros are not thread safe.

Parameters

- **__dl** – A pointer on a sys_dlist_t to iterate on
- **__dn** – A sys_dnode_t pointer to peek each node of the list

SYS_DLIST_ITERATE_FROM_NODE(__dl, __dn)

Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and thus __dn should not be removed.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_DLIST_ITERATE_FROM_NODE(l, n) {
    <user code>
}
```

Like *SYS_DLIST_FOR_EACH_NODE()*, but __dn already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.

This and other SYS_DLIST_*() macros are not thread safe.

Parameters

- **__dl** – A pointer on a sys_dlist_t to iterate on
- **__dn** – A sys_dnode_t pointer to peek each node of the list; it contains the starting node, or NULL to start from the head

SYS_DLIST_FOR_EACH_NODE_SAFE(__dl, __dn, __dns)

Provide the primitive to safely iterate on a list Note: __dn can be removed, it will not break the loop.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_DLIST_FOR_EACH_NODE_SAFE(l, n, s) {
    <user code>
}
```

This and other SYS_DLIST_*() macros are not thread safe.

Parameters

- **__dl** – A pointer on a sys_dlist_t to iterate on
- **__dn** – A sys_dnode_t pointer to peek each node of the list
- **__dns** – A sys_dnode_t pointer for the loop to run safely

SYS_DLIST_CONTAINER(__dn, __cn, __n)

Provide the primitive to resolve the container of a list node Note: it is safe to use with NULL pointer nodes.

Parameters

- **__dn** – A pointer on a sys_dnode_t to get its container
- **__cn** – Container struct type pointer
- **__n** – The field name of sys_dnode_t within the container struct

SYS_DLIST_PEEK_HEAD_CONTAINER(__dl, __cn, __n)

Provide the primitive to peek container of the list head.

Parameters

- **__dl** – A pointer on a sys_dlist_t to peek
- **__cn** – Container struct type pointer
- **__n** – The field name of sys_dnode_t within the container struct

SYS_DLIST_PEEK_NEXT_CONTAINER(__dl, __cn, __n)

Provide the primitive to peek the next container.

Parameters

- **__dl** – A pointer on a sys_dlist_t to peek
- **__cn** – Container struct type pointer
- **__n** – The field name of sys_dnode_t within the container struct

SYS_DLIST_FOR_EACH_CONTAINER(__dl, __cn, __n)

Provide the primitive to iterate on a list under a container Note: the loop is unsafe and thus __cn should not be detached.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_DLIST_FOR_EACH_CONTAINER(l, c, n) {
    <user code>
}
```

Parameters

- **__dl** – A pointer on a sys_dlist_t to iterate on
- **__cn** – A container struct type pointer to peek each entry of the list
- **__n** – The field name of sys_dnode_t within the container struct

SYS_DLIST_FOR_EACH_CONTAINER_SAFE(__dl, __cn, __cns, __n)

Provide the primitive to safely iterate on a list under a container Note: __cn can be detached, it will not break the loop.

User *MUST* add the loop statement curly braces enclosing its own code:

```
SYS_DLIST_FOR_EACH_CONTAINER_SAFE(l, c, cn, n) {
    <user code>
}
```

Parameters

- **__dl** – A pointer on a sys_dlist_t to iterate on
- **__cn** – A container struct type pointer to peek each entry of the list

- **__cns** – A container struct type pointer for the loop to run safely
- **__n** – The field name of sys_dnode_t within the container struct

SYS_DLIST_STATIC_INIT(ptr_to_list)
Static initializer for a doubly-linked list.

Typedefs

typedef struct _dnode **sys_dlist_t**
Doubly-linked list structure.

typedef struct _dnode **sys_dnode_t**
Doubly-linked list node structure.

Functions

static inline void **sys_dlist_init**(*sys_dlist_t* *list)
initialize list to its empty state

Parameters

- **list** – the doubly-linked list

static inline void **sys_dnode_init**(*sys_dnode_t* *node)
initialize node to its state when not in a list

Parameters

- **node** – the node

static inline bool **sys_dnode_is_linked**(const *sys_dnode_t* *node)
check if a node is a member of any list

Parameters

- **node** – the node

Returns
true if node is linked into a list, false if it is not

static inline bool **sys_dlist_is_head**(*sys_dlist_t* *list, *sys_dnode_t* *node)
check if a node is the list's head

Parameters

- **list** – the doubly-linked list to operate on
- **node** – the node to check

Returns
true if node is the head, false otherwise

static inline bool **sys_dlist_is_tail**(*sys_dlist_t* *list, *sys_dnode_t* *node)
check if a node is the list's tail

Parameters

- **list** – the doubly-linked list to operate on
- **node** – the node to check

Returns
true if node is the tail, false otherwise

static inline bool **sys_dlist_is_empty**(*sys_dlist_t* *list)
check if the list is empty

Parameters
- **list** – the doubly-linked list to operate on

Returns
true if empty, false otherwise

static inline bool **sys_dlist_has_multiple_nodes**(*sys_dlist_t* *list)
check if more than one node present

This and other sys_dlist_*() functions are not thread safe.

Parameters
- **list** – the doubly-linked list to operate on

Returns
true if multiple nodes, false otherwise

static inline *sys_dnode_t* ***sys_dlist_peek_head**(*sys_dlist_t* *list)
get a reference to the head item in the list

Parameters
- **list** – the doubly-linked list to operate on

Returns
a pointer to the head element, NULL if list is empty

static inline *sys_dnode_t* ***sys_dlist_peek_head_not_empty**(*sys_dlist_t* *list)
get a reference to the head item in the list

The list must be known to be non-empty.

Parameters
- **list** – the doubly-linked list to operate on

Returns
a pointer to the head element

static inline *sys_dnode_t* ***sys_dlist_peek_next_no_check**(*sys_dlist_t* *list, *sys_dnode_t* *node)
get a reference to the next item in the list, node is not NULL

Faster than *sys_dlist_peek_next()* if node is known not to be NULL.

Parameters
- **list** – the doubly-linked list to operate on
- **node** – the node from which to get the next element in the list

Returns
a pointer to the next element from a node, NULL if node is the tail

static inline *sys_dnode_t* ***sys_dlist_peek_next**(*sys_dlist_t* *list, *sys_dnode_t* *node)
get a reference to the next item in the list

Parameters
- **list** – the doubly-linked list to operate on
- **node** – the node from which to get the next element in the list

Returns
a pointer to the next element from a node, NULL if node is the tail or NULL (when node comes from reading the head of an empty list).

static inline *sys_dnode_t* ***sys_dlist_peek_prev_no_check**(*sys_dlist_t* *list, *sys_dnode_t* *node)

get a reference to the previous item in the list, node is not NULL

Faster than *sys_dlist_peek_prev()* if node is known not to be NULL.

Parameters

- **list** – the doubly-linked list to operate on
- **node** – the node from which to get the previous element in the list

Returns
a pointer to the previous element from a node, NULL if node is the tail

static inline *sys_dnode_t* ***sys_dlist_peek_prev**(*sys_dlist_t* *list, *sys_dnode_t* *node)

get a reference to the previous item in the list

Parameters

- **list** – the doubly-linked list to operate on
- **node** – the node from which to get the previous element in the list

Returns
a pointer to the previous element from a node, NULL if node is the tail or NULL (when node comes from reading the head of an empty list).

static inline *sys_dnode_t* ***sys_dlist_peek_tail**(*sys_dlist_t* *list)

get a reference to the tail item in the list

Parameters

- **list** – the doubly-linked list to operate on

Returns
a pointer to the tail element, NULL if list is empty

static inline void **sys_dlist_append**(*sys_dlist_t* *list, *sys_dnode_t* *node)

add node to tail of list

This and other sys_dlist_*() functions are not thread safe.

Parameters

- **list** – the doubly-linked list to operate on
- **node** – the element to append

static inline void **sys_dlist_prepend**(*sys_dlist_t* *list, *sys_dnode_t* *node)

add node to head of list

This and other sys_dlist_*() functions are not thread safe.

Parameters

- **list** – the doubly-linked list to operate on
- **node** – the element to append

static inline void **sys_dlist_insert**(*sys_dnode_t* *successor, *sys_dnode_t* *node)

Insert a node into a list.

Insert a node before a specified node in a dlist.

Parameters

- **successor** – the position before which "node" will be inserted
- **node** – the element to insert

static inline void **sys_dlist_insert_at**(*sys_dlist_t* *list, *sys_dnode_t* *node, int (*cond)(*sys_dnode_t* *node, void *data), void *data)

insert node at position

Insert a node in a location depending on a external condition. The cond() function checks if the node is to be inserted *before* the current node against which it is checked. This and other sys_dlist_*() functions are not thread safe.

Parameters

- **list** – the doubly-linked list to operate on
- **node** – the element to insert
- **cond** – a function that determines if the current node is the correct insert point
- **data** – parameter to cond()

static inline void **sys_dlist_remove**(*sys_dnode_t* *node)

remove a specific node from a list

The list is implicit from the node. The node must be part of a list. This and other sys_dlist_*() functions are not thread safe.

Parameters

- **node** – the node to remove

static inline *sys_dnode_t* ***sys_dlist_get**(*sys_dlist_t* *list)

get the first node in a list

This and other sys_dlist_*() functions are not thread safe.

Parameters

- **list** – the doubly-linked list to operate on

Returns
the first node in the list, NULL if list is empty

static inline size_t **sys_dlist_len**(*sys_dlist_t* *list)

Compute the size of the given list in O(n) time.

Parameters

- **list** – A pointer on the list

Returns
an integer equal to the size of the list, or 0 if empty

3.5.3 Multi Producer Single Consumer Packet Buffer

A *Multi Producer Single Consumer Packet Buffer (MPSC_PBUF)* is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that consumes the data. However, it is possible that another context may interfere to flush the data and never come back (panic case). Packet is produced in two steps: first requested amount of data is allocated, producer fills the data and commits it. Consuming a packet is also performed in two steps: consumer claims the packet, gets pointer to it and length and later on packet is freed. This approach reduces memory copying.

A *MPSC Packet Buffer* has the following key properties:

- Allocate, commit scheme used for packet producing.
- Claim, free scheme used for packet consuming.
- Allocator ensures that contiguous memory of requested length is allocated.
- Following policies can be applied when requested space cannot be allocated:
  - **Overwrite** - oldest entries are dropped until requested amount of memory can be allocated. For each dropped packet user callback is called.
  - **No overwrite** - When requested amount of space cannot be allocated, allocation fails.
- Dedicated, optimized API for storing short packets.
- Allocation with timeout.

Internals

Each packet in the buffer contains `MPSC_PBUF` specific header which is used for internal management. Header consists of 2 bit flags. In order to optimize memory usage, header can be added on top of the user header using `MPSC_PBUF_HDR` and remaining bits in the first word can be application specific. Header consists of following flags:

- valid - bit set to one when packet contains valid user packet
- busy - bit set when packet is being consumed (claimed but not free)

Header state:

valid	busy	description
0	0	space is free
1	0	valid packet
1	1	claimed valid packet
0	1	internal skip packet

Packet buffer space contains free space, valid user packets and internal skip packets. Internal skip packets indicates padding, e.g. at the end of the buffer.

Allocation Using pairs for read and write indexes, available space is determined. If space can be allocated, temporary write index is moved and pointer to a space within buffer is returned. Packet header is reset. If allocation required wrapping of the write index, a skip packet is added to the end of buffer. If space cannot be allocated and overwrite is disabled then `NULL` pointer is returned or context blocks if allocation was with timeout.

Allocation with overwrite If overwrite is enabled, oldest packets are dropped until requested amount of space can be allocated. When packets are dropped `busy` flag is checked in the header to ensure that currently consumed packet is not overwritten. In that case, skip packet is added before busy packet and packets following the busy packet are dropped. When busy packet is being freed, such situation is detected and packet is converted to skip packet to avoid double processing.

Usage

Packet header definition Packet header details can be found in include/zephyr/sys/mpsc_packet.h. API functions can be found in include/zephyr/sys/mpsc_pbuf.h. Headers are split to avoid include spam when declaring the packet.

User header structure must start with internal header:

```
#include <zephyr/sys/mpsc_packet.h>

struct foo_header {
        MPSC_PBUF_HDR;
        uint32_t length: 32 - MPSC_PBUF_HDR_BITS;
};
```

Packet buffer configuration Configuration structure contains buffer details, configuration flags and callbacks. Following callbacks are used by the packet buffer:

- Drop notification - callback called whenever a packet is dropped due to overwrite.
- Get packet length - callback to determine packet length

Packet producing Standard, two step method:

```
foo_packet *packet = mpsc_pbuf_alloc(buffer, len, K_NO_WAIT);

fill_data(packet);

mpsc_pbuf_commit(buffer, packet);
```

Performance optimized storing of small packets:

- 32 bit word packet
- 32 bit word with pointer packet

Note that since packets are written by value, they should already contain `valid` bit set in the header.

```
mpsc_pbuf_put_word(buffer, data);
mpsc_pbuf_put_word_ext(buffer, data, ptr);
```

Packet consuming Two step method:

```
foo_packet *packet = mpsc_pbuf_claim(buffer);

process(packet);

mpsc_pbuf_free(buffer, packet);
```

3.5.4 Single Producer Single Consumer Packet Buffer

A *Single Producer Single Consumer Packet Buffer (SPSC_PBUF)* is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that produces packets and a single context that consumes the data.

Implementation is focused on performance and memory footprint.

Packets are added to the buffer using `spsc_pbuf_write()` which copies a data into the buffer. If the buffer is full error is returned.

Packets are copied out of the buffer using `spsc_pbuf_read()`.

3.5.5 Balanced Red/Black Tree

For circumstances where sorted containers may become large at runtime, a list becomes problematic due to algorithmic costs of searching it. For these situations, Zephyr provides a balanced tree implementation which has runtimes on search and removal operations bounded at O(log2(N)) for a tree of size N. This is implemented using a conventional red/black tree as described by multiple academic sources.

The *rbtree* tracking struct for a rbtree may be initialized anywhere in user accessible memory. It should contain only zero bits before first use. No specific initialization API is needed or required.

Unlike a list, where position is explicit, the ordering of nodes within an rbtree must be provided as a predicate function by the user. A function of type *rb_lessthan_t()* should be assigned to the `lessthan_fn` field of the *rbtree* struct before any tree operations are attempted. This function should, as its name suggests, return a boolean True value if the first node argument is "less than" the second in the ordering desired by the tree. Note that "equal" is not allowed, nodes within a tree must have a single fixed order for the algorithm to work correctly.

As with the slist and dlist containers, nodes within an rbtree are represented as a *rbnode* structure which exists in user-managed memory, typically embedded within the data structure being tracked in the tree. Unlike the list code, the data within an rbnode is entirely opaque. It is not possible for the user to extract the binary tree topology and "manually" traverse the tree as it is for a list.

Nodes can be inserted into a tree with *rb_insert()* and removed with *rb_remove()*. Access to the "first" and "last" nodes within a tree (in the sense of the order defined by the comparison function) is provided by *rb_get_min()* and *rb_get_max()*. There is also a predicate, *rb_contains()*, which returns a boolean True if the provided node pointer exists as an element within the tree. As described above, all of these routines are guaranteed to have at most log time complexity in the size of the tree.

There are two mechanisms provided for enumerating all elements in an rbtree. The first, *rb_walk()*, is a simple callback implementation where the caller specifies a C function pointer and an untyped argument to be passed to it, and the tree code calls that function for each node in order. This has the advantage of a very simple implementation, at the cost of a somewhat more cumbersome API for the user (not unlike ISO C's `bsearch()` routine). It is a recursive implementation, however, and is thus not always available in environments that forbid the use of unbounded stack techniques like recursion.

There is also a *RB_FOR_EACH* iterator provided, which, like the similar APIs for the lists, works to iterate over a list in a more natural way, using a nested code block instead of a callback. It is also nonrecursive, though it requires log-sized space on the stack by default (however, this can be configured to use a fixed/maximally size buffer instead where needed to avoid the dynamic allocation). As with the lists, this is also available in a *RB_FOR_EACH_CONTAINER* variant which enumerates using a pointer to a container field and not the raw node pointer.

Tree Internals

As described, the Zephyr rbtree implementation is a conventional red/black tree as described pervasively in academic sources. Low level details about the algorithm are out of scope for this document, as they match existing conventions. This discussion will be limited to details notable or specific to the Zephyr implementation.

The core invariant guaranteed by the tree is that the path from the root of the tree to any leaf is no more than twice as long as the path to any other leaf. This is achieved by associating one bit of "color" with each node, either red or black, and enforcing a rule that no red child can be a child of another red child (i.e. that the number of black nodes on any path to the root must be the same, and that no more than that number of "extra" red nodes may be present). This rule is enforced by a set of rotation rules used to "fix" trees following modification.

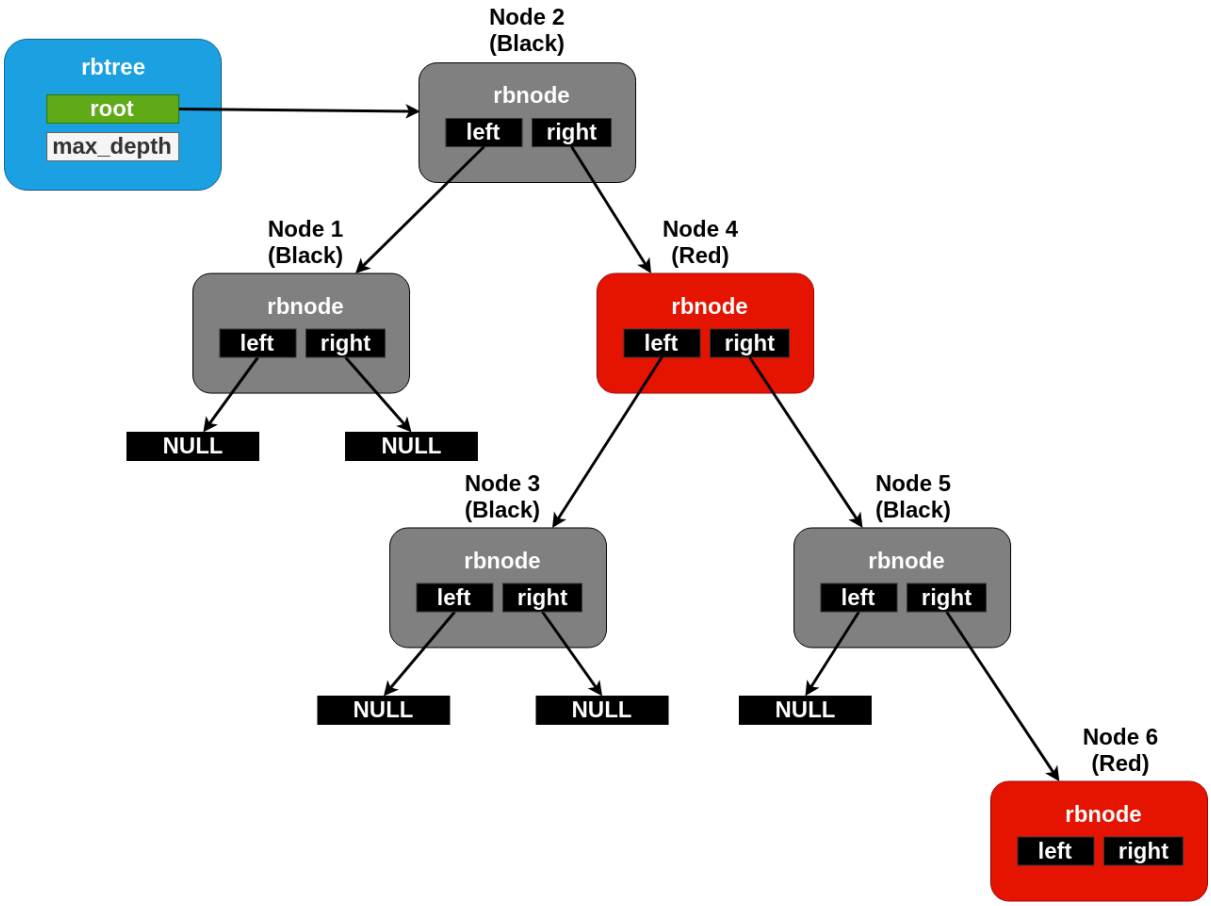

Fig. 9: A maximally unbalanced rbtree with a black height of two. No more nodes can be added underneath the rightmost node without rebalancing.

These rotations are conceptually implemented on top of a primitive that "swaps" the position of one node with another in the list. Typical implementations effect this by simply swapping the nodes internal "data" pointers, but because the Zephyr *rbnode* is intrusive, that cannot work. Zephyr must include somewhat more elaborate code to handle the edge cases (for example, one swapped node can be the root, or the two may already be parent/child).

The *rbnode* struct for a Zephyr rbtree contains only two pointers, representing the "left", and "right" children of a node within the binary tree. Traversal of a tree for rebalancing following modification, however, routinely requires the ability to iterate "upwards" from a node as well. It is very common for red/black trees in the industry to store a third "parent" pointer for this purpose. Zephyr avoids this requirement by building a "stack" of node pointers locally as it traverses downward through the tree and updating it appropriately as modifications are made. So a Zephyr rbtree can be implemented with no more runtime storage overhead than a dlist.

These properties, of a balanced tree data structure that works with only two pointers of data per node and that works without any need for a memory allocation API, are quite rare in the industry and are somewhat unique to Zephyr.

Red/Black Tree API Reference

group `rbtree_apis`

Balanced Red/Black Tree implementation.

This implements an intrusive balanced tree that guarantees O(log2(N)) runtime for all operations and amortized O(1) behavior for creation and destruction of whole trees. The algorithms and naming are conventional per existing academic and didactic implementations, c.f.:

https://en.wikipedia.org/wiki/Red%E2%80%93black_tree

The implementation is size-optimized to prioritize runtime memory usage. The data structure is intrusive, which is to say the *rbnode* handle is intended to be placed in a separate struct, in the same way as with other such structures (e.g. Zephyr's *Doubly-linked list*), and requires no data pointer to be stored in the node. The color bit is unioned with a pointer (fairly common for such libraries). Most notably, there is no "parent" pointer stored in the node, the upper structure of the tree being generated dynamically via a stack as the tree is recursed. So the overall memory overhead of a node is just two pointers, identical with a doubly-linked list.

Defines

`RB_FOR_EACH`(tree, node)

Walk a tree in-order without recursing.

While *rb_walk()* is very simple, recursing on the C stack can be clumsy for some purposes and on some architectures wastes significant memory in stack frames. This macro implements a non-recursive "foreach" loop that can iterate directly on the tree, at a moderate cost in code size.

Note that the resulting loop is not safe against modifications to the tree. Changes to the tree structure during the loop will produce incorrect results, as nodes may be skipped or duplicated. Unlike linked lists, no _SAFE variant exists.

Note also that the macro expands its arguments multiple times, so they should not be expressions with side effects.

Parameters

- `tree` – A pointer to a struct rbtree to walk

- **node** – The symbol name of a local struct rbnode* variable to use as the iterator

RB_FOR_EACH_CONTAINER(tree, node, field)

Loop over rbtree with implicit container field logic.

As for *RB_FOR_EACH()*, but "node" can have an arbitrary type containing a struct rbnode.

Parameters

- **tree** – A pointer to a struct rbtree to walk
- **node** – The symbol name of a local iterator
- **field** – The field name of a struct rbnode inside node

Typedefs

typedef bool (*rb_lessthan_t)(struct *rbnode* *a, struct *rbnode* *b)

Red/black tree comparison predicate.

Compares the two nodes and returns true if node A is strictly less than B according to the tree's sorting criteria, false otherwise.

Note that during insert, the new node being inserted will always be "A", where "B" is the existing node within the tree against which it is being compared. This trait can be used (with care!) to implement "most/least recently added" semantics between nodes which would otherwise compare as equal.

typedef void (*rb_visit_t)(struct *rbnode* *node, void *cookie)

Prototype for node visitor callback.

Param node
Node being visited

Param cookie
User-specified data

Functions

void rb_insert(struct *rbtree* *tree, struct *rbnode* *node)

Insert node into tree.

void rb_remove(struct *rbtree* *tree, struct *rbnode* *node)

Remove node from tree.

static inline struct *rbnode* *rb_get_min(struct *rbtree* *tree)

Returns the lowest-sorted member of the tree.

static inline struct *rbnode* *rb_get_max(struct *rbtree* *tree)

Returns the highest-sorted member of the tree.

bool rb_contains(struct *rbtree* *tree, struct *rbnode* *node)

Returns true if the given node is part of the tree.

Note that this does not internally dereference the node pointer (though the tree's lessthan callback might!), it just tests it for equality with items in the tree. So it's feasible to use this to implement a "set" construct by simply testing the pointer value itself.

static inline void **rb_walk**(struct *rbtree* *tree, *rb_visit_t* visit_fn, void *cookie)

Walk/enumerate a rbtree.

Very simple recursive enumeration. Low code size, but requiring a separate function can be clumsy for the user and there is no way to break out of the loop early. See RB_FOR_EACH for an iterative implementation.

struct **rbnode**

#include <*rb.h*> Balanced red/black tree node structure.

struct **rbtree**

#include <*rb.h*> Balanced red/black tree structure.

Public Members

struct *rbnode* ***root**

Root node of the tree.

rb_lessthan_t **lessthan_fn**

Comparison function for nodes in the tree.

3.5.6 Ring Buffers

A *ring buffer* is a circular buffer, whose contents are stored in first-in-first-out order.

For circumstances where an application needs to implement asynchronous "streaming" copying of data, Zephyr provides a `struct ring_buf` abstraction to manage copies of such data in and out of a shared buffer of memory.

Two content data modes are supported:

- **Byte mode**: raw bytes can be enqueued and dequeued.
- **Data item mode**: Multiple 32-bit word data items with metadata can be enqueued and dequeued from the ring buffer in chunks of up to 1020 bytes. Each data item also has two associated metadata values: a type identifier and a 16-bit integer value, both of which are application-specific.

While the underlying data structure is the same, it is not legal to mix these two modes on a single ring buffer instance. A ring buffer initialized with a byte count must be used only with the "bytes" API, one initialized with a word count must use the "items" calls.

- *Concepts*
  - *Byte mode*
  - *Data item mode*
  - *Concurrency*
  - *Internal Operation*
- *Implementation*
  - *Defining a Ring Buffer*
  - *Enqueuing Data*

  - *Retrieving Data*
- *Configuration Options*
- *API Reference*

Concepts

Any number of ring buffers can be defined (limited only by available RAM). Each ring buffer is referenced by its memory address.

A ring buffer has the following key properties:

- A **data buffer** of bytes or 32-bit words. The data buffer contains the raw bytes or 32-bit words that have been added to the ring buffer but not yet removed.
- A **data buffer size**, measured in bytes or 32-bit words. This governs the maximum amount of data (including possible metadata values) the ring buffer can hold.

A ring buffer must be initialized before it can be used. This sets its data buffer to empty.

A `struct ring_buf` may be placed anywhere in user-accessible memory, and must be initialized with *`ring_buf_init()`* or *`ring_buf_item_init()`* before use. This must be provided a region of user-controlled memory for use as the buffer itself. Note carefully that the units of the size of the buffer passed change (either bytes or words) depending on how the ring buffer will be used later. Macros for combining these steps in a single static declaration exist for convenience. *`RING_BUF_DECLARE`* will declare and statically initialize a ring buffer with a specified byte count, where *`RING_BUF_ITEM_DECLARE`* will declare and statically initialize a buffer with a given count of 32 bit words. *`RING_BUF_ITEM_SIZEOF`* will compute the size in 32-bit words corresponding to a type or an expression. Note: rounds up if the size is not a multiple of 32 bits.

"Bytes" data may be copied into the ring buffer using *`ring_buf_put()`*, passing a data pointer and byte count. These bytes will be copied into the buffer in order, as many as will fit in the allocated buffer. The total number of bytes copied (which may be fewer than provided) will be returned. Likewise *`ring_buf_get()`* will copy bytes out of the ring buffer in the order that they were written, into a user-provided buffer, returning the number of bytes that were transferred.

To avoid multiply-copied-data situations, a "claim" API exists for byte mode. *`ring_buf_put_claim()`* takes a byte size value from the user and returns a pointer to memory internal to the ring buffer that can be used to receive those bytes, along with a size of the contiguous internal region (which may be smaller than requested). The user can then copy data into that region at a later time without assembling all the bytes in a single region first. When complete, *`ring_buf_put_finish()`* can be used to signal the buffer that the transfer is complete, passing the number of bytes actually transferred. At this point a new transfer can be initiated. Similarly, *`ring_buf_get_claim()`* returns a pointer to internal ring buffer data from which the user can read without making a verbatim copy, and *`ring_buf_get_finish()`* signals the buffer with how many bytes have been consumed and allows for a new transfer to begin.

"Items" mode works similarly to bytes mode, except that all transfers are in units of 32 bit words and all memory is assumed to be aligned on 32 bit boundaries. The write and read operations are *`ring_buf_item_put()`* and *`ring_buf_item_get()`*, and work otherwise identically to the bytes mode APIs. There no "claim" API provided for items mode. One important difference is that unlike *`ring_buf_put()`*, *`ring_buf_item_put()`* will not do a partial transfer; it will return an error in the case where the provided data does not fit in its entirety.

The user can manage the capacity of a ring buffer without modifying it using either *`ring_buf_space_get()`* or *`ring_buf_item_space_get()`* which returns the number of free bytes or free 32-bit item words respectively, or by testing the *`ring_buf_is_empty()`* predicate.

Finally, a *ring_buf_reset()* call exists to immediately empty a ring buffer, discarding the tracking of any bytes or items already written to the buffer. It does not modify the memory contents of the buffer itself, however.

Byte mode A **byte mode** ring buffer instance is declared using *RING_BUF_DECLARE()* and accessed using: *ring_buf_put_claim()*, *ring_buf_put_finish()*, *ring_buf_get_claim()*, *ring_buf_get_finish()*, *ring_buf_put()* and *ring_buf_get()*.

Data can be copied into the ring buffer (see *ring_buf_put()*) or ring buffer memory can be used directly by the user. In the latter case, the operation is split into three stages:

1. allocating the buffer (*ring_buf_put_claim()*) when user requests the destination location where data can be written.
2. writing the data by the user (e.g. buffer written by DMA).
3. indicating the amount of data written to the provided buffer (*ring_buf_put_finish()*). The amount can be less than or equal to the allocated amount.

Data can be retrieved from a ring buffer through copying (see *ring_buf_get()*) or accessed directly by address. In the latter case, the operation is split into three stages:

1. retrieving source location with valid data written to a ring buffer (see *ring_buf_get_claim()*).
2. processing data
3. freeing processed data (see *ring_buf_get_finish()*). The amount freed can be less than or equal or to the retrieved amount.

Data item mode A **data item mode** ring buffer instance is declared using *RING_BUF_ITEM_DECLARE()* and accessed using *ring_buf_item_put()* and *ring_buf_item_get()*.

A ring buffer **data item** is an array of 32-bit words from 0 to 1020 bytes in length. When a data item is **enqueued** (*ring_buf_item_put()*) its contents are copied to the data buffer, along with its associated metadata values (which occupy one additional 32-bit word). If the ring buffer has insufficient space to hold the new data item the enqueue operation fails.

A data item is **dequeued** (*ring_buf_item_get()*) from a ring buffer by removing the oldest enqueued item. The contents of the dequeued data item, as well as its two metadata values, are copied to areas supplied by the retriever. If the ring buffer is empty, or if the data array supplied by the retriever is not large enough to hold the data item's data, the dequeue operation fails.

Concurrency The ring buffer APIs do not provide any concurrency control. Depending on usage (particularly with respect to number of concurrent readers/writers) applications may need to protect the ring buffer with mutexes and/or use semaphores to notify consumers that there is data to read.

For the trivial case of one producer and one consumer, concurrency control shouldn't be needed.

Internal Operation Data streamed through a ring buffer is always written to the next byte within the buffer, wrapping around to the first element after reaching the end, thus the "ring" structure. Internally, the `struct ring_buf` contains its own buffer pointer and its size, and also a set of "head" and "tail" indices representing where the next read and write operations may occur.

This boundary is invisible to the user using the normal put/get APIs, but becomes a barrier to the "claim" API, because obviously no contiguous region can be returned that crosses the end of the buffer. This can be surprising to application code, and produce performance artifacts when transfers need to happen close to the end of the buffer, as the number of calls to claim/finish needs to double for such transfers.

Implementation

Defining a Ring Buffer A ring buffer is defined using a variable of type *ring_buf*. It must then be initialized by calling *ring_buf_init()* or *ring_buf_item_init()*.

The following code defines and initializes an empty **data item mode** ring buffer (which is part of a larger data structure). The ring buffer's data buffer is capable of holding 64 words of data and metadata information.

```
#define MY_RING_BUF_WORDS 64

struct my_struct {
    struct ring_buf rb;
    uint32_t buffer[MY_RING_BUF_WORDS];
    ...
};
struct my_struct ms;

void init_my_struct {
    ring_buf_item_init(&ms.rb, MY_RING_BUF_WORDS, ms.buffer);
    ...
}
```

Alternatively, a ring buffer can be defined and initialized at compile time using one of two macros at file scope. Each macro defines both the ring buffer itself and its data buffer.

The following code defines a **data item mode** ring buffer:

```
#define MY_RING_BUF_WORDS 93
RING_BUF_ITEM_DECLARE(my_ring_buf, MY_RING_BUF_WORDS);
```

The following code defines a ring buffer intended to be used for raw bytes:

```
#define MY_RING_BUF_BYTES 93
RING_BUF_DECLARE(my_ring_buf, MY_RING_BUF_BYTES);
```

Enqueuing Data Bytes are copied to a **byte mode** ring buffer by calling *ring_buf_put()*.

```
uint8_t my_data[MY_RING_BUF_BYTES];
uint32_t ret;

ret = ring_buf_put(&ring_buf, my_data, MY_RING_BUF_BYTES);
if (ret != MY_RING_BUF_BYTES) {
    /* not enough room, partial copy. */
    ...
}
```

Data can be added to a **byte mode** ring buffer by directly accessing the ring buffer's memory. For example:

```
uint32_t size;
uint32_t rx_size;
uint8_t *data;
int err;

/* Allocate buffer within a ring buffer memory. */
size = ring_buf_put_claim(&ring_buf, &data, MY_RING_BUF_BYTES);

/* Work directly on a ring buffer memory. */
rx_size = uart_rx(data, size);
```

(continues on next page)

(continued from previous page)

```
/* Indicate amount of valid data. rx_size can be equal or less than size. */
err = ring_buf_put_finish(&ring_buf, rx_size);
if (err != 0) {
    /* This shouldn't happen unless rx_size > size */
    ...
}
```

A data item is added to a ring buffer by calling *ring_buf_item_put()*.

```
uint32_t data[MY_DATA_WORDS];
int ret;

ret = ring_buf_item_put(&ring_buf, TYPE_FOO, 0, data, MY_DATA_WORDS);
if (ret == -EMSGSIZE) {
    /* not enough room for the data item */
    ...
}
```

If the data item requires only the type or application-specific integer value (i.e. it has no data array), a size of 0 and data pointer of NULL can be specified.

```
int ret;

ret = ring_buf_item_put(&ring_buf, TYPE_BAR, 17, NULL, 0);
if (ret == -EMSGSIZE) {
    /* not enough room for the data item */
    ...
}
```

Retrieving Data Data bytes are copied out from a **byte mode** ring buffer by calling *ring_buf_get()*. For example:

```
uint8_t my_data[MY_DATA_BYTES];
size_t  ret;

ret = ring_buf_get(&ring_buf, my_data, sizeof(my_data));
if (ret != sizeof(my_data)) {
    /* Fewer bytes copied. */
} else {
    /* Requested amount of bytes retrieved. */
    ...
}
```

Data can be retrieved from a **byte mode** ring buffer by direct operations on the ring buffer's memory. For example:

```
uint32_t size;
uint32_t proc_size;
uint8_t *data;
int err;

/* Get buffer within a ring buffer memory. */
size = ring_buf_get_claim(&ring_buf, &data, MY_RING_BUF_BYTES);

/* Work directly on a ring buffer memory. */
proc_size = process(data, size);

/* Indicate amount of data that can be freed. proc_size can be equal or less
 * than size.
```

(continues on next page)

(continued from previous page)

```
 */
err = ring_buf_get_finish(&ring_buf, proc_size);
if (err != 0) {
    /* proc_size exceeds amount of valid data in a ring buffer. */
    ...
}
```

A data item is removed from a ring buffer by calling *ring_buf_item_get()*.

```
uint32_t my_data[MY_DATA_WORDS];
uint16_t my_type;
uint8_t  my_value;
uint8_t  my_size;
int ret;

my_size = MY_DATA_WORDS;
ret = ring_buf_item_get(&ring_buf, &my_type, &my_value, my_data, &my_size);
if (ret == -EMSGSIZE) {
    printk("Buffer is too small, need %d uint32_t\n", my_size);
} else if (ret == -EAGAIN) {
    printk("Ring buffer is empty\n");
} else {
    printk("Got item of type %u value &u of size %u dwords\n",
           my_type, my_value, my_size);
    ...
}
```

Configuration Options

Related configuration options:

- CONFIG_RING_BUFFER: Enable ring buffer.

API Reference

The following ring buffer APIs are provided by include/zephyr/sys/ring_buffer.h:

group **ring_buffer_apis**

Simple ring buffer implementation.

Defines

RING_BUF_DECLARE(name, size8)

Define and initialize a ring buffer for byte data.

This macro establishes a ring buffer of an arbitrary size. The basic storage unit is a byte.

The ring buffer can be accessed outside the module where it is defined using:

```
extern struct ring_buf <name>;
```

Parameters

- **name** – Name of the ring buffer.
- **size8** – Size of ring buffer (in bytes).

RING_BUF_ITEM_DECLARE(name, size32)

Define and initialize an “item based” ring buffer.

This macro establishes an “item based” ring buffer. Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

The ring buffer can be accessed outside the module where it is defined using:

```
extern struct ring_buf <name>;
```

Parameters

- **name** – Name of the ring buffer.
- **size32** – Size of ring buffer (in 32-bit words).

RING_BUF_ITEM_DECLARE_SIZE(name, size32)

Define and initialize an “item based” ring buffer.

This exists for backward compatibility reasons. *RING_BUF_ITEM_DECLARE* should be used instead.

Parameters

- **name** – Name of the ring buffer.
- **size32** – Size of ring buffer (in 32-bit words).

RING_BUF_ITEM_DECLARE_POW2(name, pow)

Define and initialize a power-of-2 sized “item based” ring buffer.

This macro establishes an “item based” ring buffer by specifying its size using a power of 2. This exists mainly for backward compatibility reasons. *RING_BUF_ITEM_DECLARE* should be used instead.

Parameters

- **name** – Name of the ring buffer.
- **pow** – Ring buffer size exponent.

RING_BUF_ITEM_SIZEOF(expr)

Compute the ring buffer size in 32-bit needed to store an element.

The argument can be a type or an expression. Note: rounds up if the size is not a multiple of 32 bits.

Parameters

- **expr** – Expression or type to compute the size of

Functions

static inline void **ring_buf_internal_reset**(struct *ring_buf* *buf, int32_t value)

Function to force *ring_buf* internal states to given value.

Any value other than 0 makes sense only in validation testing context.

static inline void **ring_buf_init**(struct *ring_buf* *buf, uint32_t size, uint8_t *data)

Initialize a ring buffer for byte data.

This routine initializes a ring buffer, prior to its first use. It is only used for ring buffers not defined using RING_BUF_DECLARE.

Parameters

- **buf** – Address of ring buffer.
- **size** – Ring buffer size (in bytes).
- **data** – Ring buffer data area (uint8_t data[size]).

static inline void **ring_buf_item_init**(struct *ring_buf* *buf, uint32_t size, uint32_t *data)

Initialize an “item based” ring buffer.

This routine initializes a ring buffer, prior to its first use. It is only used for ring buffers not defined using RING_BUF_ITEM_DECLARE.

Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

Parameters

- **buf** – Address of ring buffer.
- **size** – Ring buffer size (in 32-bit words)
- **data** – Ring buffer data area (uint32_t data[size]).

static inline bool **ring_buf_is_empty**(struct *ring_buf* *buf)

Determine if a ring buffer is empty.

Parameters

- **buf** – Address of ring buffer.

Returns

true if the ring buffer is empty, or false if not.

static inline void **ring_buf_reset**(struct *ring_buf* *buf)

Reset ring buffer state.

Parameters

- **buf** – Address of ring buffer.

static inline uint32_t **ring_buf_space_get**(struct *ring_buf* *buf)

Determine free space in a ring buffer.

Parameters

- **buf** – Address of ring buffer.

Returns

Ring buffer free space (in bytes).

static inline uint32_t **ring_buf_item_space_get**(struct *ring_buf* *buf)

Determine free space in an “item based” ring buffer.

Parameters

- **buf** – Address of ring buffer.

Returns

Ring buffer free space (in 32-bit words).

static inline uint32_t **ring_buf_capacity_get**(struct *ring_buf* *buf)

Return ring buffer capacity.

Parameters

- **buf** – Address of ring buffer.

Returns
Ring buffer capacity (in bytes).

static inline uint32_t **ring_buf_size_get**(struct *ring_buf* *buf)

Determine used space in a ring buffer.

Parameters

- **buf** – Address of ring buffer.

Returns
Ring buffer space used (in bytes).

uint32_t **ring_buf_put_claim**(struct *ring_buf* *buf, uint8_t **data, uint32_t size)

Allocate buffer for writing data to a ring buffer.

With this routine, memory copying can be reduced since internal ring buffer can be used directly by the user. Once data is written to allocated area number of bytes written must be confirmed (see *ring_buf_put_finish*).

Warning

Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

Warning

Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters

- **buf** – **[in]** Address of ring buffer.
- **data** – **[out]** Pointer to the address. It is set to a location within ring buffer.
- **size** – **[in]** Requested allocation size (in bytes).

Returns
Size of allocated buffer which can be smaller than requested if there is not enough free space or buffer wraps.

int **ring_buf_put_finish**(struct *ring_buf* *buf, uint32_t size)

Indicate number of bytes written to allocated buffers.

The number of bytes must be equal to or lower than the sum corresponding to all preceding *ring_buf_put_claim* invocations (or even 0). Surplus bytes will be returned to the available free buffer space.

Warning

Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

Warning

Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters

- `buf` – Address of ring buffer.
- `size` – Number of valid bytes in the allocated buffers.

Return values

- `0` – Successful operation.
- `-EINVAL` – Provided *size* exceeds free space in the ring buffer.

uint32_t **ring_buf_put**(struct *ring_buf* *buf, const uint8_t *data, uint32_t size)

Write (copy) data to a ring buffer.

This routine writes data to a ring buffer *buf*.

Warning

Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

Warning

Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters

- `buf` – Address of ring buffer.
- `data` – Address of data.
- `size` – Data size (in bytes).

Return values

`Number` – of bytes written.

uint32_t **ring_buf_get_claim**(struct *ring_buf* *buf, uint8_t **data, uint32_t size)

Get address of a valid data in a ring buffer.

With this routine, memory copying can be reduced since internal ring buffer can be used directly by the user. Once data is processed it must be freed using *ring_buf_get_finish*.

Warning

Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning

Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters

- `buf` – **[in]** Address of ring buffer.
- `data` – **[out]** Pointer to the address. It is set to a location within ring buffer.
- `size` – **[in]** Requested size (in bytes).

Returns

Number of valid bytes in the provided buffer which can be smaller than requested if there is not enough free space or buffer wraps.

int `ring_buf_get_finish`(struct *ring_buf* *buf, uint32_t size)

Indicate number of bytes read from claimed buffer.

The number of bytes must be equal or lower than the sum corresponding to all preceding *ring_buf_get_claim* invocations (or even 0). Surplus bytes will remain available in the buffer.

Warning

Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning

Ring buffer instance should not mix byte access and item mode (calls prefixed with ring_buf_item_).

Parameters

- `buf` – Address of ring buffer.
- `size` – Number of bytes that can be freed.

Return values

- `0` – Successful operation.
- `-EINVAL` – Provided *size* exceeds valid bytes in the ring buffer.

uint32_t `ring_buf_get`(struct *ring_buf* *buf, uint8_t *data, uint32_t size)

Read data from a ring buffer.

This routine reads data from a ring buffer *buf*.

Warning

Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning

Ring buffer instance should not mix byte access and item mode (calls prefixed with ring_buf_item_).

Parameters

- `buf` – Address of ring buffer.
- `data` – Address of the output buffer. Can be NULL to discard data.
- `size` – Data size (in bytes).

Return values

`Number` – of bytes written to the output buffer.

uint32_t `ring_buf_peek`(struct *ring_buf* *buf, uint8_t *data, uint32_t size)

Peek at data from a ring buffer.

This routine reads data from a ring buffer *buf* without removal.

Warning

Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning

Ring buffer instance should not mix byte access and item mode (calls prefixed with ring_buf_item_).

Warning

Multiple calls to peek will result in the same data being 'peeked' multiple times. To remove data, use either *ring_buf_get* or *ring_buf_get_claim* followed by *ring_buf_get_finish* with a non-zero `size`.

Parameters

- `buf` – Address of ring buffer.
- `data` – Address of the output buffer. Cannot be NULL.
- `size` – Data size (in bytes).

Return values

`Number` – of bytes written to the output buffer.

int `ring_buf_item_put`(struct *ring_buf* *buf, uint16_t type, uint8_t value, uint32_t *data, uint8_t size32)

Write a data item to a ring buffer.

This routine writes a data item to ring buffer *buf*. The data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

Warning

Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

Parameters

- `buf` – Address of ring buffer.
- `type` – Data item's type identifier (application specific).
- `value` – Data item's integer value (application specific).
- `data` – Address of data item.
- `size32` – Data item size (number of 32-bit words).

Return values

- `0` – Data item was written.
- `-EMSGSIZE` – Ring buffer has insufficient free space.

int `ring_buf_item_get`(struct *ring_buf* *buf, uint16_t *type, uint8_t *value, uint32_t *data, uint8_t *size32)

Read a data item from a ring buffer.

This routine reads a data item from ring buffer *buf*. The data item is an array of 32-bit words (up to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

Warning

Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Parameters

- `buf` – Address of ring buffer.
- `type` – Area to store the data item's type identifier.
- `value` – Area to store the data item's integer value.
- `data` – Area to store the data item. Can be NULL to discard data.
- `size32` – Size of the data item storage area (number of 32-bit chunks).

Return values

- `0` – Data item was fetched; *size32* now contains the number of 32-bit words read into data area *data*.
- `-EAGAIN` – Ring buffer is empty.
- `-EMSGSIZE` – Data area *data* is too small; *size32* now contains the number of 32-bit words needed.

struct `ring_buf`

#include <ring_buffer.h> A structure to represent a ring buffer.

3.5.7 Multi Producer Single Consumer Lock Free Queue

A *Multi Producer Single Consumer Lock Free Queue (MPSC)* is an lockfree intrusive queue based on atomic pointer swaps as described by Dmitry Vyukov at 1024cores.

API Reference

group `mpsc_lockfree`

Multiple Producer Single Consumer (MPSC) Lockfree Queue API.

Defines

`mpsc_ptr_get`(ptr)

`mpsc_ptr_set`(ptr, val)

`mpsc_ptr_set_get`(ptr, val)

`MPSC_INIT`(symbol)

Static initializer for a mpsc queue.

Since the queue is

Parameters

- `symbol` – name of the queue

Typedefs

typedef atomic_ptr_t `mpsc_ptr_t`

Functions

static inline void `mpsc_init`(struct *mpsc* *q)

Initialize queue.

Parameters

- `q` – Queue to initialize or reset

ALWAYS_INLINE static void `mpsc_push`(struct *mpsc* *q, struct *mpsc_node* *n)

Push a node.

Parameters

- `q` – Queue to push the node to
- `n` – Node to push into the queue

static inline struct *mpsc_node* *`mpsc_pop`(struct *mpsc* *q)

Pop a node off of the list.

Return values

- `NULL` – When no node is available
- `node` – When node is available

struct `mpsc_node`

#include <*mpsc_lockfree.h*> Queue member.

struct `mpsc`

#include <*mpsc_lockfree.h*> MPSC Queue.

3.5.8 Single Producer Single Consumer Lock Free Queue

A *Single Producer Single Consumer Lock Free Queue (SPSC)* is a lock free atomic ring buffer based queue.

API Reference

group `spsc_lockfree`

Single Producer Single Consumer (SPSC) Lockfree Queue API.

Defines

`SPSC_INITIALIZER`(sz, buf)

Statically initialize an spsc.

Parameters

- `sz` – Size of the spsc, must be power of 2 (ex: 2, 4, 8)
- `buf` – Buffer pointer

`SPSC_DECLARE`(name, type)

Declare an anonymous struct type for an spsc.

Parameters

- `name` – Name of the spsc symbol to be provided
- `type` – Type stored in the spsc

`SPSC_DEFINE`(name, type, sz)

Define an spsc with a fixed size.

Parameters

- `name` – Name of the spsc symbol to be provided
- `type` – Type stored in the spsc
- `sz` – Size of the spsc, must be power of 2 (ex: 2, 4, 8)

`spsc_size`(spsc)

Size of the SPSC queue.

Parameters

- `spsc` – SPSC reference

`spsc_reset`(spsc)

Initialize/reset a spsc such that its empty.

Note that this is not safe to do while being used in a producer/consumer situation with multiple calling contexts (isrs/threads).

Parameters

- **spsc** – SPSC to initialize/reset

`spsc_acquire`(spsc)

Acquire an element to produce from the SPSC.

Parameters

- **spsc** – SPSC to acquire an element from for producing

Returns

A pointer to the acquired element or null if the spsc is full

`spsc_produce`(spsc)

Produce one previously acquired element to the SPSC.

This makes one element available to the consumer immediately

Parameters

- **spsc** – SPSC to produce the previously acquired element or do nothing

`spsc_produce_all`(spsc)

Produce all previously acquired elements to the SPSC.

This makes all previous acquired elements available to the consumer immediately

Parameters

- **spsc** – SPSC to produce all previously acquired elements or do nothing

`spsc_drop_all`(spsc)

Drop all previously acquired elements.

This makes all previous acquired elements available to be acquired again

Parameters

- **spsc** – SPSC to drop all previously acquired elements or do nothing

`spsc_consume`(spsc)

Consume an element from the spsc.

Parameters

- **spsc** – Spsc to consume from

Returns

Pointer to element or null if no consumable elements left

`spsc_release`(spsc)

Release a consumed element.

Parameters

- **spsc** – SPSC to release consumed element or do nothing

`spsc_release_all`(spsc)

Release all consumed elements.

Parameters

- **spsc** – SPSC to release consumed elements or do nothing

`spsc_acquirable`(spsc)

Count of acquirable in spsc.

Parameters

- **spsc** – SPSC to get item count for

`spsc_consumable`(spsc)
Count of consumables in spsc.

Parameters

- **spsc** – SPSC to get item count for

`spsc_peek`(spsc)
Peek at the first available item in queue.

Parameters

- **spsc** – Spsc to peek into

Returns
Pointer to element or null if no consumable elements left

`spsc_next`(spsc, item)
Peek at the next item in the queue from a given one.

Parameters

- **spsc** – SPSC to peek at
- **item** – Pointer to an item in the queue

Returns
Pointer to element or null if none left

`spsc_prev`(spsc, item)
Get the previous item in the queue from a given one.

Parameters

- **spsc** – SPSC to peek at
- **item** – Pointer to an item in the queue

Returns
Pointer to element or null if none left

struct **spsc**
Common SPSC attributes.

Warning

Not to be manipulated without the macros!

3.6 Executing Time Functions

The timing functions can be used to obtain execution time of a section of code to aid in analysis and optimization.

Please note that the timing functions may use a different timer than the default kernel timer, where the timer being used is specified by architecture, SoC or board configuration.

3.6.1 Configuration

To allow using the timing functions, `CONFIG_TIMING_FUNCTIONS` needs to be enabled.

3.6.2 Usage

To gather timing information:

1. Call *timing_init()* to initialize the timer.
2. Call *timing_start()* to signal the start of gathering of timing information. This usually starts the timer.
3. Call *timing_counter_get()* to mark the start of code execution.
4. Call *timing_counter_get()* to mark the end of code execution.
5. Call *timing_cycles_get()* to get the number of timer cycles between start and end of code execution.
6. Call *timing_cycles_to_ns()* with total number of cycles to convert number of cycles to nanoseconds.
7. Repeat from step 3 to gather timing information for other blocks of code.
8. Call *timing_stop()* to signal the end of gathering of timing information. This usually stops the timer.

Example

This shows an example on how to use the timing functions:

```
#include <zephyr/timing/timing.h>

void gather_timing(void)
{
    timing_t start_time, end_time;
    uint64_t total_cycles;
    uint64_t total_ns;

    timing_init();
    timing_start();

    start_time = timing_counter_get();

    code_execution_to_be_measured();

    end_time = timing_counter_get();

    total_cycles = timing_cycles_get(&start_time, &end_time);
    total_ns = timing_cycles_to_ns(total_cycles);

    timing_stop();
}
```

3.6.3 API documentation

group **timing_api**

Timing Measurement APIs.

The timing measurement APIs can be used to obtain execution time of a section of code to aid in analysis and optimization.

Please note that the timing functions may use a different timer than the default kernel timer, where the timer being used is specified by architecture, SoC or board configuration.

Functions

void **timing_init**(void)

Initialize the timing subsystem.

Perform the necessary steps to initialize the timing subsystem.

void **timing_start**(void)

Signal the start of the timing information gathering.

Signal to the timing subsystem that timing information will be gathered from this point forward.

void **timing_stop**(void)

Signal the end of the timing information gathering.

Signal to the timing subsystem that timing information is no longer being gathered from this point forward.

static inline timing_t **timing_counter_get**(void)

Return timing counter.

Returns
Timing counter.

static inline uint64_t **timing_cycles_get**(volatile timing_t *const start, volatile timing_t *const end)

Get number of cycles between `start` and `end`.

For some architectures or SoCs, the raw numbers from counter need to be scaled to obtain actual number of cycles.

Parameters

- **start** – Pointer to counter at start of a measured execution.
- **end** – Pointer to counter at stop of a measured execution.

Returns
Number of cycles between start and end.

static inline uint64_t **timing_freq_get**(void)

Get frequency of counter used (in Hz).

Returns
Frequency of counter used for timing in Hz.

static inline uint64_t **timing_cycles_to_ns**(uint64_t cycles)

Convert number of `cycles` into nanoseconds.

Parameters

- **cycles** – Number of cycles

Returns
Converted time value

static inline uint64_t **timing_cycles_to_ns_avg**(uint64_t cycles, uint32_t count)

Convert number of `cycles` into nanoseconds with averaging.

Parameters

- **cycles** – Number of cycles
- **count** – Times of accumulated cycles to average over

Returns
Converted time value

static inline uint32_t **timing_freq_get_mhz**(void)

Get frequency of counter used (in MHz).

Returns

Frequency of counter used for timing in MHz.

group **timing_api_arch**

Arch specific Timing Measurement APIs.

Implements the necessary bits to support timing measurement using architecture specific timing measurement mechanism.

Functions

void **arch_timing_init**(void)

Initialize the timing subsystem.

Perform the necessary steps to initialize the timing subsystem.

See also

timing_init()

void **arch_timing_start**(void)

Signal the start of the timing information gathering.

Signal to the timing subsystem that timing information will be gathered from this point forward.

See also

timing_start()

Note

Any call to *arch_timing_counter_get()* must be done between calls to *arch_timing_start()* and *arch_timing_stop()*, and on the same CPU core.

void **arch_timing_stop**(void)

Signal the end of the timing information gathering.

Signal to the timing subsystem that timing information is no longer being gathered from this point forward.

See also

timing_stop()

Note

Any call to *arch_timing_counter_get()* must be done between calls to *arch_timing_start()* and *arch_timing_stop()*, and on the same CPU core.

timing_t **arch_timing_counter_get**(void)

Return timing counter.

See also

timing_counter_get()

Note

Any call to *arch_timing_counter_get()* must be done between calls to *arch_timing_start()* and *arch_timing_stop()*, and on the same CPU core.

Note

Not all architectures have a timing counter with 64 bit precision. It is possible to see this value "go backwards" due to internal rollover. Timing code must be prepared to address the rollover (with platform-dependent code, e.g. by casting to a uint32_t before subtraction) or by using *arch_timing_cycles_get()* which is required to understand the distinction.

Returns

Timing counter.

uint64_t **arch_timing_cycles_get**(volatile timing_t *const start, volatile timing_t *const end)

Get number of cycles between `start` and `end`.

See also

timing_cycles_get()

Note

For some architectures, the raw numbers from counter need to be scaled to obtain actual number of cycles, or may roll over internally. This function computes a positive-definite interval between two returned cycle values.

Parameters

- **start** – Pointer to counter at start of a measured execution.
- **end** – Pointer to counter at stop of a measured execution.

Returns
Number of cycles between start and end.

uint64_t **arch_timing_freq_get**(void)
Get frequency of counter used (in Hz).

See also

timing_freq_get()

Returns
Frequency of counter used for timing in Hz.

uint64_t **arch_timing_cycles_to_ns**(uint64_t cycles)
Convert number of `cycles` into nanoseconds.

See also

timing_cycles_to_ns()

Parameters

- **cycles** – Number of cycles

Returns
Converted time value

uint64_t **arch_timing_cycles_to_ns_avg**(uint64_t cycles, uint32_t count)
Convert number of `cycles` into nanoseconds with averaging.

See also

timing_cycles_to_ns_avg()

Parameters

- **cycles** – Number of cycles
- **count** – Times of accumulated cycles to average over

Returns
Converted time value

uint32_t **arch_timing_freq_get_mhz**(void)
Get frequency of counter used (in MHz).

See also

timing_freq_get_mhz()

Returns
Frequency of counter used for timing in MHz.

group **timing_api_soc**
SoC specific Timing Measurement APIs.

Implements the necessary bits to support timing measurement using SoC specific timing measurement mechanism.

Functions

void **soc_timing_init**(void)
Initialize the timing subsystem on SoC.

Perform the necessary steps to initialize the timing subsystem.

See also

timing_init()

void **soc_timing_start**(void)
Signal the start of the timing information gathering.

Signal to the timing subsystem that timing information will be gathered from this point forward.

See also

timing_start()

void **soc_timing_stop**(void)
Signal the end of the timing information gathering.

Signal to the timing subsystem that timing information is no longer being gathered from this point forward.

See also

timing_stop()

timing_t **soc_timing_counter_get**(void)

Return timing counter.

See also

timing_counter_get()

Note

Not all SoCs have timing counters with 64 bit precision. It is possible to see this value "go backwards" due to internal rollover. Timing code must be prepared to address the rollover (with SoC dependent code, e.g. by casting to a uint32_t before subtraction) or by using *soc_timing_cycles_get()* which is required to understand the distinction.

Returns

Timing counter.

uint64_t **soc_timing_cycles_get**(volatile timing_t *const start, volatile timing_t *const end)

Get number of cycles between `start` and `end`.

See also

timing_cycles_get()

Note

The raw numbers from counter need to be scaled to obtain actual number of cycles, or may roll over internally. This function computes a positive-definite interval between two returned cycle values.

Parameters

- **start** – Pointer to counter at start of a measured execution.
- **end** – Pointer to counter at stop of a measured execution.

Returns

Number of cycles between start and end.

uint64_t **soc_timing_freq_get**(void)

Get frequency of counter used (in Hz).

See also

timing_freq_get()

Returns
Frequency of counter used for timing in Hz.

uint64_t **soc_timing_cycles_to_ns**(uint64_t cycles)
Convert number of `cycles` into nanoseconds.

See also

timing_cycles_to_ns()

Parameters

- **cycles** – Number of cycles

Returns
Converted time value

uint64_t **soc_timing_cycles_to_ns_avg**(uint64_t cycles, uint32_t count)
Convert number of `cycles` into nanoseconds with averaging.

See also

timing_cycles_to_ns_avg()

Parameters

- **cycles** – Number of cycles
- **count** – Times of accumulated cycles to average over

Returns
Converted time value

uint32_t **soc_timing_freq_get_mhz**(void)
Get frequency of counter used (in MHz).

See also

timing_freq_get_mhz()

Returns
Frequency of counter used for timing in MHz.

group `timing_api_board`

Board specific Timing Measurement APIs.

Implements the necessary bits to support timing measurement using board specific timing measurement mechanism.

Functions

void `board_timing_init`(void)

Initialize the timing subsystem.

Perform the necessary steps to initialize the timing subsystem.

See also

timing_init()

void `board_timing_start`(void)

Signal the start of the timing information gathering.

Signal to the timing subsystem that timing information will be gathered from this point forward.

See also

timing_start()

void `board_timing_stop`(void)

Signal the end of the timing information gathering.

Signal to the timing subsystem that timing information is no longer being gathered from this point forward.

See also

timing_stop()

timing_t `board_timing_counter_get`(void)

Return timing counter.

See also

timing_counter_get()

Note

Not all timing counters have 64 bit precision. It is possible to see this value "go backwards" due to internal rollover. Timing code must be prepared to address the rollover (with board dependent code, e.g. by casting to a uint32_t before subtraction) or by using *board_timing_cycles_get()* which is required to understand the distinction.

Returns
Timing counter.

uint64_t **board_timing_cycles_get**(volatile timing_t *const start, volatile timing_t *const end)

Get number of cycles between `start` and `end`.

See also

timing_cycles_get()

Note

The raw numbers from counter need to be scaled to obtain actual number of cycles, or may roll over internally. This function computes a positive-definite interval between two returned cycle values.

Parameters

- **start** – Pointer to counter at start of a measured execution.
- **end** – Pointer to counter at stop of a measured execution.

Returns
Number of cycles between start and end.

uint64_t **board_timing_freq_get**(void)

Get frequency of counter used (in Hz).

See also

timing_freq_get()

Returns
Frequency of counter used for timing in Hz.

uint64_t **board_timing_cycles_to_ns**(uint64_t cycles)

Convert number of `cycles` into nanoseconds.

See also

timing_cycles_to_ns()

Parameters

- `cycles` – Number of cycles

Returns
Converted time value

uint64_t `board_timing_cycles_to_ns_avg`(uint64_t cycles, uint32_t count)
Convert number of `cycles` into nanoseconds with averaging.

See also

timing_cycles_to_ns_avg()

Parameters

- `cycles` – Number of cycles
- `count` – Times of accumulated cycles to average over

Returns
Converted time value

uint32_t `board_timing_freq_get_mhz`(void)
Get frequency of counter used (in MHz).

See also

timing_freq_get_mhz()

Returns
Frequency of counter used for timing in MHz.

3.7 Object Cores

Object cores are a kernel debugging tool that can be used to both identify and perform operations on registered objects.

- *Object Core Concepts*
- *Object Core Statistics Concepts*
- *Implementation*
  - *Defining a New Object Type*
  - *Initializing a New Object Core*

  - *Walking a List of Object Cores*
  - *Object Core Statistics Querying*
- *Configuration Options*
- *API Reference*

3.7.1 Object Core Concepts

Each instance of an object embeds an object core field named *obj_core*. Objects of the same type are linked together via their respective object cores to form a singly linked list. Each object core also links to the their respective object type. Each object type contains a singly linked list linking together all the object cores of that type. Object types are also linked together via a singly linked list. Together, this can allow debugging tools to traverse all the objects in the system.

Object cores have been integrated into following kernel objects:

- *Condition Variables*
- *Events*
- *FIFOs* and *LIFOs*
- *Mailboxes*
- *Memory Slabs*
- *Message Queues*
- *Mutexes*
- *Pipes*
- *Semaphores*
- *Threads*
- *Timers*
- *System Memory Blocks*

Developers are free to integrate them if desired into other objects within their projects.

3.7.2 Object Core Statistics Concepts

A variety of kernel objects allow for the gathering and reporting of statistics. Object cores provide a uniform means to retrieve that information via object core statistics. When enabled, the object type contains a pointer to a statistics descriptor that defines the various operations that have been enabled for interfacing with the object's statistics. Additionally, the object core contains a pointer to the "raw" statistical information associated with that object. Raw data is the raw, unmanipulated data associated with the statistics. Queried data may be "raw", but it may also have been manipulated in some way by calculation (such as determining an average).

The following table indicates both what objects have been integrated into the object core statistics as well as the structures used for both "raw" and "queried" data.

Object	Raw Data Type	Query Data Type
struct mem_slab	struct mem_slab_info	struct sys_memory_stats
struct sys_mem_blocks	struct sys_mem_blocks_info	struct sys_memory_stats
struct k_thread	struct k_cycle_stats	struct k_thread_runtime_stats
struct _cpu	struct k_cycle_stats	struct k_thread_runtime_stats
struct z_kernel	struct k_cycle_stats[num CPUs]	struct k_thread_runtime_stats

3.7.3 Implementation

Defining a New Object Type

An object type is defined using a global variable of type *k_obj_type*. It must be initialized before any objects of that type are initialized. The following code shows how a new object type can be initialized for use with object cores and object core statistics.

```
/* Unique object type ID */

#define K_OBJ_TYPE_MY_NEW_TYPE  K_OBJ_TYPE_ID_GEN("UNIQ")
struct k_obj_type  my_obj_type;

struct my_obj_type_raw_info {
    ...
};

struct my_obj_type_query_stats {
    ...
};

struct my_new_obj {
    ...
    struct k_obj_core obj_core;
    struct my_obj_type_raw_info  info;
};

struct k_obj_core_stats_desc my_obj_type_stats_desc = {
    .raw_size = sizeof(struct my_obj_type_raw_stats),
    .query_size = sizeof(struct my_obj_type_query_stats),
    .raw = my_obj_type_stats_raw,
    .query = my_obj_type_stats_query,
    .reset = my_obj_type_stats_reset,
    .disable = NULL,    /* Stats gathering is always on */
    .enable = NULL,     /* Stats gathering is always on */
};

void my_obj_type_init(void)
{
    z_obj_type_init(&my_obj_type, K_OBJ_TYPE_MY_NEW_TYPE,
                    offsetof(struct my_new_obj, obj_core);
    k_obj_type_stats_init(&my_obj_type, &my_obj_type_stats_desc);
}
```

Initializing a New Object Core

Kernel objects that have already been integrated into the object core framework automatically have their object cores initialized when the object is initialized. However, developers that wish

to add their own objects into the framework need to both initialize the object core and link it. The following code builds on the example above and initializes the object core.

```
void my_new_obj_init(struct my_new_obj *new_obj)
{
    ...
    k_obj_core_init(K_OBJ_CORE(new_obj), &my_obj_type);
    k_obj_core_link(K_OBJ_CORE(new_obj));
    k_obj_core_stats_register(K_OBJ_CORE(new_obj), &new_obj->raw_stats,
                              sizeof(struct my_obj_type_raw_info));
}
```

Walking a List of Object Cores

Two routines exist for walking the list of object cores linked to an object type. These are *k_obj_type_walk_locked()* and *k_obj_type_walk_unlocked()*. The following code builds upon the example above and prints the addresses of all the objects of that new object type.

```
int walk_op(struct k_obj_core *obj_core, void *data)
{
    uint8_t *ptr;

    ptr = obj_core;
    ptr -= obj_core->type->obj_core_offset;

    printk("%p\n", ptr);

    return 0;
}

void print_object_addresses(void)
{
    struct k_obj_type *obj_type;

    /* Find the object type */

    obj_type = k_obj_type_find(K_OBJ_TYPE_MY_NEW_TYPE);

    /* Walk the list of objects */

    k_obj_type_walk_unlocked(obj_type, walk_op, NULL);
}
```

Object Core Statistics Querying

The following code builds on the examples above and shows how an object integrated into the object core statistics framework can both retrieve queried data and reset the stats associated with the object.

```
struct my_new_obj my_obj;

...

void my_func(void)
{
    struct my_obj_type_query_stats  my_stats;
    int  status;
```

(continues on next page)

(continued from previous page)

```
    my_obj_type_init(&my_obj);

    ...

    status = k_obj_core_stats_query(K_OBJ_CORE(&my_obj),
                                    &my_stats, sizeof(my_stats));
    if (status != 0) {
        /* Failed to get stats */
        ...
    } else {
        k_obj_core_stats_reset(K_OBJ_CORE(&my_obj));
    }

    ...
}
```

3.7.4 Configuration Options

Related configuration options:

- CONFIG_OBJ_CORE
- CONFIG_OBJ_CORE_CONDVAR
- CONFIG_OBJ_CORE_EVENT
- CONFIG_OBJ_CORE_FIFO
- CONFIG_OBJ_CORE_LIFO

- CONFIG_OBJ_CORE_STATS_SYSTEM
- CONFIG_OBJ_CORE_STATS_SYS_MEM_BLOCKS

3.7.5 API Reference

group `obj_core_apis`

Defines

K_OBJ_CORE(kobj)
: Convert kernel object pointer into its object core pointer.

K_OBJ_TYPE_ID_GEN(s)
: Generate new object type IDs based on a 4 letter string.

K_OBJ_TYPE_CONDVAR_ID
: Condition variable object type.

K_OBJ_TYPE_CPU_ID
: CPU object type.

K_OBJ_TYPE_EVENT_ID
: Event object type.

K_OBJ_TYPE_FIFO_ID
: FIFO object type.

K_OBJ_TYPE_KERNEL_ID
: Kernel object type.

K_OBJ_TYPE_LIFO_ID
: LIFO object type.

K_OBJ_TYPE_MEM_BLOCK_ID
: Memory block object type.

K_OBJ_TYPE_MBOX_ID
: Mailbox object type.

K_OBJ_TYPE_MEM_SLAB_ID
: Memory slab object type.

K_OBJ_TYPE_MSGQ_ID
: Message queue object type.

K_OBJ_TYPE_MUTEX_ID
: Mutex object type.

K_OBJ_TYPE_PIPE_ID
: Pipe object type.

K_OBJ_TYPE_SEM_ID
: Semaphore object type.

K_OBJ_TYPE_STACK_ID
: Stack object type.

`K_OBJ_TYPE_THREAD_ID`
: Thread object type.

`K_OBJ_TYPE_TIMER_ID`
: Timer object type.

Functions

struct *k_obj_type* *`k_obj_type_find`(uint32_t type_id)

Find a specific object type by ID.

Given an object type ID, this function searches for the object type that is associated with the specified type ID *type_id*.

Parameters

- `type_id` – Type ID associated with object type

Return values

- `NULL` – if object type not found
- `Pointer` – to object type if found

int `k_obj_type_walk_locked`(struct *k_obj_type* *type, int (*func)(struct *k_obj_core**, void*), void *data)

Walk the object type's list of object cores.

This function takes a global spinlock and walks the object type's list of object cores and invokes the callback function on each element while holding that lock. Although this will ensure that the list is not modified, one can expect a significant penalty in terms of performance and latency.

The callback function shall either return non-zero to stop further walking, or it shall return 0 to continue walking.

Parameters

- `type` – Pointer to the object type
- `func` – Callback to invoke on each object core of the object type
- `data` – Custom data passed to the callback

Return values

`non-zero` – if walk is terminated by the callback; otherwise 0

int `k_obj_type_walk_unlocked`(struct *k_obj_type* *type, int (*func)(struct *k_obj_core**, void*), void *data)

Walk the object type's list of object cores.

This function is similar to *k_obj_type_walk_locked()* except that it walks the list without obtaining the global spinlock. No synchronization is provided here. Mutation of the list of objects while this function is in progress must be prevented at the application layer, otherwise undefined/unreliable behavior, corruption and/or crashes may result.

The callback function shall either return non-zero to stop further walking, or it shall return 0 to continue walking.

Parameters

- `type` – Pointer to the object type
- `func` – Callback to invoke on each object core of the object type

- **data** – Custom data passed to the callback

Return values

non-zero – if walk is terminated by the callback; otherwise 0

void **k_obj_core_init**(struct *k_obj_core* *obj_core, struct *k_obj_type* *type)

Initialize the core of the kernel object.

Initializing the kernel object core associates it with the specified kernel object type.

Parameters

- **obj_core** – Pointer to the kernel object to initialize
- **type** – Pointer to the kernel object type

void **k_obj_core_link**(struct *k_obj_core* *obj_core)

Link the kernel object to the kernel object type list.

A kernel object can be optionally linked into the kernel object type's list of objects. A kernel object must have been initialized before it can be linked. Linked kernel objects can be traversed and have information extracted from them by system tools.

Parameters

- **obj_core** – Pointer to the kernel object

void **k_obj_core_init_and_link**(struct *k_obj_core* *obj_core, struct *k_obj_type* *type)

Automatically link the kernel object after initializing it.

A useful wrapper to both initialize the core of the kernel object and automatically link it into the kernel object type's list of objects.

Parameters

- **obj_core** – Pointer to the kernel object to initialize
- **type** – Pointer to the kernel object type

void **k_obj_core_unlink**(struct *k_obj_core* *obj_core)

Unlink the kernel object from the kernel object type list.

Kernel objects can be unlinked from their respective kernel object type lists. If on a list, it must be done at the end of the kernel object's life cycle.

Parameters

- **obj_core** – Pointer to the kernel object

struct **k_obj_core_stats_desc**

#include <obj_core.h> Object core statistics descriptor.

Public Members

size_t **raw_size**

Internal representation stats buffer size.

size_t **query_size**

Stats buffer size used for reporting.

int (***raw**)(struct *k_obj_core* *obj_core, void *stats)

Function pointer to retrieve internal representation of stats.

int (*query)(struct *k_obj_core* *obj_core, void *stats)
Function pointer to retrieve reported statistics.

int (*reset)(struct *k_obj_core* *obj_core)
Function pointer to reset object's statistics.

int (*disable)(struct *k_obj_core* *obj_core)
Function pointer to disable object's statistics gathering.

int (*enable)(struct *k_obj_core* *obj_core)
Function pointer to enable object's statistics gathering.

struct k_obj_type
#include <*obj_core.h*> Object type structure.

Public Members

sys_snode_t node
Node within list of object types.

sys_slist_t list
List of objects of this object type.

uint32_t id
Unique type ID.

size_t obj_core_offset
Offset to obj_core field.

struct k_obj_core
#include <*obj_core.h*> Object core structure.

Public Members

sys_snode_t node
Object node within object type's list.

struct *k_obj_type* *type
Object type to which object belongs.

group obj_core_stats_apis

Functions

int `k_obj_core_stats_register`(struct *k_obj_core* *obj_core, void *stats, size_t stats_len)

Register kernel object for gathering statistics.

Before a kernel object can gather statistics, it must be registered to do so. Registering will also automatically enable the kernel object to gather its statistics.

Parameters

- `obj_core` – Pointer to kernel object core
- `stats` – Pointer to raw kernel statistics
- `stats_len` – Size of raw kernel statistics buffer

Return values

- `0` – on success
- `-errno` – on failure

int `k_obj_core_stats_deregister`(struct *k_obj_core* *obj_core)

Deregister kernel object from gathering statistics.

Deregistering a kernel object core from gathering statistics prevents it from gathering any more statistics. It is expected to be invoked at the end of a kernel object's life cycle.

Parameters

- `obj_core` – Pointer to kernel object core

Return values

- `0` – on success
- `-errno` – on failure

int `k_obj_core_stats_raw`(struct *k_obj_core* *obj_core, void *stats, size_t stats_len)

Retrieve the raw statistics associated with the kernel object.

This function copies the raw statistics associated with the kernel object core specified by *obj_core* into the buffer *stats*. Note that the size of the buffer (*stats_len*) must match the size specified by the kernel object type's statistics descriptor.

Parameters

- `obj_core` – Pointer to kernel object core
- `stats` – Pointer to memory buffer into which to copy raw stats
- `stats_len` – Length of the memory buffer

Return values

- `0` – on success
- `-errno` – on failure

int `k_obj_core_stats_query`(struct *k_obj_core* *obj_core, void *stats, size_t stats_len)

Retrieve the statistics associated with the kernel object.

This function copies the statistics associated with the kernel object core specified by *obj_core* into the buffer *stats*. Unlike the raw statistics this may report calculated values such as averages. Note that the size of the buffer (*stats_len*) must match the size specified by the kernel object type's statistics descriptor.

Parameters

- `obj_core` – Pointer to kernel object core
- `stats` – Pointer to memory buffer into which to copy the queried stats
- `stats_len` – Length of the memory buffer

Return values

- `0` – on success
- `-errno` – on failure

int **k_obj_core_stats_reset**(struct *k_obj_core* *obj_core)

Reset the stats associated with the kernel object.

This function resets the statistics associated with the kernel object core specified by *obj_core*.

Parameters

- `obj_core` – Pointer to kernel object core

Return values

- `0` – on success
- `-errno` – on failure

int **k_obj_core_stats_disable**(struct *k_obj_core* *obj_core)

Stop gathering the stats associated with the kernel object.

This function temporarily stops the gathering of statistics associated with the kernel object core specified by *obj_core*. The gathering of statistics can be resumed by invoking :c:func :k_obj_core_stats_enable.

Parameters

- `obj_core` – Pointer to kernel object core

Return values

- `0` – on success
- `-errno` – on failure

int **k_obj_core_stats_enable**(struct *k_obj_core* *obj_core)

Reset the stats associated with the kernel object.

This function resumes the gathering of statistics associated with the kernel object core specified by *obj_core*.

Parameters

- `obj_core` – Pointer to kernel object core

Return values

- `0` – on success
- `-errno` – on failure

3.8 Time Utilities

3.8.1 Overview

Uptime in Zephyr is based on the a tick counter. With the default `CONFIG_TICKLESS_KERNEL` this counter advances at a nominally constant rate from zero at the instant the system started. The POSIX equivalent to this counter is something like `CLOCK_MONOTONIC` or, in Linux, `CLOCK_MONOTONIC_RAW`. *`k_uptime_get()`* provides a millisecond representation of this time.

Applications often need to correlate the Zephyr internal time with external time scales used in daily life, such as local time or Coordinated Universal Time. These systems interpret time

in different ways and may have discontinuities due to leap seconds and local time offsets like daylight saving time.

Because of these discontinuities, as well as significant inaccuracies in the clocks underlying the cycle counter, the offset between time estimated from the Zephyr clock and the actual time in a "real" civil time scale is not constant and can vary widely over the runtime of a Zephyr application.

The time utilities API supports:

- *converting between time representations*
- *synchronizing and aligning time scales*

For terminology and concepts that support these functions see *Concepts Underlying Time Support in Zephyr*.

3.8.2 Time Utility APIs

Representation Transformation

Time scale instants can be represented in multiple ways including:

- Seconds since an epoch. POSIX representations of time in this form include `time_t` and `struct timespec`, which are generally interpreted as a representation of "UNIX Time".
- Calendar time as a year, month, day, hour, minutes, and seconds relative to an epoch. POSIX representations of time in this form include `struct tm`.

Keep in mind that these are simply time representations that must be interpreted relative to a time scale which may be local time, UTC, or some other continuous or discontinuous scale.

Some necessary transformations are available in standard C library routines. For example, `time_t` measuring seconds since the POSIX EPOCH is converted to `struct tm` representing calendar time with gmtime(). Sub-second timestamps like `struct timespec` can also use this to produce the calendar time representation and deal with sub-second offsets separately.

The inverse transformation is not standardized: APIs like `mktime()` expect information about time zones. Zephyr provides this transformation with *`timeutil_timegm()`* and *`timeutil_timegm64()`*.

group **timeutil_repr_apis**

Functions

int64_t **timeutil_timegm64**(const struct *tm* *tm)

Convert broken-down time to a POSIX epoch offset in seconds.

See also

http://man7.org/linux/man-pages/man3/timegm.3.html

Parameters

- **tm** – pointer to broken down time.

Returns

the corresponding time in the POSIX epoch time scale.

time_t **timeutil_timegm**(const struct *tm* *tm)

Convert broken-down time to a POSIX epoch offset in seconds.

See also

http://man7.org/linux/man-pages/man3/timegm.3.html

Parameters

- **tm** – pointer to broken down time.

Returns

the corresponding time in the POSIX epoch time scale. If the time cannot be represented then (time_t)-1 is returned and `errno` is set to `ERANGE`.

Time Scale Synchronization

There are several factors that affect synchronizing time scales:

- The rate of discrete instant representation change. For example Zephyr uptime is tracked in ticks which advance at events that nominally occur at `CONFIG_SYS_CLOCK_TICKS_PER_SEC` Hertz, while an external time source may provide data in whole or fractional seconds (e.g. microseconds).
- The absolute offset required to align the two scales at a single instant.
- The relative error between observable instants in each scale, required to align multiple instants consistently. For example a reference clock that's conditioned by a 1-pulse-per-second GPS signal will be much more accurate than a Zephyr system clock driven by a RC oscillator with a +/- 250 ppm error.

Synchronization or alignment between time scales is done with a multi-step process:

- An instant in a time scale is represented by an (unsigned) 64-bit integer, assumed to advance at a fixed nominal rate.
- *timeutil_sync_config* records the nominal rates of a reference time scale/source (e.g. TAI) and a local time source (e.g. *k_uptime_ticks()*).
- *timeutil_sync_instant* records the representation of a single instant in both the reference and local time scales.
- *timeutil_sync_state* provides storage for an initial instant, a recently received second observation, and a skew that can adjust for relative errors in the actual rate of each time scale.
- *timeutil_sync_ref_from_local()* and *timeutil_sync_local_from_ref()* convert instants in one time scale to another taking into account skew that can be estimated from the two instances stored in the state structure by *timeutil_sync_estimate_skew()*.

group **timeutil_sync_apis**

Functions

int **timeutil_sync_state_update**(struct *timeutil_sync_state* *tsp, const struct *timeutil_sync_instant* *inst)

Record a new instant in the time synchronization state.

Note that this updates only the latest persisted instant. The skew is not adjusted automatically.

Parameters

- `tsp` – pointer to a *timeutil_sync_state* object.
- `inst` – the new instant to be recorded. This becomes the base instant if there is no base instant, otherwise the value must be strictly after the base instant in both the reference and local time scales.

Return values

- `0` – if installation succeeded in providing a new base
- `1` – if installation provided a new latest instant
- `-EINVAL` – if the new instant is not compatible with the base instant

int **timeutil_sync_state_set_skew**(struct *timeutil_sync_state* *tsp, float skew, const struct *timeutil_sync_instant* *base)

Update the state with a new skew and possibly base value.

Set the skew from a value retrieved from persistent storage, or calculated based on recent skew estimations including from *timeutil_sync_estimate_skew()*.

Optionally update the base timestamp. If the base is replaced the latest instant will be cleared until *timeutil_sync_state_update()* is invoked.

Parameters

- `tsp` – pointer to a time synchronization state.
- `skew` – the skew to be used. The value must be positive and shouldn't be too far away from 1.
- `base` – optional new base to be set. If provided this becomes the base timestamp that will be used along with skew to convert between reference and local timescale instants. Setting the base clears the captured latest value.

Returns
0 if skew was updated

Returns
-EINVAL if skew was not valid

float **timeutil_sync_estimate_skew**(const struct *timeutil_sync_state* *tsp)

Estimate the skew based on current state.

Using the base and latest syncpoints from the state determine the skew of the local clock relative to the reference clock. See *timeutil_sync_state::skew*.

Parameters

- `tsp` – pointer to a time synchronization state. The base and latest syncpoints must be present and the latest syncpoint must be after the base point in the local time scale.

Returns
the estimated skew, or zero if skew could not be estimated.

int **timeutil_sync_ref_from_local**(const struct *timeutil_sync_state* *tsp, uint64_t local, uint64_t *refp)

Interpolate a reference timescale instant from a local instant.

Parameters

- **tsp** – pointer to a time synchronization state. This must have a base and a skew installed.
- **local** – an instant measured in the local timescale. This may be before or after the base instant.
- **refp** – where the corresponding instant in the reference timescale should be stored. A negative interpolated reference time produces an error. If interpolation fails the referenced object is not modified.

Return values

- **0** – if interpolated using a skew of 1
- **1** – if interpolated using a skew not equal to 1
- **-EINVAL** –
  - the times synchronization state is not adequately initialized
  - refp is null
- **-ERANGE** – the interpolated reference time would be negative

int **timeutil_sync_local_from_ref**(const struct *timeutil_sync_state* *tsp, uint64_t ref, int64_t *localp)

Interpolate a local timescale instant from a reference instant.

Parameters

- **tsp** – pointer to a time synchronization state. This must have a base and a skew installed.
- **ref** – an instant measured in the reference timescale. This may be before or after the base instant.
- **localp** – where the corresponding instant in the local timescale should be stored. An interpolated value before local time 0 is provided without error. If interpolation fails the referenced object is not modified.

Return values

- **0** – if successful with a skew of 1
- **1** – if successful with a skew not equal to 1
- **-EINVAL** –
  - the time synchronization state is not adequately initialized
  - refp is null

int32_t **timeutil_sync_skew_to_ppb**(float skew)

Convert from a skew to an error in parts-per-billion.

A skew of 1.0 has zero error. A skew less than 1 has a positive error (clock is faster than it should be). A skew greater than one has a negative error (clock is slower than it should be).

Note that due to the limited precision of float compared with double the smallest error that can be represented is about 120 ppb. A “precise” time source may have error on the order of 2000 ppb.

A skew greater than 3.14748 may underflow the 32-bit representation; this represents a clock running at less than 1/3 its nominal rate.

Returns

skew error represented as parts-per-billion, or INT32_MIN if the skew cannot be represented in the return type.

struct **timeutil_sync_config**

#include <*timeutil.h*> Immutable state for synchronizing two clocks.

Values required to convert durations between two time scales.

> **Note**
>
> The accuracy of the translation and calculated skew between sources depends on the resolution of these frequencies. A reference frequency with microsecond or nanosecond resolution would produce the most accurate tracking when the local reference is the Zephyr tick counter. A reference source like an RTC chip with 1 Hz resolution requires a much larger interval between sampled instants to detect relative clock drift.

Public Members

uint32_t **ref_Hz**

The nominal instance counter rate in Hz.

This value is assumed to be precise, but may drift depending on the reference clock source.

The value must be positive.

uint32_t **local_Hz**

The nominal local counter rate in Hz.

This value is assumed to be inaccurate but reasonably stable. For a local clock driven by a crystal oscillator an error of 25 ppm is common; for an RC oscillator larger errors should be expected. The timeutil_sync infrastructure can calculate the skew between the local and reference clocks and apply it when converting between time scales.

The value must be positive.

struct **timeutil_sync_instant**

#include <*timeutil.h*> Representation of an instant in two time scales.

Capturing the same instant in two time scales provides a registration point that can be used to convert between those time scales.

Public Members

uint64_t **ref**

An instant in the reference time scale.

This must never be zero in an initialized *timeutil_sync_instant* object.

uint64_t **local**

The corresponding instance in the local time scale.

This may be zero in a valid *timeutil_sync_instant* object.

struct **timeutil_sync_state**

#include <timeutil.h> State required to convert instants between time scales.

This state in conjunction with functions that manipulate it capture the offset information necessary to convert between two timescales along with information that corrects for skew due to inaccuracies in clock rates.

State objects should be zero-initialized before use.

Public Members

const struct *timeutil_sync_config* ***cfg**

Pointer to reference and local rate information.

struct *timeutil_sync_instant* **base**

The base instant in both time scales.

struct *timeutil_sync_instant* **latest**

The most recent instant in both time scales.

This is captured here to provide data for skew calculation.

float **skew**

The scale factor used to correct for clock skew.

The nominal rate for the local counter is assumed to be inaccurate but stable, i.e. it will generally be some parts-per-million faster or slower than specified.

A duration in observed local clock ticks must be multiplied by this value to produce a duration in ticks of a clock operating at the nominal local rate.

A zero value indicates that the skew has not been initialized. If the value is zero when *base* is initialized the skew will be set to 1. Otherwise the skew is assigned through *timeutil_sync_state_set_skew()*.

3.8.3 Concepts Underlying Time Support in Zephyr

Terms from ISO/TC 154/WG 5 N0038 (ISO/WD 8601-1) and elsewhere:

- A *time axis* is a representation of time as an ordered sequence of instants.
- A *time scale* is a way of representing an instant relative to an origin that serves as the epoch.
- A time scale is *monotonic* (increasing) if the representation of successive time instants never decreases in value.
- A time scale is *continuous* if the representation has no abrupt changes in value, e.g. jumping forward or back when going between successive instants.
- Civil time generally refers to time scales that legally defined by civil authorities, like local governments, often to align local midnight to solar time.

Relevant Time Scales

International Atomic Time (TAI) is a time scale based on averaging clocks that count in SI seconds. TAI is a monotonic and continuous time scale.

Universal Time (UT) is a time scale based on Earth's rotation. UT is a discontinuous time scale as it requires occasional adjustments (leap seconds) to maintain alignment to changes in Earth's rotation. Thus the difference between TAI and UT varies over time. There are several variants of UT, with UTC being the most common.

UT times are independent of location. UT is the basis for Standard Time (or "local time") which is the time at a particular location. Standard time has a fixed offset from UT at any given instant, primarily influenced by longitude, but the offset may be adjusted ("daylight saving time") to align standard time to the local solar time. In a sense local time is "more discontinuous" than UT.

POSIX Time is a time scale that counts seconds since the "POSIX epoch" at 1970-01-01T00:00:00Z (i.e. the start of 1970 UTC). UNIX Time is an extension of POSIX time using negative values to represent times before the POSIX epoch. Both of these scales assume that every day has exactly 86400 seconds. In normal use instants in these scales correspond to times in the UTC scale, so they inherit the discontinuity.

The continuous analogue is UNIX Leap Time which is UNIX time plus all leap-second corrections added after the POSIX epoch (when TAI-UTC was 8 s).

Example of Time Scale Differences A positive leap second was introduced at the end of 2016, increasing the difference between TAI and UTC from 36 seconds to 37 seconds. There was no leap second introduced at the end of 1999, when the difference between TAI and UTC was only 32 seconds. The following table shows relevant civil and epoch times in several scales:

UTC Date	UNIX time	TAI Date	TAI-UTC	UNIX Leap Time
1970-01-01T00:00:00Z	0	1970-01-01T00:00:08	+8	0
1999-12-31T23:59:28Z	946684768	2000-01-01T00:00:00	+32	946684792
1999-12-31T23:59:59Z	946684799	2000-01-01T00:00:31	+32	946684823
2000-01-01T00:00:00Z	946684800	2000-01-01T00:00:32	+32	946684824
2016-12-31T23:59:59Z	1483228799	2017-01-01T00:00:35	+36	1483228827
2016-12-31T23:59:60Z	undefined	2017-01-01T00:00:36	+36	1483228828
2017-01-01T00:00:00Z	1483228800	2017-01-01T00:00:37	+37	1483228829

Functional Requirements The Zephyr tick counter has no concept of leap seconds or standard time offsets and is a continuous time scale. However it can be relatively inaccurate, with drifts as much as three minutes per hour (assuming an RC timer with 5% tolerance).

There are two stages required to support conversion between Zephyr time and common human time scales:

- Translation between the continuous but inaccurate Zephyr time scale and an accurate external stable time scale;
- Translation between the stable time scale and the (possibly discontinuous) civil time scale.

The API around *timeutil_sync_state_update()* supports the first step of converting between continuous time scales.

The second step requires external information including schedules of leap seconds and local time offset changes. This may be best provided by an external library, and is not currently part of the time utility APIs.

Selecting an External Source and Time Scale If an application requires civil time accuracy within several seconds then UTC could be used as the stable time source. However, if the external source adjusts to a leap second there will be a discontinuity: the elapsed time between two observations taken at 1 Hz is not equal to the numeric difference between their timestamps.

For precise activities a continuous scale that is independent of local and solar adjustments simplifies things considerably. Suitable continuous scales include:

- GPS time: epoch of 1980-01-06T00:00:00Z, continuous following TAI with an offset of TAI-GPS=19 s.
- Bluetooth Mesh time: epoch of 2000-01-01T00:00:00Z, continuous following TAI with an offset of -32.
- UNIX Leap Time: epoch of 1970-01-01T00:00:00Z, continuous following TAI with an offset of -8.

Because C and Zephyr library functions support conversion between integral and calendar time representations using the UNIX epoch, UNIX Leap Time is an ideal choice for the external time scale.

The mechanism used to populate synchronization points is not relevant: it may involve reading from a local high-precision RTC peripheral, exchanging packets over a network using a protocol like NTP or PTP, or processing NMEA messages received a GPS with or without a 1pps signal.

3.9 Utilities

This page contains reference documentation for <sys/util.h>, which provides miscellaneous utility functions and macros.

group sys-util

Since
2.4

Version
0.1.0

Defines

`POINTER_TO_UINT`(x)
Cast x, a pointer, to an unsigned integer.

`UINT_TO_POINTER`(x)
Cast x, an unsigned integer, to a `void*`.

`POINTER_TO_INT`(x)
Cast x, a pointer, to a signed integer.

`INT_TO_POINTER`(x)
Cast x, a signed integer, to a `void*`.

`BITS_PER_LONG`
Number of bits in a long int.

`BITS_PER_LONG_LONG`
Number of bits in a long long int.

`GENMASK`(h, l)
Create a contiguous bitmask starting at bit position `l` and ending at position `h`.

`GENMASK64`(h, l)
Create a contiguous 64-bit bitmask starting at bit position `l` and ending at position `h`.

LSB_GET(value)

Extract the Least Significant Bit from value.

FIELD_GET(mask, value)

Extract a bitfield element from value corresponding to the field mask mask.

FIELD_PREP(mask, value)

Prepare a bitfield element using value with mask representing its field position and width.

The result should be combined with other fields using a logical OR.

ZERO_OR_COMPILE_ERROR(cond)

0 if cond is true-ish; causes a compile error otherwise.

IS_ARRAY(array)

Zero if array has an array type, a compile error otherwise.

This macro is available only from C, not C++.

ARRAY_SIZE(array)

Number of elements in the given array.

In C++, due to language limitations, this will accept as array any type that implements operator[]. The results may not be particularly meaningful in this case.

In C, passing a pointer as array causes a compile error.

IS_ARRAY_ELEMENT(array, ptr)

Whether ptr is an element of array.

This macro can be seen as a slightly stricter version of *PART_OF_ARRAY* in that it also ensures that ptr is aligned to an array-element boundary of array.

In C, passing a pointer as array causes a compile error.

Parameters

- **array** – the array in question
- **ptr** – the pointer to check

Returns

1 if ptr is part of array, 0 otherwise

ARRAY_INDEX(array, ptr)

Index of ptr within array.

With CONFIG_ASSERT=y, this macro will trigger a runtime assertion when ptr does not fall into the range of array or when ptr is not aligned to an array-element boundary of array.

In C, passing a pointer as array causes a compile error.

Parameters

- **array** – the array in question
- **ptr** – pointer to an element of array

Returns

the array index of ptr within array, on success

PART_OF_ARRAY(array, ptr)

Check if a pointer ptr lies within array.

In C but not C++, this causes a compile error if array is not an array (e.g. if ptr and array are mixed up).

Parameters

- **array** – an array
- **ptr** – a pointer

Returns
1 if ptr is part of array, 0 otherwise

ARRAY_INDEX_FLOOR(array, ptr)

Array-index of ptr within array, rounded down.

This macro behaves much like *ARRAY_INDEX* with the notable difference that it accepts any ptr in the range of array rather than exclusively a ptr aligned to an array-element boundary of array.

With CONFIG_ASSERT=y, this macro will trigger a runtime assertion when ptr does not fall into the range of array.

In C, passing a pointer as array causes a compile error.

Parameters

- **array** – the array in question
- **ptr** – pointer to an element of array

Returns
the array index of ptr within array, on success

ARRAY_FOR_EACH(array, idx)

Iterate over members of an array using an index variable.

Parameters

- **array** – the array in question
- **idx** – name of array index variable

ARRAY_FOR_EACH_PTR(array, ptr)

Iterate over members of an array using a pointer.

Parameters

- **array** – the array in question
- **ptr** – pointer to an element of array

SAME_TYPE(a, b)

Validate if two entities have a compatible type.

Parameters

- **a** – the first entity to be compared
- **b** – the second entity to be compared

Returns
1 if the two elements are compatible, 0 if they are not

CONTAINER_OF_VALIDATE(ptr, type, field)

Validate CONTAINER_OF parameters, only applies to C mode.

CONTAINER_OF(ptr, type, field)

Get a pointer to a structure containing the element.

Example:

```
struct foo {
   int bar;
};

struct foo my_foo;
int *ptr = &my_foo.bar;

struct foo *container = CONTAINER_OF(ptr, struct foo, bar);
```

Above, `container` points at `my_foo`.

Parameters

- **ptr** – pointer to a structure element
- **type** – name of the type that `ptr` is an element of
- **field** – the name of the field within the struct `ptr` points to

Returns
a pointer to the structure that contains `ptr`

`SIZEOF_FIELD`(type, member)

Report the size of a struct field in bytes.

Parameters

- **type** – The structure containing the field of interest.
- **member** – The field to return the size of.

Returns
The field size.

`CONCAT`(...)

Concatenate input arguments.

Concatenate provided tokens into a combined token during the preprocessor pass. This can be used to, for ex., build an identifier out of multiple parts, where one of those parts may be, for ex, a number, another macro, or a macro argument.

Parameters

- `...` – Tokens to concatencate

Returns
Concatenated token.

`IS_ALIGNED`(ptr, align)

Check if `ptr` is aligned to `align` alignment.

`ROUND_UP`(x, align)

Value of `x` rounded up to the next multiple of `align`.

`ROUND_DOWN`(x, align)

Value of `x` rounded down to the previous multiple of `align`.

`WB_UP`(x)

Value of `x` rounded up to the next word boundary.

`WB_DN`(x)

Value of `x` rounded down to the previous word boundary.

`DIV_ROUND_UP`(n, d)

Divide and round up.

Example:

```
DIV_ROUND_UP(1, 2); // 1
DIV_ROUND_UP(3, 2); // 2
```

Parameters

- **n** – Numerator.
- **d** – Denominator.

Returns
The result of n / d, rounded up.

`DIV_ROUND_CLOSEST`(n, d)

Divide and round to the nearest integer.

Example:

```
DIV_ROUND_CLOSEST(5, 2); // 3
DIV_ROUND_CLOSEST(5, -2); // -3
DIV_ROUND_CLOSEST(5, 3); // 2
```

Parameters

- **n** – Numerator.
- **d** – Denominator.

Returns
The result of n / d, rounded to the nearest integer.

`ceiling_fraction`(numerator, divider)

Ceiling function applied to `numerator` / `divider` as a fraction.

Deprecated:
Use *DIV_ROUND_UP()* instead.

`MAX`(a, b)

Obtain the maximum of two values.

Note

Arguments are evaluated twice. Use Z_MAX for a GCC-only, single evaluation version

Parameters

- **a** – First value.
- **b** – Second value.

Returns
Maximum value of a and b.

`MIN`(a, b)

Obtain the minimum of two values.

> **Note**
>
> Arguments are evaluated twice. Use Z_MIN for a GCC-only, single evaluation version

Parameters

- `a` – First value.
- `b` – Second value.

Returns
Minimum value of a and b.

`CLAMP`(val, low, high)

Clamp a value to a given range.

> **Note**
>
> Arguments are evaluated multiple times. Use Z_CLAMP for a GCC-only, single evaluation version.

Parameters

- `val` – Value to be clamped.
- `low` – Lowest allowed value (inclusive).
- `high` – Highest allowed value (inclusive).

Returns
Clamped value.

`IN_RANGE`(val, min, max)

Checks if a value is within range.

> **Note**
>
> `val` is evaluated twice.

Parameters

- `val` – Value to be checked.
- `min` – Lower bound (inclusive).
- `max` – Upper bound (inclusive).

Return values

- `true` – If value is within range
- `false` – If the value is not within range

`LOG2`(x)

Compute log2(x)

> **Note**
>
> This macro expands its argument multiple times (to permit use in constant expressions), which must not have side effects.

Parameters

- x – An unsigned integral value to compute logarithm of (positive only)

Returns

log2(x) when 1 <= x <= max(x), -1 when x < 1

`LOG2CEIL(x)`

Compute ceil(log2(x))

> **Note**
>
> This macro expands its argument multiple times (to permit use in constant expressions), which must not have side effects.

Parameters

- x – An unsigned integral value

Returns

ceil(log2(x)) when 1 <= x <= max(type(x)), 0 when x < 1

`NHPOT(x)`

Compute next highest power of two.

Equivalent to 2^ceil(log2(x))

> **Note**
>
> This macro expands its argument multiple times (to permit use in constant expressions), which must not have side effects.

Parameters

- x – An unsigned integral value

Returns

2^ceil(log2(x)) or 0 if 2^ceil(log2(x)) would saturate 64-bits

`KB(x)`

Number of bytes in x kibibytes.

`MB(x)`

Number of bytes in x mebibytes.

`GB(x)`

Number of bytes in x gibibytes.

`KHZ(x)`

Number of Hz in x kHz.

`MHZ(x)`

Number of Hz in x MHz.

WAIT_FOR(expr, timeout, delay_stmt)

Wait for an expression to return true with a timeout.

Spin on an expression with a timeout and optional delay between iterations

Commonly needed when waiting on hardware to complete an asynchronous request to read/write/initialize/reset, but useful for any expression.

Parameters

- **expr** – Truth expression upon which to poll, e.g.: XYZREG & XYZREG_EN
- **timeout** – Timeout to wait for in microseconds, e.g.: 1000 (1ms)
- **delay_stmt** – Delay statement to perform each poll iteration e.g.: NULL, *k_yield()*, k_msleep(1) or k_busy_wait(1)

Return values

expr – As a boolean return, if false then it has timed out.

BIT(n)

Unsigned integer with bit position n set (signed in assembly language).

BIT64(_n)

64-bit unsigned integer with bit position _n set.

WRITE_BIT(var, bit, set)

Set or clear a bit depending on a boolean value.

The argument var is a variable whose value is written to as a side effect.

Parameters

- **var** – Variable to be altered
- **bit** – Bit number
- **set** – if 0, clears bit in var; any other value sets bit

BIT_MASK(n)

Bit mask with bits 0 through n-1 (inclusive) set, or 0 if n is 0.

BIT64_MASK(n)

64-bit bit mask with bits 0 through n-1 (inclusive) set, or 0 if n is 0.

IS_POWER_OF_TWO(x)

Check if a x is a power of two.

IS_SHIFTED_BIT_MASK(m, s)

Check if bits are set continuously from the specified bit.

The macro is not dependent on the bit-width.

Parameters

- **m** – Check whether the bits are set continuously or not.
- **s** – Specify the lowest bit for that is continuously set bits.

IS_BIT_MASK(m)

Check if bits are set continuously from the LSB.

Parameters

- **m** – Check whether the bits are set continuously from LSB.

IS_ENABLED(config_macro)

Check for macro definition in compiler-visible expressions.

This trick was pioneered in Linux as the config_enabled() macro. It has the effect of taking a macro value that may be defined to "1" or may not be defined at all and turning it into a literal expression that can be handled by the C compiler instead of just the preprocessor. It is often used with a CONFIG_FOO macro which may be defined to 1 via Kconfig, or left undefined.

That is, it works similarly to `#if defined(CONFIG_FOO)` except that its expansion is a C expression. Thus, much `#ifdef` usage can be replaced with equivalents like:

```
if (IS_ENABLED(CONFIG_FOO)) {
        do_something_with_foo
}
```

This is cleaner since the compiler can generate errors and warnings for `do_something_with_foo` even when CONFIG_FOO is undefined.

Note: Use of IS_ENABLED in a `#if` statement is discouraged as it doesn't provide any benefit vs plain `#if defined()`

Parameters

- **config_macro** – Macro to check

Returns

1 if `config_macro` is defined to 1, 0 otherwise (including if `config_macro` is not defined)

COND_CODE_1(_flag, _if_1_code, _else_code)

Insert code depending on whether `_flag` expands to 1 or not.

This relies on similar tricks as *IS_ENABLED()*, but as the result of `_flag` expansion, results in either `_if_1_code` or `_else_code` is expanded.

To prevent the preprocessor from treating commas as argument separators, the `_if_1_code` and `_else_code` expressions must be inside brackets/parentheses: `()`. These are stripped away during macro expansion.

Example:

```
COND_CODE_1(CONFIG_FLAG, (uint32_t x;), (there_is_no_flag();))
```

If CONFIG_FLAG is defined to 1, this expands to:

```
uint32_t x;
```

It expands to `there_is_no_flag();` otherwise.

This could be used as an alternative to:

```
#if defined(CONFIG_FLAG) && (CONFIG_FLAG == 1)
#define MAYBE_DECLARE(x) uint32_t x
#else
#define MAYBE_DECLARE(x) there_is_no_flag()
#endif

MAYBE_DECLARE(x);
```

However, the advantage of *COND_CODE_1()* is that code is resolved in place where it is used, while the `#if` method defines MAYBE_DECLARE on two lines and requires it to be invoked again on a separate line. This makes *COND_CODE_1()* more concise and also sometimes more useful when used within another macro's expansion.

Note

_flag can be the result of preprocessor expansion, e.g. an expression involving *NUM_VA_ARGS_LESS_1(...)*. However, _if_1_code is only expanded if _flag expands to the integer literal 1. Integer expressions that evaluate to 1, e.g. after doing some arithmetic, will not work.

Parameters

- **_flag** – evaluated flag
- **_if_1_code** – result if _flag expands to 1; must be in parentheses
- **_else_code** – result otherwise; must be in parentheses

COND_CODE_0(_flag, _if_0_code, _else_code)

Like *COND_CODE_1()* except tests if _flag is 0.

This is like *COND_CODE_1()*, except that it tests whether _flag expands to the integer literal 0. It expands to _if_0_code if so, and _else_code otherwise; both of these must be enclosed in parentheses.

See also

COND_CODE_1()

Parameters

- **_flag** – evaluated flag
- **_if_0_code** – result if _flag expands to 0; must be in parentheses
- **_else_code** – result otherwise; must be in parentheses

IF_ENABLED(_flag, _code)

Insert code if _flag is defined and equals 1.

Like *COND_CODE_1()*, this expands to _code if _flag is defined to 1; it expands to nothing otherwise.

Example:

```
IF_ENABLED(CONFIG_FLAG, (uint32_t foo;))
```

If CONFIG_FLAG is defined to 1, this expands to:

```
uint32_t foo;
```

and to nothing otherwise.

It can be considered as a more compact alternative to:

```
#if defined(CONFIG_FLAG) && (CONFIG_FLAG == 1)
uint32_t foo;
#endif
```

Parameters

- **_flag** – evaluated flag
- **_code** – result if _flag expands to 1; must be in parentheses

IF_DISABLED(_flag, _code)

Insert code if _flag is not defined as 1.

This expands to nothing if _flag is defined and equal to 1; it expands to _code otherwise.

Example:

```
IF_DISABLED(CONFIG_FLAG, (uint32_t foo;))
```

If CONFIG_FLAG isn't defined or different than 1, this expands to:

```
uint32_t foo;
```

and to nothing otherwise.

IF_DISABLED does the opposite of IF_ENABLED.

Parameters

- **_flag** – evaluated flag
- **_code** – result if _flag does not expand to 1; must be in parentheses

IS_EMPTY(...)

Check if a macro has a replacement expression.

If a is a macro defined to a nonempty value, this will return true, otherwise it will return false. It only works with defined macros, so an additional #ifdef test may be needed in some cases.

This macro may be used with *COND_CODE_1()* and *COND_CODE_0()* while processing __VA_ARGS__ to avoid processing empty arguments.

Example:

```
#define EMPTY
#define NON_EMPTY  1
#undef  UNDEFINED
IS_EMPTY(EMPTY)
IS_EMPTY(NON_EMPTY)
IS_EMPTY(UNDEFINED)
#if defined(EMPTY) && IS_EMPTY(EMPTY) == true
some_conditional_code
#endif
```

In above examples, the invocations of *IS_EMPTY(...)* return true, false, and true; some_conditional_code is included.

Parameters

- ... – macro to check for emptiness (may be __VA_ARGS__)

IS_EQ(a, b)

Like a == b, but does evaluation and short-circuiting at C preprocessor time.

This however only works for integer literal from 0 to 4095.

LIST_DROP_EMPTY(...)

Remove empty arguments from list.

During macro expansion, __VA_ARGS__ and other preprocessor generated lists may contain empty elements, e.g.:

```
#define LIST ,a,b,,d,
```

Using EMPTY to show each empty element, LIST contains:

```
EMPTY, a, b, EMPTY, d
```

When processing such lists, e.g. using *FOR_EACH()*, all empty elements will be processed, and may require filtering out. To make that process easier, it is enough to invoke LIST_DROP_EMPTY which will remove all empty elements.

Example:

```
LIST_DROP_EMPTY(LIST)
```

expands to:

```
a, b, d
```

Parameters

- ... – list to be processed

EMPTY

Macro with an empty expansion.

This trivial definition is provided for readability when a macro should expand to an empty result, which e.g. is sometimes needed to silence checkpatch.

Example:

```
#define LIST_ITEM(n) , item##n
```

The above would cause checkpatch to complain, but:

```
#define LIST_ITEM(n) EMPTY, item##n
```

would not.

IDENTITY(V)

Macro that expands to its argument.

This is useful in macros like *FOR_EACH()* when there is no transformation required on the list elements.

Parameters

- V – any value

GET_ARG_N(N, ...)

Get nth argument from argument list.

Parameters

- N – Argument index to fetch. Counter from 1.
- ... – Variable list of arguments from which one argument is returned.

Returns

Nth argument.

GET_ARGS_LESS_N(N, ...)

Strips n first arguments from the argument list.

Parameters

- N – Number of arguments to discard.
- ... – Variable list of arguments.

Returns
argument list without N first arguments.

`UTIL_OR`(a, b)

Like `a || b`, but does evaluation and short-circuiting at C preprocessor time.

This is not the same as the binary `||` operator; in particular, `a` should expand to an integer literal 0 or 1. However, `b` can be any value.

This can be useful when `b` is an expression that would cause a build error when `a` is 1.

`UTIL_AND`(a, b)

Like `a && b`, but does evaluation and short-circuiting at C preprocessor time.

This is not the same as the binary `&&`, however; in particular, `a` should expand to an integer literal 0 or 1. However, `b` can be any value.

This can be useful when `b` is an expression that would cause a build error when `a` is 0.

`UTIL_INC`(x)

UTIL_INC(x) for an integer literal x from 0 to 4095 expands to an integer literal whose value is x+1.

See also

UTIL_DEC(x)

`UTIL_DEC`(x)

UTIL_DEC(x) for an integer literal x from 0 to 4095 expands to an integer literal whose value is x-1.

See also

UTIL_INC(x)

`UTIL_X2`(y)

UTIL_X2(y) for an integer literal y from 0 to 4095 expands to an integer literal whose value is 2y.

`LISTIFY`(LEN, F, sep, ...)

Generates a sequence of code with configurable separator.

Example:

```
#define FOO(i, _) MY_PWM ## i
{ LISTIFY(PWM_COUNT, FOO, (,)) }
```

The above two lines expand to:

{ MY_PWM0 , MY_PWM1 }

Note

Calling LISTIFY with undefined arguments has undefined behavior.

Parameters

- **LEN** – The length of the sequence. Must be an integer literal less than 4095.
- **F** – A macro function that accepts at least two arguments: `F(i, ...)`. `F` is called repeatedly in the expansion. Its first argument `i` is the index in the sequence, and the variable list of arguments passed to LISTIFY are passed through to `F`.
- **sep** – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.

FOR_EACH(F, sep, ...)

Call a macro `F` on each provided argument with a given separator between each call.

Example:

```
#define F(x) int a##x
FOR_EACH(F, (;), 4, 5, 6);
```

This expands to:

```
int a4;
int a5;
int a6;
```

Parameters

- **F** – Macro to invoke
- **sep** – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
- `...` – Variable argument list. The macro `F` is invoked as `F(element)` for each element in the list.

FOR_EACH_NONEMPTY_TERM(F, term, ...)

Like *FOR_EACH()*, but with a terminator instead of a separator, and drops empty elements from the argument list.

The `sep` argument to *FOR_EACH(F, (sep), a, b)* is a separator which is placed between calls to `F`, like this:

```
FOR_EACH(F, (sep), a, b) // F(a) sep F(b)
                         //              ^^^ no sep here!
```

By contrast, the `term` argument to *FOR_EACH_NONEMPTY_TERM(F, (term),a, b)* is added after each time `F` appears in the expansion:

```
FOR_EACH_NONEMPTY_TERM(F, (term), a, b) // F(a) term F(b) term
                                        //               ^^^^
```

Further, any empty elements are dropped:

```
FOR_EACH_NONEMPTY_TERM(F, (term), a, EMPTY, b) // F(a) term F(b) term
```

This is more convenient in some cases, because *FOR_EACH_NONEMPTY_TERM()* expands to nothing when given an empty argument list, and it's often cumbersome to write a macro `F` that does the right thing even when given an empty argument.

One example is when `__VA_ARGS__` may or may not be empty, and the results are embedded in a larger initializer:

```
#define SQUARE(x) ((x)*(x))

int my_array[] = {
        FOR_EACH_NONEMPTY_TERM(SQUARE, (,), FOO(...))
        FOR_EACH_NONEMPTY_TERM(SQUARE, (,), BAR(...))
        FOR_EACH_NONEMPTY_TERM(SQUARE, (,), BAZ(...))
};
```

This is more convenient than:

a. figuring out whether the FOO, BAR, and BAZ expansions are empty and adding a comma manually (or not) between *FOR_EACH()* calls

b. rewriting SQUARE so it reacts appropriately when "x" is empty (which would be necessary if e.g. FOO expands to nothing)

Parameters

- **F** – Macro to invoke on each nonempty element of the variable arguments
- **term** – Terminator (e.g. comma or semicolon) placed after each invocation of F. Must be in parentheses; this is required to enable providing a comma as separator.
- `...` – Variable argument list. The macro F is invoked as `F(element)` for each nonempty element in the list.

`FOR_EACH_IDX`(F, sep, ...)

Call macro F on each provided argument, with the argument's index as an additional parameter.

This is like *FOR_EACH()*, except F should be a macro which takes two arguments: `F(index, variable_arg)`.

Example:

```
#define F(idx, x) int a##idx = x
FOR_EACH_IDX(F, (;), 4, 5, 6);
```

This expands to:

```
int a0 = 4;
int a1 = 5;
int a2 = 6;
```

Parameters

- **F** – Macro to invoke
- **sep** – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
- `...` – Variable argument list. The macro F is invoked as `F(index, element)` for each element in the list.

`FOR_EACH_FIXED_ARG`(F, sep, fixed_arg, ...)

Call macro F on each provided argument, with an additional fixed argument as a parameter.

This is like *FOR_EACH()*, except F should be a macro which takes two arguments: `F(variable_arg, fixed_arg)`.

Example:

```
static void func(int val, void *dev);
FOR_EACH_FIXED_ARG(func, (;), dev, 4, 5, 6);
```

This expands to:

```
func(4, dev);
func(5, dev);
func(6, dev);
```

Parameters

- **F** – Macro to invoke
- **sep** – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
- **fixed_arg** – Fixed argument passed to `F` as the second macro parameter.
- `...` – Variable argument list. The macro `F` is invoked as `F(element, fixed_arg)` for each element in the list.

`FOR_EACH_IDX_FIXED_ARG`(F, sep, fixed_arg, ...)

Calls macro `F` for each variable argument with an index and fixed argument.

This is like the combination of *FOR_EACH_IDX()* with *FOR_EACH_FIXED_ARG()*.

Example:

```
#define F(idx, x, fixed_arg) int fixed_arg##idx = x
FOR_EACH_IDX_FIXED_ARG(F, (;), a, 4, 5, 6);
```

This expands to:

```
int a0 = 4;
int a1 = 5;
int a2 = 6;
```

Parameters

- **F** – Macro to invoke
- **sep** – Separator (e.g. comma or semicolon). Must be in parentheses; This is required to enable providing a comma as separator.
- **fixed_arg** – Fixed argument passed to `F` as the third macro parameter.
- `...` – Variable list of arguments. The macro `F` is invoked as `F(index, element, fixed_arg)` for each element in the list.

`REVERSE_ARGS`(...)

Reverse arguments order.

Parameters

- `...` – Variable argument list.

`NUM_VA_ARGS_LESS_1`(...)

Number of arguments in the variable arguments list minus one.

Note

Supports up to 64 arguments.

Parameters

- ... – List of arguments

Returns
Number of variadic arguments in the argument list, minus one

NUM_VA_ARGS(...)

Number of arguments in the variable arguments list.

> **Note**
> Supports up to 63 arguments.

Parameters

- ... – List of arguments

Returns
Number of variadic arguments in the argument list

MACRO_MAP_CAT(...)

Mapping macro that pastes results together.

This is similar to *FOR_EACH()* in that it invokes a macro repeatedly on each element of __VA_ARGS__. However, unlike *FOR_EACH()*, *MACRO_MAP_CAT()* pastes the results together into a single token.

For example, with this macro FOO:

```
#define FOO(x) item_##x##_
```

MACRO_MAP_CAT(FOO, a, b, c), expands to the token:

```
item_a_item_b_item_c_
```

Parameters

- ... – Macro to expand on each argument, followed by its arguments. (The macro should take exactly one argument.)

Returns
The results of expanding the macro on each argument, all pasted together

MACRO_MAP_CAT_N(N, ...)

Mapping macro that pastes a fixed number of results together.

Similar to *MACRO_MAP_CAT()*, but expects a fixed number of arguments. If more arguments are given than are expected, the rest are ignored.

Parameters

- N – Number of arguments to map
- ... – Macro to expand on each argument, followed by its arguments. (The macro should take exactly one argument.)

Returns
The results of expanding the macro on each argument, all pasted together

Functions

static inline bool **is_power_of_two**(unsigned int x)

Is x a power of two?

Parameters

- **x** – value to check

Returns
true if x is a power of two, false otherwise

ALWAYS_INLINE static bool **is_null_no_warn**(void *p)

Is p equal to NULL?

Some macros may need to check their arguments against NULL to support multiple use-cases, but NULL checks can generate warnings if such a macro is used in contexts where that particular argument can never be NULL.

The warnings can be triggered if: a) all macros are expanded (e.g. when using CONFIG_COMPILER_SAVE_TEMPS=y) or b) tracking of macro expansions are turned off (-ftrack-macro-expansion=0)

The warnings can be circumvented by using this inline function for doing the NULL check within the macro. The compiler is still able to optimize the NULL check out at a later stage.

Parameters

- **p** – Pointer to check

Returns
true if p is equal to NULL, false otherwise

static inline int64_t **arithmetic_shift_right**(int64_t value, uint8_t shift)

Arithmetic shift right.

Parameters

- **value** – value to shift
- **shift** – number of bits to shift

Returns
value shifted right by shift; opened bit positions are filled with the sign bit

static inline void **bytecpy**(void *dst, const void *src, size_t size)

byte by byte memcpy.

Copy size bytes of src into dest. This is guaranteed to be done byte by byte.

Parameters

- **dst** – Pointer to the destination memory.
- **src** – Pointer to the source of the data.
- **size** – The number of bytes to copy.

static inline void **byteswp**(void *a, void *b, size_t size)

byte by byte swap.

Swap *size* bytes between memory regions *a* and *b*. This is guaranteed to be done byte by byte.

Parameters

- **a** – Pointer to the first memory region.

- **b** – Pointer to the second memory region.
- **size** – The number of bytes to swap.

int **char2hex**(char c, uint8_t *x)

Convert a single character into a hexadecimal nibble.

Parameters

- **c** – The character to convert
- **x** – The address of storage for the converted number.

Returns

Zero on success or (negative) error code otherwise.

int **hex2char**(uint8_t x, char *c)

Convert a single hexadecimal nibble into a character.

Parameters

- **c** – The number to convert
- **x** – The address of storage for the converted character.

Returns

Zero on success or (negative) error code otherwise.

size_t **bin2hex**(const uint8_t *buf, size_t buflen, char *hex, size_t hexlen)

Convert a binary array into string representation.

Parameters

- **buf** – The binary array to convert
- **buflen** – The length of the binary array to convert
- **hex** – Address of where to store the string representation.
- **hexlen** – Size of the storage area for string representation.

Returns

The length of the converted string, or 0 if an error occurred.

size_t **hex2bin**(const char *hex, size_t hexlen, uint8_t *buf, size_t buflen)

Convert a hexadecimal string into a binary array.

Parameters

- **hex** – The hexadecimal string to convert
- **hexlen** – The length of the hexadecimal string to convert.
- **buf** – Address of where to store the binary data
- **buflen** – Size of the storage area for binary data

Returns

The length of the binary array, or 0 if an error occurred.

static inline uint8_t **bcd2bin**(uint8_t bcd)

Convert a binary coded decimal (BCD 8421) value to binary.

Parameters

- **bcd** – BCD 8421 value to convert.

Returns

Binary representation of input value.

static inline uint8_t **bin2bcd**(uint8_t bin)

Convert a binary value to binary coded decimal (BCD 8421).

Parameters

- **bin** – Binary value to convert.

Returns
BCD 8421 representation of input value.

uint8_t **u8_to_dec**(char *buf, uint8_t buflen, uint8_t value)

Convert a uint8_t into a decimal string representation.

Convert a uint8_t value into its ASCII decimal string representation. The string is terminated if there is enough space in buf.

Parameters

- **buf** – Address of where to store the string representation.
- **buflen** – Size of the storage area for string representation.
- **value** – The value to convert to decimal string

Returns
The length of the converted string (excluding terminator if any), or 0 if an error occurred.

static inline int32_t **sign_extend**(uint32_t value, uint8_t index)

Sign extend an 8, 16 or 32 bit value using the index bit as sign bit.

Parameters

- **value** – The value to sign expand.
- **index** – 0 based bit index to sign bit (0 to 31)

static inline int64_t **sign_extend_64**(uint64_t value, uint8_t index)

Sign extend a 64 bit value using the index bit as sign bit.

Parameters

- **value** – The value to sign expand.
- **index** – 0 based bit index to sign bit (0 to 63)

char ***utf8_trunc**(char *utf8_str)

Properly truncate a NULL-terminated UTF-8 string.

Take a NULL-terminated UTF-8 string and ensure that if the string has been truncated (by setting the NULL terminator) earlier by other means, that the string ends with a properly formatted UTF-8 character (1-4 bytes).

Parameters

- **utf8_str** – NULL-terminated string

Returns
Pointer to the `utf8_str`

char ***utf8_lcpy**(char *dst, const char *src, size_t n)

Copies a UTF-8 encoded string from `src` to `dst`.

The resulting `dst` will always be NULL terminated if `n` is larger than 0, and the `dst` string will always be properly UTF-8 truncated.

Parameters

- **dst** – The destination of the UTF-8 string.
- **src** – The source string

- **n** – The size of the dst buffer. Maximum number of characters copied is n - 1. If 0 nothing will be done, and the dst will not be NULL terminated.

Returns
Pointer to the dst

static inline void **mem_xor_n**(uint8_t *dst, const uint8_t *src1, const uint8_t *src2, size_t len)

XOR n bytes.

Parameters

- **dst** – Destination of where to store result. Shall be len bytes.
- **src1** – First source. Shall be len bytes.
- **src2** – Second source. Shall be len bytes.
- **len** – Number of bytes to XOR.

static inline void **mem_xor_32**(uint8_t dst[4], const uint8_t src1[4], const uint8_t src2[4])

XOR 32 bits.

Parameters

- **dst** – Destination of where to store result. Shall be 32 bits.
- **src1** – First source. Shall be 32 bits.
- **src2** – Second source. Shall be 32 bits.

static inline void **mem_xor_128**(uint8_t dst[16], const uint8_t src1[16], const uint8_t src2[16])

XOR 128 bits.

Parameters

- **dst** – Destination of where to store result. Shall be 128 bits.
- **src1** – First source. Shall be 128 bits.
- **src2** – Second source. Shall be 128 bits.

3.10 Iterable Sections

This page contains the reference documentation for the iterable sections APIs, which can be used for defining iterable areas of equally-sized data structures, that can be iterated on using *STRUCT_SECTION_FOREACH*.

3.10.1 Usage

Iterable section elements are typically used by defining the data structure and associated initializer in a common header file, so that they can be instantiated anywhere in the code base.

```
struct my_data {
        int a, b;
};

#define DEFINE_DATA(name, _a, _b) \
        STRUCT_SECTION_ITERABLE(my_data, name) = { \
                .a = _a, \
                .b = _b, \
```

(continues on next page)

(continued from previous page)

```
        }

...

DEFINE_DATA(d1, 1, 2);
DEFINE_DATA(d2, 3, 4);
DEFINE_DATA(d3, 5, 6);
```

Then the linker has to be setup to place the place the structure in a contiguous segment using one of the linker macros such as *ITERABLE_SECTION_RAM* or *ITERABLE_SECTION_ROM*. Custom linker snippets are normally declared using one of the `zephyr_linker_sources()` CMake functions, using the appropriate section identifier, `DATA_SECTIONS` for RAM structures and `SECTIONS` for ROM ones.

```
# CMakeLists.txt
zephyr_linker_sources(DATA_SECTIONS iterables.ld)
```

```
# iterables.ld
ITERABLE_SECTION_RAM(my_data, 4)
```

The data can then be accessed using *STRUCT_SECTION_FOREACH*.

```
STRUCT_SECTION_FOREACH(my_data, data) {
        printk("%p: a: %d, b: %d\n", data, data->a, data->b);
}
```

Note

The linker is going to place the entries sorted by name, so the example above would visit `d1`, `d2` and `d3` in that order, regardless of how they were defined in the code.

3.10.2 API Reference

group **iterable_section_apis**

Iterable Sections APIs.

Defines

ITERABLE_SECTION_ROM(struct_type, subalign)

Define a read-only iterable section output.

Define an output section which will set up an iterable area of equally-sized data structures. For use with *STRUCT_SECTION_ITERABLE()*. Input sections will be sorted by name, per ld's SORT_BY_NAME.

This macro should be used for read-only data.

Note that this keeps the symbols in the image even though they are not being directly referenced. Use this when symbols are indirectly referenced by iterating through the section.

ITERABLE_SECTION_ROM_NUMERIC(struct_type, subalign)

Define a read-only iterable section output, sorted numerically.

This version of *ITERABLE_SECTION_ROM()* sorts the entries numerically, that is, SECNAME_10 will come after SECNAME_2. _ separator is required, and up to 2 numeric digits are handled (0-99).

See also

ITERABLE_SECTION_ROM()

ITERABLE_SECTION_ROM_GC_ALLOWED(struct_type, subalign)

Define a garbage collectable read-only iterable section output.

Define an output section which will set up an iterable area of equally-sized data structures. For use with *STRUCT_SECTION_ITERABLE()*. Input sections will be sorted by name, per ld's SORT_BY_NAME.

This macro should be used for read-only data.

Note that the symbols within the section can be garbage collected.

ITERABLE_SECTION_RAM(struct_type, subalign)

Define a read-write iterable section output.

Define an output section which will set up an iterable area of equally-sized data structures. For use with *STRUCT_SECTION_ITERABLE()*. Input sections will be sorted by name, per ld's SORT_BY_NAME.

This macro should be used for read-write data that is modified at runtime.

Note that this keeps the symbols in the image even though they are not being directly referenced. Use this when symbols are indirectly referenced by iterating through the section.

ITERABLE_SECTION_RAM_NUMERIC(struct_type, subalign)

Define a read-write iterable section output, sorted numerically.

This version of *ITERABLE_SECTION_RAM()* sorts the entries numerically, that is, SECNAME10 will come after SECNAME2. Up to 2 numeric digits are handled (0-99).

See also

ITERABLE_SECTION_RAM()

ITERABLE_SECTION_RAM_GC_ALLOWED(struct_type, subalign)

Define a garbage collectable read-write iterable section output.

Define an output section which will set up an iterable area of equally-sized data structures. For use with *STRUCT_SECTION_ITERABLE()*. Input sections will be sorted by name, per ld's SORT_BY_NAME.

This macro should be used for read-write data that is modified at runtime.

Note that the symbols within the section can be garbage collected.

TYPE_SECTION_ITERABLE(type, varname, secname, section_postfix)

Defines a new element for an iterable section for a generic type.

Convenience helper combining __in_section() and Z_DECL_ALIGN(). The section name will be '.[SECNAME].static.[SECTION_POSTFIX]'

In the linker script, create output sections for these using *ITERABLE_SECTION_ROM()* or *ITERABLE_SECTION_RAM()*.

> **Note**
>
> In order to store the element in ROM, a const specifier has to be added to the declaration: const *TYPE_SECTION_ITERABLE(...)*;

Parameters

- `type` – **[in]** data type of variable
- `varname` – **[in]** name of variable to place in section
- `secname` – **[in]** type name of iterable section.
- `section_postfix` – **[in]** postfix to use in section name

`TYPE_SECTION_START`(secname)

iterable section start symbol for a generic type

will return '_[OUT_TYPE]_list_start'.

Parameters

- `secname` – **[in]** type name of iterable section. For 'struct foobar' this would be *TYPE_SECTION_START(foobar)*

`TYPE_SECTION_END`(secname)

iterable section end symbol for a generic type

will return '_<SECNAME>_list_end'.

Parameters

- `secname` – **[in]** type name of iterable section. For 'struct foobar' this would be *TYPE_SECTION_START(foobar)*

`TYPE_SECTION_START_EXTERN`(type, secname)

iterable section extern for start symbol for a generic type

Helper macro to give extern for start of iterable section. The macro typically will be called *TYPE_SECTION_START_EXTERN(struct foobar, foobar)*. This allows the macro to hand different types as well as cases where the type and section name may differ.

Parameters

- `type` – **[in]** data type of section
- `secname` – **[in]** name of output section

`TYPE_SECTION_END_EXTERN`(type, secname)

iterable section extern for end symbol for a generic type

Helper macro to give extern for end of iterable section. The macro typically will be called *TYPE_SECTION_END_EXTERN(struct foobar, foobar)*. This allows the macro to hand different types as well as cases where the type and section name may differ.

Parameters

- `type` – **[in]** data type of section
- `secname` – **[in]** name of output section

TYPE_SECTION_FOREACH(type, secname, iterator)

Iterate over a specified iterable section for a generic type.

Iterator for structure instances gathered by *TYPE_SECTION_ITERABLE()*. The linker must provide a _<SECNAME>_list_start symbol and a _<SECNAME>_list_end symbol to mark the start and the end of the list of struct objects to iterate over. This is normally done using *ITERABLE_SECTION_ROM()* or *ITERABLE_SECTION_RAM()* in the linker script.

TYPE_SECTION_GET(type, secname, i, dst)

Get element from section for a generic type.

> **Note**
>
> There is no protection against reading beyond the section.

Parameters

- `type` – **[in]** type of element
- `secname` – **[in]** name of output section
- `i` – **[in]** Index.
- `dst` – **[out]** Pointer to location where pointer to element is written.

TYPE_SECTION_COUNT(type, secname, dst)

Count elements in a section for a generic type.

Parameters

- `type` – **[in]** type of element
- `secname` – **[in]** name of output section
- `dst` – **[out]** Pointer to location where result is written.

STRUCT_SECTION_START(struct_type)

iterable section start symbol for a struct type

Parameters

- `struct_type` – **[in]** data type of section

STRUCT_SECTION_START_EXTERN(struct_type)

iterable section extern for start symbol for a struct

Helper macro to give extern for start of iterable section.

Parameters

- `struct_type` – **[in]** data type of section

STRUCT_SECTION_END(struct_type)

iterable section end symbol for a struct type

Parameters

- `struct_type` – **[in]** data type of section

STRUCT_SECTION_END_EXTERN(struct_type)

iterable section extern for end symbol for a struct

Helper macro to give extern for end of iterable section.

Parameters

- `struct_type` – **[in]** data type of section

`STRUCT_SECTION_ITERABLE_ALTERNATE`(secname, struct_type, varname)

Defines a new element of alternate data type for an iterable section.

Special variant of *STRUCT_SECTION_ITERABLE()*, for placing alternate data types within the iterable section of a specific data type. The data type sizes and semantics must be equivalent!

`STRUCT_SECTION_ITERABLE_ARRAY_ALTERNATE`(secname, struct_type, varname, size)

Defines an array of elements of alternate data type for an iterable section.

See also

STRUCT_SECTION_ITERABLE_ALTERNATE

`STRUCT_SECTION_ITERABLE`(struct_type, varname)

Defines a new element for an iterable section.

Convenience helper combining __in_section() and Z_DECL_ALIGN(). The section name is the struct type prepended with an underscore. The subsection is “static” and the subsubsection is the variable name.

In the linker script, create output sections for these using *ITERABLE_SECTION_ROM()* or *ITERABLE_SECTION_RAM()*.

Note

In order to store the element in ROM, a const specifier has to be added to the declaration: const *STRUCT_SECTION_ITERABLE(...)*;

`STRUCT_SECTION_ITERABLE_ARRAY`(struct_type, varname, size)

Defines an array of elements for an iterable section.

See also

STRUCT_SECTION_ITERABLE

`STRUCT_SECTION_ITERABLE_NAMED`(struct_type, name, varname)

Defines a new element for an iterable section with a custom name.

The name can be used to customize how iterable section entries are sorted.

See also

STRUCT_SECTION_ITERABLE()

`STRUCT_SECTION_ITERABLE_NAMED_ALTERNATE`(struct_type, secname, name, varname)

Defines a new element for an iterable section with a custom name, placed in a custom section.

The name can be used to customize how iterable section entries are sorted.

See also

STRUCT_SECTION_ITERABLE_NAMED()

`STRUCT_SECTION_FOREACH_ALTERNATE`(secname, struct_type, iterator)

Iterate over a specified iterable section (alternate).

Iterator for structure instances gathered by *STRUCT_SECTION_ITERABLE()*. The linker must provide a _<SECNAME>_list_start symbol and a _<SECNAME>_list_end symbol to mark the start and the end of the list of struct objects to iterate over. This is normally done using *ITERABLE_SECTION_ROM()* or *ITERABLE_SECTION_RAM()* in the linker script.

`STRUCT_SECTION_FOREACH`(struct_type, iterator)

Iterate over a specified iterable section.

Iterator for structure instances gathered by *STRUCT_SECTION_ITERABLE()*. The linker must provide a _<struct_type>_list_start symbol and a _<struct_type>_list_end symbol to mark the start and the end of the list of struct objects to iterate over. This is normally done using *ITERABLE_SECTION_ROM()* or *ITERABLE_SECTION_RAM()* in the linker script.

`STRUCT_SECTION_GET`(struct_type, i, dst)

Get element from section.

Note

There is no protection against reading beyond the section.

Parameters

- `struct_type` – **[in]** Struct type.
- `i` – **[in]** Index.
- `dst` – **[out]** Pointer to location where pointer to element is written.

`STRUCT_SECTION_COUNT`(struct_type, dst)

Count elements in a section.

Parameters

- `struct_type` – **[in]** Struct type
- `dst` – **[out]** Pointer to location where result is written.

3.11 Code And Data Relocation

3.11.1 Overview

This feature will allow relocating .text, .rodata, .data, and .bss sections from required files and place them in the required memory region. The memory region and file are given to the *scripts/build/gen_relocate_app.py* script in the form of a string. This script is always invoked from inside cmake.

This script provides a robust way to re-order the memory contents without actually having to modify the code. In simple terms this script will do the job of `__attribute__((section("name")))` for a bunch of files together.

3.11.2 Details

The memory region and file are given to the *scripts/build/gen_relocate_app.py* script in the form of a string.

An example of such a string is: `SRAM2:/home/xyz/zephyr/samples/hello_world/src/main.c, SRAM1:/home/xyz/zephyr/samples/hello_world/src/main2.c`

This script is invoked with the following parameters: `python3 gen_relocate_app.py -i input_string -o generated_linker -c generated_code`

Kconfig `CONFIG_CODE_DATA_RELOCATION` option, when enabled in `prj.conf`, will invoke the script and do the required relocation.

This script also trigger the generation of `linker_relocate.ld` and `code_relocation.c` files. The `linker_relocate.ld` file creates appropriate sections and links the required functions or variables from all the selected files.

Note

The text section is split into 2 parts in the main linker script. The first section will have some info regarding vector tables and other debug related info. The second section will have the complete text section. This is needed to force the required functions and data variables to the correct locations. This is due to the behavior of the linker. The linker will only link once and hence this text section had to be split to make room for the generated linker script.

The `code_relocation.c` file has code that is needed for initializing data sections, and a copy of the text sections (if XIP). Also this contains code needed for bss zeroing and for data copy operations from ROM to required memory type.

The procedure to invoke this feature is:

- Enable `CONFIG_CODE_DATA_RELOCATION` in the `prj.conf` file
- Inside the `CMakeLists.txt` file in the project, mention all the files that need relocation.

  `zephyr_code_relocate(FILES src/*.c LOCATION SRAM2)`

  Where the first argument is the file/files and the second argument is the memory where it must be placed.

  Note

  function zephyr_code_relocate() can be called as many times as required.

Additional Configurations

This section shows additional configuration options that can be set in `CMakeLists.txt`

- if the memory is SRAM1, SRAM2, CCD, or AON, then place the full object in the sections for example:

```
zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2)
zephyr_code_relocate(FILES src/file2.c LOCATION SRAM)
```

- if the memory type is appended with _DATA, _TEXT, _RODATA or _BSS, only the selected memory is placed in the required memory region. for example:

```
zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2_DATA)
zephyr_code_relocate(FILES src/file2.c LOCATION SRAM2_TEXT)
```

- Multiple regions can also be appended together such as: SRAM2_DATA_BSS. This will place data and bss inside SRAM2.
- Multiple files can be passed to the FILES argument, or CMake generator expressions can be used to relocate a comma-separated list of files

```
file(GLOB sources "file*.c")
zephyr_code_relocate(FILES ${sources} LOCATION SRAM)
zephyr_code_relocate(FILES $<TARGET_PROPERTY:my_tgt,SOURCES> LOCATION SRAM)
```

NOKEEP flag

By default, all relocated functions and variables will be marked with `KEEP()` when generating `linker_relocate.ld`. Therefore, if any input file happens to contain unused symbols, then they will not be discarded by the linker, even when it is invoked with `--gc-sections`. If you'd like to override this behavior, you can pass `NOKEEP` to your `zephyr_code_relocate()` call.

```
zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2_TEXT NOKEEP)
```

The example above will help ensure that any unused code found in the .text sections of `file1.c` will not stick to SRAM2.

NOCOPY flag

When a `NOCOPY` option is passed to the `zephyr_code_relocate()` function, the relocation code is not generated in `code_relocation.c`. This flag can be used when we want to move the content of a specific file (or set of files) to a XIP area.

This example will place the .text section of the `xip_external_flash.c` file to the `EXTFLASH` memory region where it will be executed from (XIP). The .data will be relocated as usual into SRAM.

```
zephyr_code_relocate(FILES src/xip_external_flash.c LOCATION EXTFLASH_TEXT NOCOPY)
zephyr_code_relocate(FILES src/xip_external_flash.c LOCATION SRAM_DATA)
```

Relocating libraries

Libraries can be relocated using the LIBRARY argument to `zephyr_code_relocation()` with the library name. For example, the following snippet will relocate serial drivers to SRAM2:

```
zephyr_code_relocate(LIBRARY drivers__serial LOCATION SRAM2)
```

Tips

Take care if relocating kernel/arch files, some contain early initialization code that executes before code relocation takes place.

Additional MPU/MMU configuration may be required to ensure that the destination memory region is configured to allow code execution.

Samples/ Tests

A test showcasing this feature is provided at `$ZEPHYR_BASE/tests/application_development/code_relocation`

This test shows how the code relocation feature is used.

This test will place .text, .data, .bss from 3 files to various parts in the SRAM using a custom linker file derived from `include/zephyr/arch/arm/cortex_m/scripts/linker.ld`

A sample showcasing the NOCOPY flag is provided at `$ZEPHYR_BASE/samples/application_development/code_relocation_nocopy/`

Chapter 4

OS Services

4.1 Binary Descriptors

Binary Descriptors are constant data objects storing information about the binary executable. Unlike "regular" constants, binary descriptors are linked to a known offset in the binary, making them accessible to other programs, such as a different image running on the same device or a host tool. A few examples of constants that would make useful binary descriptors are: kernel version, app version, build time, compiler version, environment variables, compiling host name, etc.

Binary descriptors are created by using the `DEFINE_BINDESC_*` macros. For example:

```
#include <zephyr/bindesc.h>

BINDESC_STR_DEFINE(my_string, 2, "Hello world!"); // Unique ID is 2
```

`my_string` could then be accessed using:

```
printk("my_string: %s\n", BINDESC_GET_STR(my_string));
```

But it could also be retrieved by `west bindesc`:

```
$ west bindesc custom_search STR 2 build/zephyr/zephyr.bin
"Hello world!"
```

4.1.1 Internals

Binary descriptors are implemented with a TLV (tag, length, value) header linked to a known offset in the binary image. This offset may vary between architectures, but generally the descriptors are linked as close to the beginning of the image as possible. In architectures where the image must begin with a vector table (such as ARM), the descriptors are linked right after the vector table. The reset vector points to the beginning of the text section, which is after the descriptors. In architectures where the image must begin with executable code (e.g. x86), a jump instruction is injected at the beginning of the image, in order to skip over the binary descriptors, which are right after the jump instruction.

Each tag is a 16 bit unsigned integer, where the most significant nibble (4 bits) is the type (currently uint, string or bytes), and the rest is the ID. The ID is globally unique to each descriptor. For example, the ID of the app version string is `0x800`, and a string is denoted by 0x1, making the app version tag `0x1800`. The length is a 16 bit number equal to the length of the data in bytes. The data is the actual descriptor value. All binary descriptor numbers (magic, tags, uints) are laid out in memory in the endianness native to the SoC. `west bindesc` assumes little endian by

default, so if the image belongs to a big endian SoC, the appropriate flag should be given to the tool.

The binary descriptor header starts with the magic number `0xb9863e5a7ea46046`. It's followed by the TLVs, and ends with the `DESCRIPTORS_END` (`0xffff`) tag. The tags are always aligned to 32 bits. If the value of the previous descriptor had a non-aligned length, zero padding will be added to ensure that the current tag is aligned.

Putting it all together, here is what the example above would look like in memory (of a little endian SoC):

```
 46 60 a4 7e 5a 3e 86 b9 02 10  0d 00  48 65 6c 6c 6f 20 77 6f 72 6c 64 21 00 00 00 00 ff ff
|         magic         | tag |length| H  e  l  l  o     w  o  r  l  d  !    |   pad  | end␣
↪|
```

4.1.2 Usage

Binary descriptors are always created by the `BINDESC_*_DEFINE` macros. As shown in the example above, a descriptor can be generated from any string or integer, with any ID. However, it is recommended to comply with the standard tags defined in `include/zephyr/bindesc.h`, as that would have the following benefits:

1. The `west bindesc` tool would be able to recognize what the descriptor means and print a meaningful tag
2. It would enforce consistency between various apps from various sources
3. It allows upstream-ability of descriptor generation (see Standard Descriptors)

To define a descriptor with a standard tag, just use the tags included from `bindesc.h`:

```
#include <zephyr/bindesc.h>

BINDESC_STR_DEFINE(app_version, BINDESC_ID_APP_VERSION_STRING, "1.2.3");
```

Standard Descriptors

Some descriptors might be trivial to implement, and could therefore be implemented in a standard way in upstream Zephyr. These could then be enabled via Kconfig, instead of requiring every user to reimplement them. These include build times, kernel version, and host info. For example, to add the build date and time as a string, the following configs should be enabled:

```
# Enable binary descriptors
CONFIG_BINDESC=y

# Enable definition of binary descriptors
CONFIG_BINDESC_DEFINE=y

# Enable default build time binary descriptors
CONFIG_BINDESC_DEFINE_BUILD_TIME=y
CONFIG_BINDESC_BUILD_DATE_TIME_STRING=y
```

To avoid collisions with user defined descriptors, the standard descriptors were allotted the range between `0x800-0xfff`. This leaves `0x000-0x7ff` to users. For more information read the `help` sections of these Kconfig symbols. By convention, each Kconfig symbol corresponds to a binary descriptor whose name is the Kconfig name (with `CONFIG_BINDESC_` removed) in lower case. For example, `CONFIG_BINDESC_KERNEL_VERSION_STRING` creates a descriptor that can be accessed using `BINDESC_GET_STR(kernel_version_string)`.

west bindesc tool

`west` is able to parse and display binary descriptors from a given executable image.

For more information refer to `west bindesc --help` or the *documentation*.

The app version major such as 1.

`BINDESC_ID_APP_VERSION_MINOR`
The app version minor such as 2.

`BINDESC_ID_APP_VERSION_PATCHLEVEL`
The app version patchlevel such as 3.

`BINDESC_ID_APP_VERSION_NUMBER`
The app version number such as 0x10203.

`BINDESC_ID_KERNEL_VERSION_STRING`
The kernel version string such as "3.4.0".

`BINDESC_ID_KERNEL_VERSION_MAJOR`
The kernel version major such as 3.

`BINDESC_ID_KERNEL_VERSION_MINOR`
The kernel version minor such as 4.

`BINDESC_ID_KERNEL_VERSION_PATCHLEVEL`
The kernel version patchlevel such as 0.

`BINDESC_ID_KERNEL_VERSION_NUMBER`
The kernel version number such as 0x30400.

`BINDESC_ID_BUILD_TIME_YEAR`
: The year the image was compiled in.

`BINDESC_ID_BUILD_TIME_MONTH`
: The month of the year the image was compiled in.

`BINDESC_ID_BUILD_TIME_DAY`
: The day of the month the image was compiled in.

`BINDESC_ID_BUILD_TIME_HOUR`
: The hour of the day the image was compiled in.

`BINDESC_ID_BUILD_TIME_MINUTE`
: The minute the image was compiled in.

`BINDESC_ID_BUILD_TIME_SECOND`
: The second the image was compiled in.

`BINDESC_ID_BUILD_TIME_UNIX`
: The UNIX time (seconds since midnight of 1970/01/01) the image was compiled in.

`BINDESC_ID_BUILD_DATE_TIME_STRING`
: The date and time of compilation such as “2023/02/05 00:07:04”.

`BINDESC_ID_BUILD_DATE_STRING`
: The date of compilation such as “2023/02/05”.

`BINDESC_ID_BUILD_TIME_STRING`
: The time of compilation such as “00:07:04”.

`BINDESC_ID_HOST_NAME`
: The name of the host that compiled the image.

`BINDESC_ID_C_COMPILER_NAME`
: The C compiler name.

`BINDESC_ID_C_COMPILER_VERSION`
: The C compiler version.

`BINDESC_ID_CXX_COMPILER_NAME`
: The C++ compiler name.

`BINDESC_ID_CXX_COMPILER_VERSION`
: The C++ compiler version.

`BINDESC_TAG_DESCRIPTORS_END`

4.2 Console

Related code samples

Console echo
Echo an input character back to the output using the Console API.

group `console_api`

Console API.

Functions

int `console_init`(void)

Initialize console device.

This function should be called once to initialize pull-style access to console via *console_getchar()* function and buffered output using *console_putchar()* function. This function supersedes, and incompatible with, callback (push-style) console handling (via console_input_fn callback, etc.).

Returns
0 on success, error code (<0) otherwise

ssize_t `console_read`(void *dummy, void *buf, size_t size)

Read data from console.

Parameters

- `dummy` – ignored, present to follow read() prototype
- `buf` – buffer to read data to
- `size` – maximum number of bytes to read

Returns
>0, number of actually read bytes (can be less than size param) =0, in case of EOF <0, in case of error (e.g. -EAGAIN if timeout expired). errno variable is also set.

ssize_t `console_write`(void *dummy, const void *buf, size_t size)

Write data to console.

Parameters

- `dummy` – ignored, present to follow write() prototype
- `buf` – buffer to write data to
- `size` – maximum number of bytes to write

Returns
=>0, number of actually written bytes (can be less than size param) <0, in case of error (e.g. -EAGAIN if timeout expired). errno variable is also set.

int `console_getchar`(void)

Get next char from console input buffer.

Return next input character from console. If no characters available, this function will block. This function is similar to ANSI C getchar() function and is intended to ease porting of existing software. Before this function can be used, *console_init()* should be

called once. This function is incompatible with native Zephyr callback-based console input processing, shell subsystem, or *console_getline()*.

Returns
0-255: a character read, including control characters. <0: error occurred.

int **console_putchar**(char c)

Output a char to console (buffered).

Puts a character into console output buffer. It will be sent to a console asynchronously, e.g. using an IRQ handler.

Returns
<0 on error, otherwise 0.

void **console_getline_init**(void)

Initialize *console_getline()* call.

This function should be called once to initialize pull-style access to console via *console_getline()* function. This function supersedes, and incompatible with, callback (push-style) console handling (via console_input_fn callback, etc.).

char ***console_getline**(void)

Get next line from console input buffer.

Return next input line from console. Until full line is available, this function will block. This function is similar to ANSI C gets() function (except a line is returned in system-owned buffer, and system takes care of the buffer overflow checks) and is intended to ease porting of existing software. Before this function can be used, *console_getline_init()* should be called once. This function is incompatible with native Zephyr callback-based console input processing, shell subsystem, or *console_getchar()*.

Returns
A pointer to a line read, not including EOL character(s). A line resides in a system-owned buffer, so an application should finish any processing of this line immediately after *console_getline()* call, or the buffer can be reused.

4.3 Cryptography

The crypto section contains information regarding the cryptographic primitives supported by the Zephyr kernel. Use the information to understand the principles behind the operation of the different algorithms and how they were implemented.

The following crypto libraries have been included:

4.3.1 PSA Crypto

Overview

The PSA (Platform Security Architecture) Crypto API offers a portable programming interface for cryptographic operations and key storage across a wide range of hardware. It is designed to be user-friendly while still providing access to the low-level primitives essential for modern cryptography.

It is created and maintained by Arm. Arm developed the PSA as a comprehensive security framework to address the increasing security needs of connected devices.

In Zephyr, the PSA Crypto API is implemented using Mbed TLS, an open-source cryptographic library that provides the underlying cryptographic functions.

Design Goals

The interface is suitable for a vast range of devices: from special-purpose cryptographic processors that process data with a built-in key, to constrained devices running custom application code, such as microcontrollers, and multi-application devices, such as servers. It follows the principle of cryptographic agility.

Algorithm Flexibility
The PSA Crypto API supports a wide range of cryptographic algorithms, allowing developers to switch between different cryptographic methods as needed. This flexibility is crucial for maintaining security as new algorithms emerge and existing ones become obsolete.

Key Management
The PSA Crypto API includes robust key management features that support the creation, storage, and use of cryptographic keys in a secure and flexible manner. It uses opaque key identifiers, which allows for easy key replacement and updates without exposing key material.

Implementation Independence
The PSA Crypto API abstracts the underlying cryptographic library, meaning that the specific implementation can be changed without affecting the application code. This abstraction supports cryptographic agility by enabling the use of different cryptographic libraries or hardware accelerators as needed.

Future-Proofing
By adhering to cryptographic agility, PSA Crypto ensures that applications can quickly adapt to new cryptographic standards and practices, enhancing long-term security and compliance.

Examples of Applications

Network Security (TLS)
The API provides all of the cryptographic primitives needed to establish TLS connections.

Secure Storage
The API provides all primitives related to storage encryption, block or file-based, with master encryption keys stored inside a key store.

Network Credentials
The API provides network credential management inside a key store, for example, for X.509-based authentication or pre-shared keys on enterprise networks.

Device Pairing
The API provides support for key agreement protocols that are often used for secure pairing of devices over wireless channels. For example, the pairing of an NFC token or a Bluetooth device might use key agreement protocols upon first use.

Secure Boot
The API provides primitives for use during firmware integrity and authenticity validation, during a secure or trusted boot process.

Attestation
The API provides primitives used in attestation activities. Attestation is the ability for a device to sign an array of bytes with a device private key and return the result to the caller. There are several use cases; ranging from attestation of the device state, to the ability to generate a key pair and prove that it has been generated inside a secure key store. The API provides access to the algorithms commonly used for attestation.

Factory Provisioning
Most IoT devices receive a unique identity during the factory provisioning process, or once they have been deployed to the field. This API provides the APIs necessary for populating a device with keys that represent that identity.

Usage considerations

Always check for errors

Most functions in the PSA Crypto API can return errors. All functions that can fail have the return type `psa_status_t`. A few functions cannot fail, and thus, return void or some other type.

If an error occurs, unless otherwise specified, the content of the output parameters is undefined and must not be used.

Some common causes of errors include:

- In implementations where the keys are stored and processed in a separate environment from the application, all functions that need to access the cryptography processing environment might fail due to an error in the communication between the two environments.
- If an algorithm is implemented with a hardware accelerator, which is logically separate from the application processor, the accelerator might fail, even when the application processor keeps running normally.
- Most functions might fail due to a lack of resources. However, some implementations guarantee that certain functions always have sufficient memory.
- All functions that access persistent keys might fail due to a storage failure.
- All functions that require randomness might fail due to a lack of entropy. Implementations are encouraged to seed the random generator with sufficient entropy during the execution of `psa_crypto_init()`. However, some security standards require periodic reseeding from a hardware random generator, which can fail.

Shared memory and concurrency

Some environments allow applications to be multithreaded, while others do not. In some environments, applications can share memory with a different security context. In environments with multithreaded applications or shared memory, applications must be written carefully to avoid data corruption or leakage. This specification requires the application to obey certain constraints.

In general, the PSA Crypto API allows either one writer or any number of simultaneous readers, on any given object. In other words, if two or more calls access the same object concurrently, then the behavior is only well-defined if all the calls are only reading from the object and do not modify it. Read accesses include reading memory by input parameters and reading keystore content by using a key. For more details, refer to Concurrent calls

If an application shares memory with another security context, it can pass shared memory blocks as input buffers or output buffers, but not as non-buffer parameters. For more details, refer to Stability of parameters.

Cleaning up after use

To minimize impact if the system is compromised, it is recommended that applications wipe all sensitive data from memory when it is no longer used. That way, only data that is currently in use can be leaked, and past data is not compromised.

Wiping sensitive data includes:

- Clearing temporary buffers in the stack or on the heap.
- Aborting operations if they will not be finished.
- Destroying keys that are no longer used.

References

- PSA Crypto

- Mbed TLS

4.3.2 Random Number Generation

The random API subsystem provides random number generation APIs in both cryptographically and non-cryptographically secure instances. Which random API to use is based on the cryptographic requirements of the random number. The non-cryptographic APIs will return random values much faster if non-cryptographic values are needed.

The cryptographically secure random functions shall be compliant to the FIPS 140-2 [**?**] recommended algorithms. Hardware based random-number generators (RNG) can be used on platforms with appropriate hardware support. Platforms without hardware RNG support shall use the CTR-DRBG algorithm. The algorithm can be provided by TinyCrypt or mbedTLS depending on your application performance and resource requirements.

> **Note**
>
> The CTR-DRBG generator needs an entropy source to establish and maintain the cryptographic security of the PRNG.

Kconfig Options

These options can be found in the following path subsys/random/Kconfig.

`CONFIG_TEST_RANDOM_GENERATOR`
: For testing, this option allows a non-random number generator to be used and permits random number APIs to return values that are not truly random.

The random number generator choice group allows selection of the RNG source function for the system via the RNG_GENERATOR_CHOICE choice group. An override of the default value can be specified in the SOC or board .defconfig file by using:

```
choice RNG_GENERATOR_CHOICE
        default XOSHIRO_RANDOM_GENERATOR
endchoice
```

The random number generators available include:

`CONFIG_TIMER_RANDOM_GENERATOR`
: enables number generator based on system timer clock. This number generator is not random and used for testing only.

`CONFIG_ENTROPY_DEVICE_RANDOM_GENERATOR`
: enables a random number generator that uses the enabled hardware entropy gathering driver to generate random numbers.

`CONFIG_XOSHIRO_RANDOM_GENERATOR`
: enables the Xoshiro128++ pseudo-random number generator, that uses the entropy driver as a seed source.

The CSPRNG_GENERATOR_CHOICE choice group provides selection of the cryptographically secure random number generator source function. An override of the default value can be specified in the SOC or board .defconfig file by using:

```
choice CSPRNG_GENERATOR_CHOICE
        default CTR_DRBG_CSPRNG_GENERATOR
endchoice
```

The cryptographically secure random number generators available include:

`CONFIG_HARDWARE_DEVICE_CS_GENERATOR`
: enables a cryptographically secure random number generator using the hardware random generator driver

`CONFIG_CTR_DRBG_CSPRNG_GENERATOR`
: enables the CTR-DRBG pseudo-random number generator. The CTR-DRBG is a FIPS140-2 recommended cryptographically secure random number generator.

Personalization data can be provided in addition to the entropy source to make the initialization of the CTR-DRBG as unique as possible.

`CONFIG_CS_CTR_DRBG_PERSONALIZATION`
: CTR-DRBG Initialization Personalization string

Version
: 1.0.0

Functions

void `sys_rand_get`(void *dst, size_t len)

Fill the destination buffer with random data values that should pass general randomness tests.

Note

The random values returned are not considered cryptographically secure random number values.

Parameters

- `dst` – **[out]** destination buffer to fill with random data.
- `len` – size of the destination buffer.

int `sys_csrand_get`(void *dst, size_t len)

Fill the destination buffer with cryptographically secure random data values.

Note

If the random values requested do not need to be cryptographically secure then use *sys_rand_get()* instead.

Parameters

- `dst` – **[out]** destination buffer to fill.
- `len` – size of the destination buffer.

Returns

0 if success, -EIO if entropy reseed error

static inline uint8_t `sys_rand8_get`(void)

Return a 8-bit random value that should pass general randomness tests.

Note

The random value returned is not a cryptographically secure random number value.

Returns

8-bit random value.

static inline uint16_t `sys_rand16_get`(void)

Return a 16-bit random value that should pass general randomness tests.

Note

The random value returned is not a cryptographically secure random number value.

Returns

16-bit random value.

static inline uint32_t `sys_rand32_get`(void)

Return a 32-bit random value that should pass general randomness tests.

Note

The random value returned is not a cryptographically secure random number value.

Returns

32-bit random value.

static inline uint64_t `sys_rand64_get`(void)

Return a 64-bit random value that should pass general randomness tests.

Note

The random value returned is not a cryptographically secure random number value.

Returns
64-bit random value.

4.3.3 Crypto APIs

Overview

`CAP_RAW_KEY`

`CAP_KEY_LOADING_API`

`CAP_INPLACE_OPS`
Whether the output is placed in separate buffer or not.

`CAP_SEPARATE_IO_BUFS`

`CAP_SYNC_OPS`
These denotes if the output (completion of a cipher_xxx_op) is conveyed by the op function returning, or it is conveyed by an async notification.

`CAP_ASYNC_OPS`

`CAP_AUTONONCE`
Whether the hardware/driver supports autononce feature.

`CAP_NO_IV_PREFIX`
Don't prefix IV to cipher blocks.

Functions

static inline int **crypto_query_hwcaps**(const struct *device* *dev)
Query the crypto hardware capabilities.

This API is used by the app to query the capabilities supported by the crypto device. Based on this the app can specify a subset of the supported options to be honored for a session during *cipher_begin_session()*.

Parameters

- `dev` – Pointer to the device structure for the driver instance.

Returns
bitmask of supported options.

struct **crypto_driver_api**
#include <*crypto.h*> Crypto driver API definition.

Ciphers API

group `crypto_cipher`
Crypto Cipher APIs.

Typedefs

typedef int (***block_op_t**)(struct *cipher_ctx* *ctx, struct *cipher_pkt* *pkt)

typedef int (***cbc_op_t**)(struct *cipher_ctx* *ctx, struct *cipher_pkt* *pkt, uint8_t *iv)

typedef int (***ctr_op_t**)(struct *cipher_ctx* *ctx, struct *cipher_pkt* *pkt, uint8_t *ctr)

typedef int (***ccm_op_t**)(struct *cipher_ctx* *ctx, struct *cipher_aead_pkt* *pkt, uint8_t *nonce)

typedef void (***cipher_completion_cb**)(struct *cipher_pkt* *completed, int status)

Enums

enum **cipher_algo**
Cipher Algorithm.

Values:

enumerator `CRYPTO_CIPHER_ALGO_AES` = 1

enum **cipher_op**

Cipher Operation.

Values:

enumerator **CRYPTO_CIPHER_OP_DECRYPT** = 0

enumerator **CRYPTO_CIPHER_OP_ENCRYPT** = 1

enum **cipher_mode**

Possible cipher mode options.

More to be added as required.

Values:

enumerator **CRYPTO_CIPHER_MODE_ECB** = 1

enumerator **CRYPTO_CIPHER_MODE_CBC** = 2

enumerator **CRYPTO_CIPHER_MODE_CTR** = 3

enumerator **CRYPTO_CIPHER_MODE_CCM** = 4

enumerator **CRYPTO_CIPHER_MODE_GCM** = 5

Functions

static inline int **cipher_begin_session**(const struct *device* *dev, struct *cipher_ctx* *ctx, enum *cipher_algo* algo, enum *cipher_mode* mode, enum *cipher_op* optype)

Setup a crypto session.

Initializes one time parameters, like the session key, algorithm and cipher mode which may remain constant for all operations in the session. The state may be cached in hardware and/or driver data state variables.

Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **ctx** – Pointer to the context structure. Various one time parameters like key, keylength, etc. are supplied via this structure. The structure documentation specifies which fields are to be populated by the app before making this call.
- **algo** – The crypto algorithm to be used in this session. e.g AES
- **mode** – The cipher mode to be used in this session. e.g CBC, CTR
- **optype** – Whether we should encrypt or decrypt in this session

Returns

0 on success, negative errno code on fail.

static inline int **cipher_free_session**(const struct *device* *dev, struct *cipher_ctx* *ctx)

Cleanup a crypto session.

Clears the hardware and/or driver state of a previous session.

Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **ctx** – Pointer to the crypto context structure of the session to be freed.

Returns
0 on success, negative errno code on fail.

static inline int **cipher_callback_set**(const struct *device* *dev, *cipher_completion_cb* cb)

Registers an async crypto op completion callback with the driver.

The application can register an async crypto op completion callback handler to be invoked by the driver, on completion of a prior request submitted via cipher_do_op(). Based on crypto device hardware semantics, this is likely to be invoked from an ISR context.

Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **cb** – Pointer to application callback to be called by the driver.

Returns
0 on success, -ENOTSUP if the driver does not support async op, negative errno code on other error.

static inline int **cipher_block_op**(struct *cipher_ctx* *ctx, struct *cipher_pkt* *pkt)

Perform single-block crypto operation (ECB cipher mode).

This should not be overloaded to operate on multiple blocks for security reasons.

Parameters

- **ctx** – Pointer to the crypto context of this op.
- **pkt** – Structure holding the input/output buffer pointers.

Returns
0 on success, negative errno code on fail.

static inline int **cipher_cbc_op**(struct *cipher_ctx* *ctx, struct *cipher_pkt* *pkt, uint8_t *iv)

Perform Cipher Block Chaining (CBC) crypto operation.

Parameters

- **ctx** – Pointer to the crypto context of this op.
- **pkt** – Structure holding the input/output buffer pointers.
- **iv** – Initialization Vector (IV) for the operation. Same IV value should not be reused across multiple operations (within a session context) for security.

Returns
0 on success, negative errno code on fail.

static inline int **cipher_ctr_op**(struct *cipher_ctx* *ctx, struct *cipher_pkt* *pkt, uint8_t *iv)

Perform Counter (CTR) mode crypto operation.

Parameters

- **ctx** – Pointer to the crypto context of this op.
- **pkt** – Structure holding the input/output buffer pointers.

- `iv` – Initialization Vector (IV) for the operation. We use a split counter formed by appending IV and ctr. Consequently ivlen = keylen - ctrlen. 'ctrlen' is specified during session setup through the 'ctx.mode_params.ctr_params.ctr_len' parameter. IV should not be reused across multiple operations (within a session context) for security. The non-IV part of the split counter is transparent to the caller and is fully managed by the crypto provider.

Returns
0 on success, negative errno code on fail.

static inline int **cipher_ccm_op**(struct *cipher_ctx* *ctx, struct *cipher_aead_pkt* *pkt, uint8_t *nonce)

Perform Counter with CBC-MAC (CCM) mode crypto operation.

Parameters

- `ctx` – Pointer to the crypto context of this op.
- `pkt` – Structure holding the input/output, Associated Data (AD) and auth tag buffer pointers.
- `nonce` – Nonce for the operation. Same nonce value should not be reused across multiple operations (within a session context) for security.

Returns
0 on success, negative errno code on fail.

static inline int **cipher_gcm_op**(struct *cipher_ctx* *ctx, struct *cipher_aead_pkt* *pkt, uint8_t *nonce)

Perform Galois/Counter Mode (GCM) crypto operation.

Parameters

- `ctx` – Pointer to the crypto context of this op.
- `pkt` – Structure holding the input/output, Associated Data (AD) and auth tag buffer pointers.
- `nonce` – Nonce for the operation. Same nonce value should not be reused across multiple operations (within a session context) for security.

Returns
0 on success, negative errno code on fail.

struct **cipher_ops**

#include <*cipher.h*>

struct **ccm_params**

#include <*cipher.h*>

struct **ctr_params**

#include <*cipher.h*>

struct **gcm_params**

#include <*cipher.h*>

struct **cipher_ctx**

#include <*cipher.h*> Structure encoding session parameters.

Refer to comments for individual fields to know the contract in terms of who fills what and when w.r.t begin_session() call.

Public Members

struct *cipher_ops* **ops**

Place for driver to return function pointers to be invoked per cipher operation.

To be populated by crypto driver on return from begin_session() based on the algo/mode chosen by the app.

union *cipher_ctx* **key**

To be populated by the app before calling begin_session()

const struct *device* ***device**

The device driver instance this crypto context relates to.

Will be populated by the begin_session() API.

void ***drv_sessn_state**

If the driver supports multiple simultaneously crypto sessions, this will identify the specific driver state this crypto session relates to.

Since dynamic memory allocation is not possible, it is suggested that at build time drivers allocate space for the max simultaneous sessions they intend to support. To be populated by the driver on return from begin_session().

void ***app_sessn_state**

Place for the user app to put info relevant stuff for resuming when completion callback happens for async ops.

Totally managed by the app.

union *cipher_ctx* **mode_params**

Cypher mode parameters, which remain constant for all ops in a session.

To be populated by the app before calling begin_session().

uint16_t **keylen**

Cryptographic keylength in bytes.

To be populated by the app before calling begin_session()

uint16_t **flags**

How certain fields are to be interpreted for this session.

(A bitmask of CAP_* below.) To be populated by the app before calling begin_session(). An app can obtain the capability flags supported by a hw/driver by calling *crypto_query_hwcaps()*.

struct **cipher_pkt**

#include <*cipher.h*> Structure encoding IO parameters of one cryptographic operation like encrypt/decrypt.

The fields which has not been explicitly called out has to be filled up by the app before making the cipher_xxx_op() call.

Public Members

uint8_t *in_buf

Start address of input buffer.

int in_len

Bytes to be operated upon.

uint8_t *out_buf

Start of the output buffer, to be allocated by the application.

Can be NULL for in-place ops. To be populated with contents by the driver on return from op / async callback.

int out_buf_max

Size of the out_buf area allocated by the application.

Drivers should not write past the size of output buffer.

int out_len

To be populated by driver on return from cipher_xxx_op() and holds the size of the actual result.

struct *cipher_ctx* *ctx

Context this packet relates to.

This can be useful to get the session details, especially for async ops. Will be populated by the cipher_xxx_op() API based on the ctx parameter.

struct cipher_aead_pkt

#include <*cipher.h*> Structure encoding IO parameters in AEAD (Authenticated Encryption with Associated Data) scenario like in CCM.

App has to furnish valid contents prior to making *cipher_ccm_op()* call.

Public Members

uint8_t *ad

Start address for Associated Data.

This has to be supplied by app.

uint32_t ad_len

Size of Associated Data.

This has to be supplied by the app.

uint8_t *tag

Start address for the auth hash.

For an encryption op this will be populated by the driver when it returns from cipher_ccm_op call. For a decryption op this has to be supplied by the app.

4.4 Debugging

4.4.1 Thread analyzer

The thread analyzer module enables all the Zephyr options required to track the thread information, e.g. thread stack size usage and other runtime thread runtime statistics.

The analysis is performed on demand when the application calls *thread_analyzer_run()* or *thread_analyzer_print()*.

For example, to build the synchronization sample with Thread Analyser enabled, do the following:

```
west build -b qemu_x86 samples/synchronization/ -- -DCONFIG_QEMU_ICOUNT=n -
↪DCONFIG_THREAD_ANALYZER=y \
-DCONFIG_THREAD_ANALYZER_USE_PRINTK=y -DCONFIG_THREAD_ANALYZER_AUTO=y \
-DCONFIG_THREAD_ANALYZER_AUTO_INTERVAL=5
```

When you run the generated application in Qemu, you will get the additional information from Thread Analyzer:

```
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
 thread_b            : STACK: unused 740 usage 284 / 1024 (27 %); CPU: 0 %
 thread_analyzer     : STACK: unused 8 usage 504 / 512 (98 %); CPU: 0 %
 thread_a            : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 98 %
 idle                : STACK: unused 204 usage 116 / 320 (36 %); CPU: 0 %
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
 thread_b            : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 7 %
 thread_analyzer     : STACK: unused 8 usage 504 / 512 (98 %); CPU: 0 %
 thread_a            : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 9 %
 idle                : STACK: unused 204 usage 116 / 320 (36 %); CPU: 82 %
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
 thread_b            : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 7 %
 thread_analyzer     : STACK: unused 8 usage 504 / 512 (98 %); CPU: 0 %
 thread_a            : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 8 %
 idle                : STACK: unused 204 usage 116 / 320 (36 %); CPU: 83 %
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
```

Configuration

Configure this module using the following options.

- THREAD_ANALYZER: enable the module.
- THREAD_ANALYZER_USE_PRINTK: use printk for thread statistics.
- THREAD_ANALYZER_USE_LOG: use the logger for thread statistics.
- THREAD_ANALYZER_AUTO: run the thread analyzer automatically. You do not need to add any code to the application when using this option.
- THREAD_ANALYZER_AUTO_INTERVAL: the time for which the module sleeps between consecutive printing of thread analysis in automatic mode.
- THREAD_ANALYZER_AUTO_STACK_SIZE: the stack for thread analyzer automatic thread.
- THREAD_NAME: enable this option in the kernel to print the name of the thread instead of its ID.
- THREAD_RUNTIME_STATS: enable this option to print thread runtime data such as utilization (This options is automatically selected by THREAD_ANALYZER).

API documentation

group `thread_analyzer`

Module for analyzing threads.

This module implements functions and the configuration that simplifies thread analysis.

Typedefs

typedef void (***thread_analyzer_cb**)(struct *thread_analyzer_info* *info)

Thread analyzer stack size callback function.

Callback function with thread analysis information.

Param info
Thread analysis information.

Functions

void **thread_analyzer_run**(*thread_analyzer_cb* cb, unsigned int cpu)

Run the thread analyzer and provide information to the callback.

This function analyzes the current state for all threads and calls a given callback on every thread found. In the special case when Kconfig option THREAD_ANALYZER_AUTO_SEPARATE_CORES is set, the function analyzes only the threads running on the specified cpu.

Parameters

- **cb** – The callback function handler
- **cpu** – cpu to analyze, ignored if THREAD_ANALYZER_AUTO_SEPARATE_CORES=n

void **thread_analyzer_print**(unsigned int cpu)

Run the thread analyzer and print stack size statistics.

This function runs the thread analyzer and prints the output in standard form. In the special case when Kconfig option THREAD_ANALYZER_AUTO_SEPARATE_CORES is set, the function analyzes only the threads running on the specified cpu.

Parameters

- **cpu** – cpu to analyze, ignored if THREAD_ANALYZER_AUTO_SEPARATE_CORES=n

struct **thread_analyzer_info**

#include <thread_analyzer.h>

Public Members

const char ***name**

The name of the thread or stringified address of the thread handle if name is not set.

size_t **stack_size**

The total size of the stack.

size_t **stack_used**

Stack size in used.

4.4.2 Core Dump

The core dump module enables dumping the CPU registers and memory content for offline debugging. This module is called when a fatal error is encountered and prints or stores data according to which backends are enabled.

Configuration

Configure this module using the following options.

- DEBUG_COREDUMP: enable the module.

Here are the options to enable output backends for core dump:

- DEBUG_COREDUMP_BACKEND_LOGGING: use log module for core dump output.
- DEBUG_COREDUMP_BACKEND_FLASH_PARTITION: use flash partition for core dump output.
- DEBUG_COREDUMP_BACKEND_NULL: fallback core dump backend if other backends cannot be enabled. All output is sent to null.

Here are the choices regarding memory dump:

- DEBUG_COREDUMP_MEMORY_DUMP_MIN: only dumps the stack of the exception thread, its thread struct, and some other bare minimal data to support walking the stack in the debugger. Use this only if absolute minimum of data dump is desired.

Additional memory can be included in a dump (even with the "DEBUG_COREDUMP_MEMORY_DUMP_MIN" config selected) through one or more *coredump devices*

Usage

When the core dump module is enabled, during a fatal error, CPU registers and memory content are printed or stored according to which backends are enabled. This core dump data can fed into a custom-made GDB server as a remote target for GDB (and other GDB compatible debuggers). CPU registers, memory content and stack can be examined in the debugger.

This usually involves the following steps:

1. Get the core dump log from the device depending on enabled backends. For example, if the log module backend is used, get the log output from the log module backend.
2. Convert the core dump log into a binary format that can be parsed by the GDB server. For example, scripts/coredump/coredump_serial_log_parser.py can be used to convert the serial console log into a binary file.
3. Start the custom GDB server using the script scripts/coredump/coredump_gdbserver.py with the core dump binary log file, and the Zephyr ELF file as parameters. The GDB server can also be started from within GDB, see below.
4. Start the debugger corresponding to the target architecture.

> **Note**
>
> Developers for Intel ADSP CAVS 15-25 platforms using `ZEPHYR_TOOLCHAIN_VARIANT=zephyr` should use the debugger in the `xtensa-intel_apl_adsp` toolchain of the SDK.

5. When `DEBUG_COREDUMP_BACKEND_FLASH_PARTITION` is enabled the core dump data is stored in the flash partition. The flash partition must be defined in the device tree:

```
&flash0 {
        partitions {
                coredump_partition: partition@255000 {
                        label = "coredump-partition";
                        reg = <0x255000 DT_SIZE_K(4)>;
                };
};
```

Example This example uses the log module backend tied to serial console. This was done on qemu_x86 where a null pointer was dereferenced.

This is the core dump log from the serial console, and is stored in `coredump.log`:

```

E: Halting system
```

1. Run the core dump serial log converter:

   ```
   ./scripts/coredump/coredump_serial_log_parser.py coredump.log coredump.bin
   ```

2. Start the custom GDB server:

   ```
   ./scripts/coredump/coredump_gdbserver.py build/zephyr/zephyr.elf coredump.bin
   ```

3. Start GDB:

   ```
   <path to SDK>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb build/zephyr/zephyr.elf
   ```

4. Inside GDB, connect to the GDB server via port 1234:

   ```
   (gdb) target remote localhost:1234
   ```

5. Examine the CPU registers:

   ```
   (gdb) info registers
   ```

   Output from GDB:

   ```
   eax            0x0                 0
   ecx            0x119d74            1154420
   ```

(continues on next page)

(continued from previous page)

es             <unavailable>
fs             <unavailable>
gs             <unavailable>
```

6. Examine the backtrace:

```
(gdb) bt
```

Output from GDB:

```
#0  0x00100459 in func_3 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/src/main.
↪c:14
#1  0x00100477 in func_2 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/src/main.
↪c:21
#2  0x00100492 in func_1 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/src/main.
↪c:28
#3  0x001004c8 in main () at zephyr/rtos/zephyr/samples/hello_world/src/main.c:42
```

Starting the GDB server from within GDB You can use `target remote |` to start the custom GDB server from inside GDB, instead of in a separate shell.

1. Start GDB:

```
<path to SDK>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb build/zephyr/zephyr.elf
```

2. Inside GDB, start the GDB server using the `--pipe` option:

```
(gdb) target remote | ./scripts/coredump/coredump_gdbserver.py --pipe build/zephyr/
↪zephyr.elf coredump.bin
```

File Format

The core dump binary file consists of one file header, one architecture-specific block, and multiple memory blocks. All numbers in the headers below are little endian.

File Header The file header consists of the following fields:

Table 1: Core dump binary file header

Field	Data Type	Description
ID	`char[2]`	`Z`, `E` as identifier of file.
Header version	`uint16_`	Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.
Target code	`uint16_`	Indicate which target (e.g. architecture or SoC) so the parser can instantiate the correct register block parser.
Pointer size	'uint8_t'	Size of `uintptr_t` in power of 2. (e.g. 5 for 32-bit, 6 for 64-bit). This is needed to accommodate 32-bit and 64-bit target in parsing the memory block addresses.
Flags	`uint8_t`	
Fatal error reason	`unsigned int`	Reason for the fatal error, as the same in `enum k_fatal_error_reason` defined in include/zephyr/fatal.h

Architecture-specific Block The architecture-specific block contains the byte stream of data specific to the target architecture (e.g. CPU registers)

Table 2: Architecture-specific Block

Field	Data Type	Description
ID	`char`	`A` to indicate this is a architecture-specific block.
Header version	`uint16_`	Identify the version of this block. To be interpreted by the target architecture specific block parser.
Number of bytes	`uint16_`	Number of bytes following the header which contains the byte stream for target data. The format of the byte stream is specific to the target and is only being parsed by the target parser.
Register byte stream	`uint8_t`	Contains target architecture specific data.

Memory Block The memory block contains the start and end addresses and the data within the memory region.

Table 3: Memory Block

Field	Data Type	Description
ID	`char`	`M` to indicate this is a memory block.
Header version	`uint16_`	Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.
Start address	`uintptr_`	The start address of the memory region.
End address	`uintptr_`	The end address of the memory region.
Memory byte stream	`uint8_t`	Contains the memory content between the start and end addresses.

Adding New Target

The architecture-specific block is target specific and requires new dumping routine and parser for new targets. To add a new target, the following needs to be done:

1. Add a new target code to the `enum coredump_tgt_code` in include/zephyr/debug/coredump.h.
2. Implement *`arch_coredump_tgt_code_get()`* simply to return the newly introduced target code.
3. Implement *`arch_coredump_info_dump()`* to construct a target architecture block and call *`coredump_buffer_output()`* to output the block to core dump backend.
4. Add a parser to the core dump GDB stub scripts under `scripts/coredump/gdbstubs/`
    1. Extends the `gdbstubs.gdbstub.GdbStub` class.
    2. During `__init__`, store the GDB signal corresponding to the exception reason in `self.gdb_signal`.
    3. Parse the architecture-specific block from `self.logfile.get_arch_data()`. This needs to match the format as implemented in step 3 (inside *`arch_coredump_info_dump()`*).
    4. Implement the abstract method `handle_register_group_read_packet` where it returns the register group as GDB expected. Refer to GDB's code and documentation on what it is expecting for the new target.
    5. Optionally implement `handle_register_single_read_packet` for registers not covered in the `g` packet.
5. Extend `get_gdbstub()` in scripts/coredump/gdbstubs/__init__.py to return the newly implemented GDB stub.

API documentation

group **coredump_apis**

Coredump APIs.

Enums

enum **coredump_query_id**

Query ID.

Values:

enumerator **COREDUMP_QUERY_GET_ERROR**

Returns error code from backend.

enumerator **COREDUMP_QUERY_HAS_STORED_DUMP**

Check if there is a stored coredump from backend.

Returns:

- 1 if there is a stored coredump, 0 if none.
- -ENOTSUP if this query is not supported.
- Otherwise, error code from backend.

enumerator COREDUMP_QUERY_GET_STORED_DUMP_SIZE

Returns:

- coredump raw size from backend, 0 if none.
- -ENOTSUP if this query is not supported.
- Otherwise, error code from backend.

enumerator COREDUMP_QUERY_MAX

Max value for query ID.

enum coredump_cmd_id

Command ID.

Values:

enumerator COREDUMP_CMD_CLEAR_ERROR

Clear error code from backend.

Returns 0 if successful, failed otherwise.

enumerator COREDUMP_CMD_VERIFY_STORED_DUMP

Verify that the stored coredump is valid.

Returns:
- 1 if valid.
- 0 if not valid or no stored coredump.
- -ENOTSUP if this command is not supported.
- Otherwise, error code from backend.

enumerator COREDUMP_CMD_ERASE_STORED_DUMP

Erase the stored coredump.

Returns:
- 0 if successful.
- -ENOTSUP if this command is not supported.
- Otherwise, error code from backend.

enumerator COREDUMP_CMD_COPY_STORED_DUMP

Copy the raw stored coredump.

Returns:
- copied size if successful
- 0 if stored coredump is not found
- -ENOTSUP if this command is not supported.
- Otherwise, error code from backend.

enumerator COREDUMP_CMD_INVALIDATE_STORED_DUMP

Invalidate the stored coredump.

This is faster than erasing the whole partition.

Returns:
- 0 if successful.
- -ENOTSUP if this command is not supported.
- Otherwise, error code from backend.

enumerator COREDUMP_CMD_MAX

Max value for command ID.

Functions

static inline void **coredump**(unsigned int reason, const struct arch_esf *esf, struct *k_thread* *thread)

Perform coredump.

Normally, this is called inside z_fatal_error() to generate coredump when a fatal error is encountered. This can also be called on demand whenever a coredump is desired.

Parameters

- **reason** – Reason for the fatal error
- **esf** – Exception context
- **thread** – Thread information to dump

static inline void **coredump_memory_dump**(uintptr_t start_addr, uintptr_t end_addr)

Dump memory region.

Parameters

- **start_addr** – Start address of memory region to be dumped
- **end_addr** – End address of memory region to be dumped

static inline void **coredump_buffer_output**(uint8_t *buf, size_t buflen)

Output the buffer via coredump.

This outputs the buffer of byte array to the coredump backend. For example, this can be called to output the coredump section containing registers, or a section for memory dump.

Parameters

- **buf** – Buffer to be send to coredump output
- **buflen** – Buffer length

static inline int **coredump_query**(enum *coredump_query_id* query_id, void *arg)

Perform query on coredump subsystem.

Query the coredump subsystem for information, for example, if there is an error.

Parameters

- **query_id** – **[in]** Query ID
- **arg** – **[inout]** Pointer to argument for exchanging information

Returns

Depends on the query

static inline int **coredump_cmd**(enum *coredump_cmd_id* query_id, void *arg)

Perform command on coredump subsystem.

Perform command on coredump subsystem, for example, output the stored coredump via logging.

Parameters

- **cmd_id** – **[in]** Command ID
- **arg** – **[inout]** Pointer to argument for exchanging information

Returns
Depends on the command

struct **coredump_cmd_copy_arg**

#include <*coredump.h*> Coredump copy command (*CORE-DUMP_CMD_COPY_STORED_DUMP*) argument definition.

Public Members

off_t **offset**
Copy offset.

uint8_t ***buffer**
Copy destination buffer.

size_t **length**
Copy length.

group **arch-coredump**

Functions

void **arch_coredump_info_dump**(const struct arch_esf *esf)
Architecture-specific handling during coredump.

This dumps architecture-specific information during coredump.

Parameters
- **esf** – Exception Stack Frame (arch-specific)

uint16_t **arch_coredump_tgt_code_get**(void)
Get the target code specified by the architecture.

4.4.3 GDB stub

- *Overview*
- *Features*
- *Enabling GDB Stub*
  - *Using Serial Backend*
- *Debugging*
  - *Using Serial Backend*
- *Example*

Overview

The gdbstub feature provides an implementation of the GDB Remote Serial Protocol (RSP) that allows you to remotely debug Zephyr using GDB.

The protocol supports different connection types: serial, UDP/IP and TCP/IP. Zephyr currently supports only serial device communication.

The GDB program acts as a client while the Zephyr gdbstub acts as a server. When this feature is enabled, Zephyr stops its execution after `gdb_init()` starts gdbstub service and waits for a GDB connection. Once a connection is established it is possible to synchronously interact with Zephyr. Note that currently it is not possible to asynchronously send commands to the target.

Features

The following features are supported:

- Add and remove breakpoints
- Continue and step the target
- Print backtrace
- Read or write general registers
- Read or write the memory

Enabling GDB Stub

GDB stub can be enabled with the `CONFIG_GDBSTUB` option.

Using Serial Backend The serial backend for GDB stub can be enabled with the `CONFIG_GDBSTUB_SERIAL_BACKEND` option.

Since serial backend utilizes UART devices to send and receive GDB commands,

- If there are spare UART devices on the board, set `zephyr,gdbstub-uart` property of the chosen node to the spare UART device so that `printk()` and log messages are not being printed to the same UART device used for GDB.
- For boards with only one UART device, `printk()` and logging must be disabled if they are also using the same UART device for output. GDB related messages may interleave with log messages which may have unintended consequences. Usually this can be done by disabling `CONFIG_PRINTK` and `CONFIG_LOG`.

Debugging

Using Serial Backend

1. Build with GDB stub and serial backend enabled.
2. Flash built image onto board and reset the board.
   - Execution should now be paused at `gdb_init()`.
3. Execute GDB on development machine and connect to the GDB stub.

   ```
   target remote <serial device>
   ```

   For example,

```
target remote /dev/ttyUSB1
```

4. GDB commands can be used to start debugging.

Example

There is a test application tests/subsys/debug/gdbstub with one of its test cases `debug.gdbstub.breakpoints` demonstrating how the Zephyr GDB stub can be used. The test also has a case to connect to the QEMU's GDB stub implementation (at a custom port `tcp:1235`) as a reference to validate the test script itself.

Run the test with the following command from your *ZEPHYR_BASE* directory:

```
./scripts/twister -p qemu_x86 -T tests/subsys/debug/gdbstub
```

The test should run successfully, and now let's do something similar step-by-step to demonstrate how the Zephyr GDB stub works from the GDB user's perspective.

In the snippets below use and expect your appropriate directories instead of `<SDK install directory>`, `<build_directory>`, `<ZEPHYR_BASE>`.

1. Open two terminal windows.
2. On the first terminal, build and run the test application:

```
# From the root of the zephyr repository
west build -b qemu_x86 tests/subsys/debug/gdbstub -- '-DCONFIG_QEMU_EXTRA_FLAGS="-
↪serial tcp:localhost:5678,server"'
west build -t run
```

   Note how we set `CONFIG_QEMU_EXTRA_FLAGS` to direct QEMU serial console port to the `localhost` TCP port `5678` to wait for a connection from the GDB `remote` command we are going to do on the next steps.

3. On the second terminal, start GDB:

```
<SDK install directory>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb
```

   1. Tell GDB where to look for the built ELF file:

```
(gdb) symbol-file <build directory>/zephyr/zephyr.elf
```

      Response from GDB:

```
Reading symbols from <build directory>/zephyr/zephyr.elf...
```

   2. Tell GDB to connect to the Zephyr gdbstub serial backend which is exposed earlier as a server through the TCP port `-serial` redirection at QEMU.

```
(gdb) target remote localhost:5678
```

      Response from GDB:

```
Remote debugging using localhost:5678
arch_gdb_init () at <ZEPHYR_BASE>/arch/x86/core/ia32/gdbstub.c:252
252     }
```

      GDB also shows where the code execution is stopped. In this case, it is at arch/x86/core/ia32/gdbstub.c, line 252.

   3. Use command `bt` or `backtrace` to show the backtrace of stack frames.

```
(gdb) bt
#0  arch_gdb_init () at <ZEPHYR_BASE>/arch/x86/core/ia32/gdbstub.c:252
#1  0x00104140 in gdb_init () at <ZEPHYR_BASE>/zephyr/subsys/debug/gdbstub.c:852
#2  0x00109c13 in z_sys_init_run_level (level=INIT_LEVEL_PRE_KERNEL_2) at <ZEPHYR_
↪BASE>/kernel/init.c:360
#3  0x00109e73 in z_cstart () at <ZEPHYR_BASE>/kernel/init.c:630
#4  0x00104422 in z_prep_c (arg=0x1245bc <x86_cpu_boot_arg>) at <ZEPHYR_BASE>/
↪arch/x86/core/prep_c.c:80
#5  0x001000c9 in __csSet () at <ZEPHYR_BASE>/arch/x86/core/ia32/crt0.S:290
#6  0x001245bc in uart_dev ()
#7  0x00134988 in z_interrupt_stacks ()
#8  0x00000000 in ?? ()
```

4. Use command `list` to show the source code and surroundings where code execution is stopped.

```
(gdb) list
247             __asm__ volatile ("int3");
248
249     #ifdef CONFIG_GDBSTUB_TRACE
250             printk("gdbstub:%s GDB is connected\n", __func__);
251     #endif
252     }
253
254     /* Hook current IDT. */
255     _EXCEPTION_CONNECT_NOCODE(z_gdb_debug_isr, IV_DEBUG, 3);
256     _EXCEPTION_CONNECT_NOCODE(z_gdb_break_isr, IV_BREAKPOINT, 3);
```

5. Use command `s` or `step` to step through program until it reaches a different source line. Now that it finished executing *`arch_gdb_init()`* and is continuing in `gdb_init()`.

```
(gdb) s
gdb_init () at <ZEPHYR_BASE>/subsys/debug/gdbstub.c:857
857     return 0;
```

```
(gdb) list
852             arch_gdb_init();
853
854     #ifdef CONFIG_GDBSTUB_TRACE
855             printk("gdbstub:%s exit\n", __func__);
856     #endif
857             return 0;
858     }
859
860     #ifdef CONFIG_XTENSA
861     /*
```

6. Use command `br` or `break` to setup a breakpoint. For this example set up a breakpoint at `main()`, and let code execution continue without any intervention using command `c` (or `continue`).

```
(gdb) break main
Breakpoint 1 at 0x10064d: file <ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.
↪c, line 27.
```

```
(gdb) continue
Continuing.
```

Once code execution reaches `main()`, execution will be stopped and GDB prompt returns.

```
Breakpoint 1, main () at <ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.c:27
27              printk("%s():enter\n", __func__);
```

Now GDB is waiting at the beginning of `main()`:

```
(gdb) list
22
23      int main(void)
24      {
25              int ret;
26
27              printk("%s():enter\n", __func__);
28              ret = test();
29              printk("ret=%d\n", ret);
30              return 0;
31      }
```

7. To examine the value of `ret`, the command `p` or `print` can be used.

```
(gdb) p ret
$1 = 1273788
```

Since `ret` has not been initialized, it contains some random value.

8. If step (`s` or `step`) is used here, it will continue execution skipping the interior of `test()`. To examine code execution inside `test()`, a breakpoint can be set for `test()`, or simply using `si` (or `stepi`) to execute one machine instruction, where it has the side effect of going into the function. The GDB command `finish` can be used to continue execution without intervention until the function returns.

```
(gdb) finish
Run till exit from #0  test () at <ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/
↪main.c:17
0x00100667 in main () at <ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.c:28
28              ret = test();
Value returned is $2 = 30
```

9. Examine `ret` again which should have the return value from `test()`. Sometimes, the assignment is not done until another `step` is issued, as in this case. This is due to the assignment code is done after returning from function. The assignment code is generated by the toolchain as machine instructions which are not visible when viewing the corresponding C source file.

```
(gdb) p ret
$3 = 1273788
(gdb) step
29              printk("ret=%d\n", ret);
(gdb) p ret
$4 = 30
```

10. If `continue` is issued here, code execution will continue indefinitely as there are no breakpoints to further stop execution. Breaking execution in GDB via `Ctrl-C` does not currently work as the Zephyr gdbstub does not support this functionality yet. Switch to the first console with QEMU running the Zephyr image and stop it manually with `Ctrl+a x`. When the same test is executed by Twister, it automatically takes care of stopping the QEMU instance.

4.4.4 Cortex-M Debug Monitor

Monitor mode debugging is a Cortex-M feature, that provides a non-halting approach to debugging. With this it's possible to continue the execution of high-priority interrupts, even when waiting on a breakpoint. This strategy makes it possible to debug time-sensitive software, that would otherwise crash when the core halts (e.g. applications that need to keep communication links alive).

Zephyr provides support for enabling and configuring the Debug Monitor exception. It also contains a ready implementation of the interrupt, which can be used with SEGGER J-Link debuggers.

Configuration

Configure this module using the following options.

- `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK`: enable the module. This option, by itself, requires an implementation of debug monitor interrupt that will be executed every time the program enters a breakpoint.

With a SEGGER debug probe, it's possible to use a ready, SEGGER-provided implementation of the interrupt.

- `CONFIG_SEGGER_DEBUGMON`: enables SEGGER debug monitor interrupt. Can be used with SEGGER JLinkGDBServer and a SEGGER debug probe.

Usage

When monitor mode debugging is enabled, entering a breakpoint will not halt the processor, but rather generate an interrupt with ISR implemented under `z_arm_debug_monitor` symbol. `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK` config configures this interrupt to be the lowest available priority, which will allow other interrupts to execute while processor spins on a breakpoint.

Using SEGGER-provided ISR The ready implementation provided with `CONFIG_SEGGER_DEBUGMON` provides functionality required to debug in the monitor mode using regular GDB commands. Steps to configure SEGGER debug monitor:

1. Build a sample with `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK`` and `CONFIG_SEGGER_DEBUGMON` configs enabled.
2. Attach JLink GDB server to the target. Example linux command: `JLinkGDBServerCLExe -device <device> -if swd`.
3. Connect to the server with your GDB installation. Example linux command: `arm-none-eabi-gdb --ex="file build/zephyr.elf" --ex="target remote localhost:2331"`.
4. Enable monitor mode debugging in GDB using command: `monitor exec SetMonModeDebug=1`.

After these steps use regular gdb commands to debug your program.

Using other custom ISR In order to provide a custom debug monitor interrupt, override `z_arm_debug_monitor` symbol. Additionally, manual configuration of some registers is required (see debug monitor sample).

4.4.5 MIPI STP Decoder

The MIPI System Trace Protocol (MIPI STP) was developed as a generic base protocol that can be shared by multiple application-specific trace protocols. It serves as a wrapper protocol that merges disparate streams that typically contain different trace protocols from different trace sources. Stream consists of opcode (shortest is 4 bit long) followed by optional data and optional timestamp. There are opcodes for data (8, 16, 32, 64 bit data marked/not marked, with or without timestamp), stream recognition (master and channel), synchronization (ASYNC opcode) and others.

One example where protocol is used is ARM Coresight STM (System Trace Macrocell) where data written to Stimulus Port registers maps directly to STP stream.

This module can be used to perform on-chip decoding of the data stream. STP v2 is used.

Usage

Decoder is initialized with a callback. A callback is called on each decoded opcode. Decoder has internal state since there are dependency between opcodes (e.g. timestamp can be relative). Decoder can be in synchronization or not. Initial state is configurable. If decoder is not synchronized to the stream then it decodes each nibble in search for ASYNC opcode. Loss of synchronization can be indicated to the decoder by calling *mipi_stp_decoder_sync_loss()*. *mipi_stp_decoder_decode()* is used to decode the data.

Limitations

There are following limitations:

- Decoder supports only little endian architectures.
- When decoding nibbles, it is more efficient when core supports unaligned memory access. Implementation supports optimized version with unaligned memory access and generic one. Optimized version is used for ARM Cortex-M (expect for M0).
- Limited set of the most common opcodes is implemented.

API documentation

group `mipi_stp_decoder_apis`

Defines

`STP_DECODER_TYPE2STR`(_type)

Convert type to a string literal.

Parameters

- **`_type`** – type

Returns

String literal.

Typedefs

typedef void (*`mipi_stp_decoder_cb`)(enum *mipi_stp_decoder_ctrl_type* type, union *mipi_stp_decoder_data* data, uint64_t *ts, bool marked)

Callback signature.

Callback is called whenever an element from STPv2 stream is decoded.

> **Note**
>
> Callback is called with interrupts locked.

Param type
Type. See *mipi_stp_decoder_ctrl_type*.

Param data
Data. Data associated with a given `type`.

Param ts
Timestamp. Present if not NULL.

Param marked
Set to true if opcode was marked.

Enums

enum `mipi_stp_decoder_ctrl_type`

STPv2 opcodes.

Values:

enumerator `STP_DATA4` = 1

enumerator `STP_DATA8` = 2

enumerator `STP_DATA16` = 4

enumerator `STP_DATA32` = 8

enumerator `STP_DATA64` = 16

enumerator `STP_DECODER_NULL` = 128

enumerator `STP_DECODER_MASTER`

enumerator `STP_DECODER_MERROR`

enumerator `STP_DECODER_CHANNEL`

enumerator `STP_DECODER_VERSION`

enumerator STP_DECODER_FREQ

enumerator STP_DECODER_GERROR

enumerator STP_DECODER_FLAG

enumerator STP_DECODER_ASYNC

enumerator STP_DECODER_NOT_SUPPORTED

Functions

int **mipi_stp_decoder_init**(const struct *mipi_stp_decoder_config* *config)

Initialize the decoder.

Parameters

- **config** – Configuration.

Return values

- **0** – On successful initialization.
- **negative** – On failure.

int **mipi_stp_decoder_decode**(const uint8_t *data, size_t len)

Decode STPv2 stream.

Function decodes the stream and calls the callback for every decoded element.

Parameters

- **data** – Data.
- **len** – Data length.

Return values

- **0** – On successful decoding.
- **negative** – On failure.

void **mipi_stp_decoder_sync_loss**(void)

Indicate synchronization loss.

If detected, then decoder starts to look for ASYNC marker and drops all data until ASYNC is found. Synchronization can be lost when there is data loss (e.g. due to overflow).

union **mipi_stp_decoder_data**

#include <mipi_stp_decoder.h> Union with data associated with a given STP opcode.

Public Members

uint16_t **id**

ID - used for master and channel.

uint64_t **freq**
Frequency.

uint32_t **ver**
Version.

uint32_t **err**
Error code.

uint32_t **dummy**
Dummy.

uint64_t **data**
Data.

struct **mipi_stp_decoder_config**
#include <mipi_stp_decoder.h> Decoder configuration.

Public Members

bool **start_out_of_sync**
Indicates that decoder start in out of sync state.

mipi_stp_decoder_cb **cb**
Callback.

4.4.6 Symbol Table (Symtab)

The Symtab module, when enabled, will generate full symbol table during the Zephyr linking stage that keep tracks of the information about the functions' name and address, for advanced application with a lot of functions, this is expected to consume a sizable amount of ROM.

Currently, this is being used to look up the function names during a stack trace in supported architectures.

Usage

Application can gain access to the symbol table data structure by including the `symtab.h` header file and call *symtab_get()*. For now, we only provide *symtab_find_symbol_name()* function to look-up the symbol name and offset of an address. More advanced functionalities and be achieved by directly accessing the members of the data structure.

Configuration

Configure this module using the following options.

- `CONFIG_SYMTAB`: enable the generation of the symbol table.

API documentation

group `symtab_apis`

Functions

const struct *symtab_info* *const `symtab_get`(void)

Get the pointer to the symbol table.

Returns
Pointer to the symbol table.

const char *const `symtab_find_symbol_name`(uintptr_t addr, uint32_t *offset)

Find the symbol name with a binary search.

Parameters

- `addr` – **[in]** Address of the symbol to find
- `offset` – **[out]** Offset of the symbol from the nearest symbol. If the symbol can't be found, this will be 0.

Returns
Name of the nearest symbol if found, otherwise "?" is returned.

struct `symtab_info`

#include <symtab.h>

4.5 Device Management

4.5.1 MCUmgr

Overview

The management subsystem allows remote management of Zephyr-enabled devices. The following management operations are available:

- Image management
- File System management
- OS management
- Settings (config) management
- Shell management
- Statistic management
- Zephyr management

over the following transports:

- BLE (Bluetooth Low Energy)
- Serial (UART)
- UDP over IP

The management subsystem is based on the Simple Management Protocol (SMP) provided by MCUmgr, an open source project that provides a management subsystem that is portable across multiple real-time operating systems.

The management subsystem is located in subsys/mgmt/ inside of the Zephyr tree.

Additionally, there is a sample server that provides management functionality over BLE and serial.

Tools/libraries

There are various tools and libraries available which enable usage of MCUmgr functionality on a device which are listed below. Note that these tools are not part of or related to the Zephyr project.

Table 4: Tools and Libraries for MCUmgr

Name	OS support	Transports	Groups							Type	Language
			OS	IMG	Stat	Settings	FS	Shell	Zephyr		
AuTerm	Windows, Linux, macOS	Serial, Bluetooth, UDP	✓	✓	✓	✓	✓	✓	✓	App	C++ (Qt)
mcumgr-client	Windows, Linux, macOS	Serial	×	✓	×	×	×	×	×	App	Rust
mcumgr-web	Windows, Linux, macOS	Bluetooth	×	✓	×	×	×	×	×	Web (chrome only)	Javascript
nRF Connect Device Manager: Android and iOS	iOS, Android	Bluetooth	✓	✓	✓	✓	✓	✓	✓	Library, App	Java, Kotlin, Swift
Zephyr MCUmgr client (in-tree)	Linux, Zephyr	Serial, Bluetooth, UDP	✓	✓	×	×	×	×	×	Library	C

Note that a tick for a particular group indicates basic support for that group in the code, it is possible that not all commands/features of a group are supported by the implementation.

J-Link Virtual MSD Interaction Note

On boards where a J-Link OB is present which has both CDC and MSC (virtual Mass Storage Device, also known as drag-and-drop) support, the MSD functionality can prevent MCUmgr commands over the CDC UART port from working due to how USB endpoints are configured in the J-Link firmware (for example on the Nordic nrf52840dk/nrf52840 board) because of limiting the maximum packet size (most likely to occur when using image management commands for updating firmware). This issue can be resolved by disabling MSD functionality on the J-Link device, follow the instructions on nordic_segger_msd to disable MSD support.

Bootloader Integration

The *Device Firmware Upgrade* subsystem integrates the management subsystem with the bootloader, providing the ability to send and upgrade a Zephyr image to a device.

Currently only the MCUboot bootloader is supported. See *MCUboot* for more information.

Discord channel

Developers welcome!

API Reference

group `mcumgr_mgmt_api`

MCUmgr mgmt API.

Since
1.11

Version
1.0.0

Defines

`MGMT_CTXT_SET_RC_RSN`(mc, rsn)

`MGMT_CTXT_RC_RSN`(mc)

`MGMT_RETURN_CHECK`(ok)

Used at end of MCUmgr handlers to return an error if the message size limit was reached, or OK if it was not.

`MGMT_HDR_SIZE`

Typedefs

typedef void *(*`mgmt_alloc_rsp_fn`)(const void *src_buf, void *arg)

Allocates a buffer suitable for holding a response.

If a source buf is provided, its user data is copied into the new buffer.

Param src_buf
An optional source buffer to copy user data from.

Param arg
Optional streamer argument.

Return
Newly-allocated buffer on success NULL on failure.

typedef void (*`mgmt_reset_buf_fn`)(void *buf, void *arg)

Resets a buffer to a length of 0.

The buffer's user data remains, but its payload is cleared.

Param buf
The buffer to reset.

Param arg
Optional streamer argument.

typedef int (*`mgmt_handler_fn`)(struct smp_streamer *ctxt)

Processes a request and writes the corresponding response.

A separate handler is required for each supported op-ID pair.

Param ctxt
The mcumgr context to use.

Return
0 if a response was successfully encoded, *mcumgr_err_t* code on failure.

Enums

enum `mcumgr_op_t`

Opcodes; encoded in first byte of header.

Values:

enumerator `MGMT_OP_READ` = 0

Read op-code.

enumerator `MGMT_OP_READ_RSP`

Read response op-code.

enumerator `MGMT_OP_WRITE`

Write op-code.

enumerator `MGMT_OP_WRITE_RSP`

Write response op-code.

enum **mcumgr_group_t**

MCUmgr groups.

The first 64 groups are reserved for system level mcumgr commands. Per-user commands are then defined after group 64.

Values:

enumerator **MGMT_GROUP_ID_OS** = 0

OS (operating system) group.

enumerator **MGMT_GROUP_ID_IMAGE**

Image management group, used for uploading firmware images.

enumerator **MGMT_GROUP_ID_STAT**

Statistic management group, used for retrieving statistics.

enumerator **MGMT_GROUP_ID_SETTINGS**

Settings management (config) group, used for reading/writing settings.

enumerator **MGMT_GROUP_ID_LOG**

Log management group (unused)

enumerator **MGMT_GROUP_ID_CRASH**

Crash group (unused)

enumerator **MGMT_GROUP_ID_SPLIT**

Split image management group (unused)

enumerator **MGMT_GROUP_ID_RUN**

Run group (unused)

enumerator **MGMT_GROUP_ID_FS**

FS (file system) group, used for performing file IO operations.

enumerator **MGMT_GROUP_ID_SHELL**

Shell management group, used for executing shell commands.

enumerator **MGMT_GROUP_ID_PERUSER** = 64

User groups defined from 64 onwards.

enumerator **ZEPHYR_MGMT_GRP_BASIC** = (*MGMT_GROUP_ID_PERUSER* - 1)

Zephyr-specific groups decrease from PERUSER to avoid collision with upstream and user-defined groups.

Zephyr-specific: Basic group

enum **mcumgr_err_t**

MCUmgr error codes.

Values:

enumerator MGMT_ERR_EOK = 0
No error (success).

enumerator MGMT_ERR_EUNKNOWN
Unknown error.

enumerator MGMT_ERR_ENOMEM
Insufficient memory (likely not enough space for CBOR object).

enumerator MGMT_ERR_EINVAL
Error in input value.

enumerator MGMT_ERR_ETIMEOUT
Operation timed out.

enumerator MGMT_ERR_ENOENT
No such file/entry.

enumerator MGMT_ERR_EBADSTATE
Current state disallows command.

enumerator MGMT_ERR_EMSGSIZE
Response too large.

enumerator MGMT_ERR_ENOTSUP
Command not supported.

enumerator MGMT_ERR_ECORRUPT
Corrupt.

enumerator MGMT_ERR_EBUSY
Command blocked by processing of other command.

enumerator MGMT_ERR_EACCESSDENIED
Access to specific function, command or resource denied.

enumerator MGMT_ERR_UNSUPPORTED_TOO_OLD
Requested SMP MCUmgr protocol version is not supported (too old)

enumerator MGMT_ERR_UNSUPPORTED_TOO_NEW
Requested SMP MCUmgr protocol version is not supported (too new)

enumerator MGMT_ERR_EPERUSER = 256
User errors defined from 256 onwards.

Functions

void **mgmt_register_group**(struct *mgmt_group* *group)

Registers a full command group.

Parameters

- **group** – The group to register.

void **mgmt_unregister_group**(struct *mgmt_group* *group)

Unregisters a full command group.

Parameters

- **group** – The group to register.

const struct *mgmt_handler* ***mgmt_find_handler**(uint16_t group_id, uint16_t command_id)

Finds a registered command handler.

Parameters

- **group_id** – The group of the command to find.
- **command_id** – The ID of the command to find.

Returns

The requested command handler on success; NULL on failure.

const struct *mgmt_group* ***mgmt_find_group**(uint16_t group_id)

Finds a registered command group.

Parameters

- **group_id** – The group id of the command group to find.

Returns

The requested group on success; NULL on failure.

const struct *mgmt_handler* ***mgmt_get_handler**(const struct *mgmt_group* *group, uint16_t command_id)

Finds a registered command handler.

Parameters

- **group** – The group of the command to find.
- **command_id** – The ID of the command to find.

Returns

The requested command handler on success; NULL on failure.

struct **mgmt_handler**

#include <mgmt.h> Read handler and write handler for a single command ID.

Set use_custom_payload to true when using a user defined payload type

struct **mgmt_group**

#include <mgmt.h> A collection of handlers for an entire command group.

Public Members

sys_snode_t **node**

Entry list node.

const struct *mgmt_handler* **mg_handlers**
: Array of handlers; one entry per command ID.

uint16_t **mg_group_id**
: The numeric ID of this group.

4.5.2 MCUmgr handlers

Overview

MCUmgr functions by having group handlers which identify a group of functions relating to a specific management area, which is addressed with a 16-bit identification value, *mcumgr_group_t* contains the management groups available in Zephyr with their corresponding group ID values. The group ID is included in SMP headers to identify which group a command belongs to, there is also an 8-bit command ID which identifies the function of that group to execute - see *SMP Protocol Specification* for details on the SMP protocol and header. There can only be one registered group per unique ID.

Implementation

MCUmgr handlers can be added externally by application code or by module code, they do not have to reside in the upstream Zephyr tree to be usable. The first step to creating a handler is to create the folder structure for it, the typical Zephyr MCUmgr group layout is as follows:

```
<dir>/grp/<grp_name>_mgmt/
├── CMakeLists.txt
├── Kconfig
├── include
├──── <grp_name>_mgmt.h
├──── <grp_name>_mgmt_callbacks.h
├── src
└──── <grp_name>_mgmt.c
```

Note that the header files in upstream Zephyr MCUmgr handlers reside in the `zephyr/include/zephyr/mgmt/mcumgr/grp/<grp_name>_mgmt` directory to allow the files to be globally included by applications.

Initial header <grp_name>_mgmt.h The purpose of the header file is to provide defines which can be used by the MCUmgr handler itself and application code, e.g. to reference the command IDs for executing functions. An example file would look similar to:

```
/*
 * Copyright (c) 2023 Nordic Semiconductor ASA
 *
 * SPDX-License-Identifier: Apache-2.0
 */
#ifndef H_EXAMPLE_MGMT_
#define H_EXAMPLE_MGMT_

#ifdef __cplusplus
extern "C" {
#endif

/**
 * Group ID for example management group.
```

(continues on next page)

(continued from previous page)

```
 */
#define MGMT_GROUP_ID_EXAMPLE  MGMT_GROUP_ID_PERUSER

/**
 * Command IDs for example management group.
 */
#define EXAMPLE_MGMT_ID_TEST   0
#define EXAMPLE_MGMT_ID_OTHER  1

/**
 * Command result codes for example management group.
 */
enum example_mgmt_err_code_t {
        /** No error, this is implied if there is no ret value in the response */
        EXAMPLE_MGMT_ERR_OK = 0,

        /** Unknown error occurred. */
        EXAMPLE_MGMT_ERR_UNKNOWN,

        /** The provided value is not wanted at this time. */
        EXAMPLE_MGMT_ERR_NOT_WANTED,

        /** The provided value was rejected by a hook. */
        EXAMPLE_MGMT_ERR_REJECTED_BY_HOOK,
};

#ifdef __cplusplus
}
#endif

#endif
```

This provides the defines for 2 command `test` and `other` and sets up the SMP version 2 error responses (which have unique error codes per group as opposed to the legacy SMP version 1 error responses that return a *mcumgr_err_t* - there should always be an OK error code with the value 0 and an unknown error code with the value 1. The above example then adds an error code of `not wanted` with value 2. In addition, the group ID is set to be *MGMT_GROUP_ID_PERUSER*, which is the start group ID for user-defined groups, note that group IDs need to be unique so other custom groups should use different values, a central index header file (as upstream Zephyr has) can be used to distribute group IDs more easily.

Initial header <grp_name>_mgmt_callbacks.h The purpose of the header file is to provide defines which can be used by the MCUmgr handler itself and application code, e.g. to reference the command IDs for executing functions. An example file would look similar to:

```
/*
 * Copyright (c) 2023 Nordic Semiconductor ASA
 *
 * SPDX-License-Identifier: Apache-2.0
 */
#ifndef H_MCUMGR_EXAMPLE_MGMT_CALLBACKS_
#define H_MCUMGR_EXAMPLE_MGMT_CALLBACKS_
#include <stdint.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

#ifdef __cplusplus
extern "C" {
#endif

```

(continues on next page)

(continued from previous page)

```
/* This is the event ID for the example group */
#define MGMT_EVT_GRP_EXAMPLE MGMT_EVT_GRP_USER_CUSTOM_START

/* MGMT event opcodes for example management group */
enum example_mgmt_group_events {
        /* Callback when the other command is received, data is example_mgmt_other_data */
        MGMT_EVT_OP_EXAMPLE_OTHER = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_EXAMPLE, 0),

        /* Used to enable all smp_group events */
        MGMT_EVT_OP_EXAMPLE_MGMT_ALL  = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_EXAMPLE),
};

/* Structure provided in the #MGMT_EVT_OP_EXAMPLE_OTHER notification callback */
struct example_mgmt_other_data {
        /* Contains the user supplied value */
        uint32_t user_value;
};

#ifdef __cplusplus
}
#endif

#endif
```

This sets up a single event which application (or module) code can register for to receive a callback when the function handler is executed, which allows the flow of the handler to be changed (i.e. to return an error instead of continuing). The event group ID is set to *MGMT_EVT_GRP_USER_CUSTOM_START*, which is the start event ID for user-defined groups, note that event IDs need to be unique so other custom groups should use different values, a central index header file (as upstream Zephyr has) can be used to distribute event IDs more easily.

Initial source <grp_name>_mgmt.c The purpose of this source file is to handle the incoming MCUmgr commands, provide responses, and register the transport with MCUmgr so that commands will be sent to it. An example file would look similar to:

```
/*
 * Copyright (c) 2023 Nordic Semiconductor ASA
 *
 * SPDX-License-Identifier: Apache-2.0
 */
#include <zephyr/kernel.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>

147         switch (err) {
148         case EXAMPLE_MGMT_ERR_NOT_WANTED:
149                 rc = MGMT_ERR_ENOENT;
150                 break;
151
152         case EXAMPLE_MGMT_ERR_REJECTED_BY_HOOK:
153                 rc = MGMT_ERR_EBADSTATE;
154                 break;
155
156         case EXAMPLE_MGMT_ERR_UNKNOWN:
157         default:
158                 rc = MGMT_ERR_EUNKNOWN;
159         }
160
161         return rc;
162 }
163 #endif
164
165 static const struct mgmt_handler example_mgmt_handlers[] = {
166         [EXAMPLE_MGMT_ID_TEST] = {
167                 .mh_read = example_mgmt_test,
168                 .mh_write = NULL,
169         },
170         [EXAMPLE_MGMT_ID_OTHER] = {
171                 .mh_read = NULL,
172                 .mh_write = example_mgmt_other,
173         },
174 };
175
176 static struct mgmt_group example_mgmt_group = {
177         .mg_handlers = example_mgmt_handlers,
178         .mg_handlers_count = ARRAY_SIZE(example_mgmt_handlers),
179         .mg_group_id = MGMT_GROUP_ID_EXAMPLE,
180 #ifdef CONFIG_MCUMGR_SMP_SUPPORT_ORIGINAL_PROTOCOL
181         .mg_translate_error = example_mgmt_translate_error_code,
182 #endif
183 };
184
185 static void example_mgmt_register_group(void)
186 {
187         /* This function is called during system init before main() is invoked, if the
188          * handler needs to set anything up before it can be used, it should do it here.
189          * This register the group so that clients can call the function handlers.
190          */
191         mgmt_register_group(&example_mgmt_group);
192 }
193
194 MCUMGR_HANDLER_DEFINE(example_mgmt, example_mgmt_register_group);
```

The above code creates 2 function handlers, `test` which supports read requests and takes 2 re-

quired parameters, and `other` which supports write requests and takes 1 optional parameter, this function handler has an optional notification callback feature that allows other parts of the code to listen for the event and take any required actions that are necessary or prevent further execution of the function by returning an error, further details on MCUmgr callback functionality can be found on *MCUmgr Callbacks*.

Note that other code referencing callbacks for custom MCUmgr handlers needs to include both the base Zephyr callback include file and the custom handler callback file, only in-tree Zephyr handler headers are included when including the upstream Zephyr callback header file.

Initial Kconfig The purpose of the Kconfig file is to provide options which users can enable or change relating to the functionality of the handler being implemented. An example file would look similar to:

```
# Copyright Nordic Semiconductor ASA 2023. All rights reserved.
# SPDX-License-Identifier: Apache-2.0
# The Kconfig file is dedicated to example management group of
# of MCUmgr subsystem and provides Kconfig options to configure
# group commands behaviour and other aspects.
#
# Options defined in this file should be prefixed:
#  MCUMGR_GRP_EXAMPLE_ -- general group options;
#
# When adding Kconfig options, that control the same feature,
# try to group them together by the same stem after prefix.
if MCUMGR

menuconfig MCUMGR_GRP_EXAMPLE_APP
        bool "MCUmgr handlers for example management (app)"
        select MCUMGR_SMP_CBOR_MIN_DECODING_LEVEL_2
        default y
        help
          Enables MCUmgr handlers for example management. This demonstrates the
          file at application-level.

if MCUMGR_GRP_EXAMPLE_APP
config MCUMGR_GRP_EXAMPLE_OTHER_HOOK
        bool "Other hook"
        depends on MCUMGR_MGMT_NOTIFICATION_HOOKS
        help
          Allows applications to receive callback when the "other" example
          management function is called

module = MCUMGR_GRP_EXAMPLE
module-str = mcumgr_grp_example
source "subsys/logging/Kconfig.template.log_config"

endif

endif

source "Kconfig.zephyr"
```

Initial CMakeLists.txt The CMakeLists.txt file is used by the build system to setup files to compile, include directories to add and specify options that can be changed. A basic file only need to include the source files if the Kconfig options are enabled. An example file would look similar to:

Zephyr module

```
# Copyright (c) 2023 Nordic Semiconductor ASA
# SPDX-License-Identifier: Apache-2.0

if(CONFIG_MCUMGR_GRP_EXAMPLE_MODULE)
  zephyr_library(mgmt_mcumgr_grp_example)
  # The below should be updated with the real name of the file
  zephyr_library_sources(src/example_mgmt.c)
  zephyr_include_directories(include)
endif()
```

Application

```
if(CONFIG_MCUMGR_GRP_EXAMPLE_APP)
  target_sources(app PRIVATE example_as_module/src/example_mgmt.c)
  zephyr_include_directories(example_as_module/include)
endif()
```

Including from application

Application-specific MCUmgr handlers can be added by creating/editing application build files. Example modifications are shown below.

Example CMakeLists.txt The application `CMakeLists.txt` file can load the CMake file for the example MCUmgr handler by adding the following:

```
add_subdirectory(mcumgr/grp/<grp_name>)
```

Example Kconfig The application Kconfig file can include the Kconfig file for the example MCUmgr handler by adding the following to the `Kconfig` file in the application directory (or creating it if it does not exist):

```
rsource "mcumgr/grp/<grp_name>/Kconfig"

# Include Zephyr's Kconfig
source "Kconfig.zephyr"
```

Including from Zephyr Module

Zephyr *Modules (External projects)* can be used to add custom MCUmgr handlers to multiple different applications without needing to duplicate the code in each application's source tree, see *Module yaml file description* for details on how to set up the module files. Example files are shown below.

Example zephyr/module.yml This is an example file which can be used to load the Kconfig and CMake files from the root of the module directory, and would be placed at `zephyr/module.yml`:

```
build:
  kconfig: Kconfig
  cmake: .
```

Example CMakeLists.txt This is an example CMakeLists.txt file which loads the CMake file for the example MCUmgr handler, and would be placed at `CMakeLists.txt`:

```
add_subdirectory(mcumgr/grp/<grp_name>)
```

Example Kconfig This is an example Kconfig file which loads the Kconfig file for the example MCUmgr handler, and would be placed at `Kconfig`:

```
rsource "mcumgr/grp/<grp_name>/Kconfig"
```

Demonstration handler

There is a demonstration project which includes configuration for both application and zephyr module-MCUmgr handlers which can be used as a basis for created your own in tests/subsys/mgmt/mcumgr/handler_demo/.

4.5.3 MCUmgr Callbacks

Overview

MCUmgr has a customisable callback/notification system that allows application (and module) code to receive callbacks for MCUmgr events that they are interested in and react to them or return a status code to the calling function that provides control over if the action should be allowed or not. An example of this is with the fs_mgmt group, whereby file access can be gated, the callback allows the application to inspect the request path and allow or deny access to said file, or it can rewrite the provided path to a different path for transparent file redirection support.

Implementation

Enabling The base callback/notification system can be enabled using `CONFIG_MCUMGR_MGMT_NOTIFICATION_HOOKS` which will compile the registration and notification system into the code. This will not provide any callbacks by default as the callbacks that are supported by a build must also be selected by enabling the Kconfig's for the required callbacks (see *Events* for further details). A callback function with the *mgmt_cb* type definition can then be declared and registered by calling *mgmt_callback_register()* for the desired event inside of a :c:struct‘mgmt_callback‘ structure. Handlers are called in the order that they were registered.

With the system enabled, a basic handler can be set up and defined in application code as per:

```
#include <zephyr/kernel.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

struct mgmt_callback my_callback;

enum mgmt_cb_return my_function(uint32_t event, enum mgmt_cb_return prev_status,
                                int32_t *rc, uint16_t *group, bool *abort_more,
                                void *data, size_t data_size)
{
    if (event == MGMT_EVT_OP_CMD_DONE) {
        /* This is the event we registered for */
    }

    /* Return OK status code to continue with acceptance to underlying handler */
```

(continues on next page)

(continued from previous page)

```
    return MGMT_CB_OK;
}

int main()
{
    my_callback.callback = my_function;
    my_callback.event_id = MGMT_EVT_OP_CMD_DONE;
    mgmt_callback_register(&my_callback);
}
```

This code registers a handler for the *MGMT_EVT_OP_CMD_DONE* event, which will be called after a MCUmgr command has been processed and output generated, note that this requires that CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS be enabled to receive this callback.

Multiple callbacks can be setup to use a single function as a common callback, and many different functions can be used for each event by registering each group once, or all notifications for a whole group can be enabled by using one of the MGMT_EVT_OP_*_ALL events, alternatively a handler can setup for every notification by using *MGMT_EVT_OP_ALL*. When setting up handlers, events can be combined that are in the same group only, for example 5 img_mgmt callbacks can be setup with a single registration call, but to also setup a callback for an os_mgmt callback, this must be done as a separate registration. Group IDs are numerical increments, event IDs are bitmask values, hence the restriction.

As an example, the following registration is allowed, which will register for 3 SMP events with a single callback function in a single registration:

```
my_callback.callback = my_function;
my_callback.event_id = (MGMT_EVT_OP_CMD_RECV |
                        MGMT_EVT_OP_CMD_STATUS |
                        MGMT_EVT_OP_CMD_DONE);
mgmt_callback_register(&my_callback);
```

The following code is not allowed, and will cause undefined operation, because it mixes the IMG management group with the OS management group whereby the group is **not** a bitmask value, only the event is:

```
my_callback.callback = my_function;
my_callback.event_id = (MGMT_EVT_OP_IMG_MGMT_DFU_STARTED |
                        MGMT_EVT_OP_OS_MGMT_RESET);
mgmt_callback_register(&my_callback);
```

Events Events can be selected by enabling their corresponding Kconfig option:

- **CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS**
  MCUmgr command status (*MGMT_EVT_OP_CMD_RECV*, *MGMT_EVT_OP_CMD_STATUS*, *MGMT_EVT_OP_CMD_DONE*)
- **CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK**
  fs_mgmt file access (*MGMT_EVT_OP_FS_MGMT_FILE_ACCESS*)
- **CONFIG_MCUMGR_GRP_IMG_UPLOAD_CHECK_HOOK**
  img_mgmt upload check (*MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK*)
- **CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS**
  img_mgmt upload status (*MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED*, *MGMT_EVT_OP_IMG_MGMT_DFU_STARTED*, *MGMT_EVT_OP_IMG_MGMT_DFU_PENDING*, *MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED*)
- **CONFIG_MCUMGR_GRP_OS_RESET_HOOK**
  os_mgmt reset check (*MGMT_EVT_OP_OS_MGMT_RESET*)

- CONFIG_MCUMGR_GRP_SETTINGS_ACCESS_HOOK
  settings_mgmt access (*MGMT_EVT_OP_SETTINGS_MGMT_ACCESS*)

Actions Some callbacks expect a return status to either allow or disallow an operation, an example is the fs_mgmt access hook which allows for access to files to be allowed or denied. With these handlers, the first non-OK error code returned by a handler will be returned to the MCUmgr client.

An example of selectively denying file access:

```
#include <zephyr/kernel.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>
#include <string.h>

struct mgmt_callback my_callback;

enum mgmt_cb_return my_function(uint32_t event, enum mgmt_cb_return prev_status,
                                int32_t *rc, uint16_t *group, bool *abort_more,
                                void *data, size_t data_size)
{
    /* Only run this handler if a previous handler has not failed */
    if (event == MGMT_EVT_OP_FS_MGMT_FILE_ACCESS && prev_status == MGMT_CB_OK) {
        struct fs_mgmt_file_access *fs_data = (struct fs_mgmt_file_access *)data;

        /* Check if this is an upload and deny access if it is, otherwise check
         * the path and deny if is matches a name
         */
        if (fs_data->access == FS_MGMT_FILE_ACCESS_WRITE) {
            /* Return an access denied error code to the client and abort calling
             * further handlers
             */
            *abort_more = true;
            *rc = MGMT_ERR_EACCESSDENIED;

            return MGMT_CB_ERROR_RC;
        } else if (strcmp(fs_data->filename, "/lfs1/false_deny.txt") == 0) {
            /* Return a no entry error code to the client, call additional handlers
             * (which will have failed set to true)
             */
            *rc = MGMT_ERR_ENOENT;

            return MGMT_CB_ERROR_RC;
        }
    }

    /* Return OK status code to continue with acceptance to underlying handler */
    return MGMT_CB_OK;
}

int main()
{
    my_callback.callback = my_function;
    my_callback.event_id = MGMT_EVT_OP_FS_MGMT_FILE_ACCESS;
    mgmt_callback_register(&my_callback);
}
```

This code registers a handler for the *MGMT_EVT_OP_FS_MGMT_FILE_ACCESS* event, which will be called after a fs_mgmt file read/write command has been received to check if access to the file should be allowed or not, note that this requires that CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK be enabled to receive this callback. Two types of errors can be returned, the rc parameter can be set to an *mcumgr_err_t* error code and *MGMT_CB_ERROR_RC* can be returned, or a group error

code (introduced with version 2 of the MCUmgr protocol) can be set by setting the `group` value to the group and `rc` value to the group error code and returning *MGMT_CB_ERROR_ERR*.

MCUmgr Command Callback Usage/Adding New Event Types To add a callback to a MCUmgr command, *mgmt_callback_notify()* can be called with the event ID and, optionally, a data struct to pass to the callback (which can be modified by handlers). If no data needs to be passed back, `NULL` can be used instead, and size of the data set to 0.

An example MCUmgr command handler:

```
#include <zephyr/kernel.h>
#include <zcbor_common.h>
#include <zcbor_encode.h>
#include <zephyr/mgmt/mcumgr/smp/smp.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

#define MGMT_EVT_GRP_USER_ONE MGMT_EVT_GRP_USER_CUSTOM_START

enum user_one_group_events {
    /** Callback on first post, data is test_struct. */
    MGMT_EVT_OP_USER_ONE_FIRST  = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_USER_ONE, 0),

    /** Callback on second post, data is test_struct. */
    MGMT_EVT_OP_USER_ONE_SECOND = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_USER_ONE, 1),

    /** Used to enable all user_one events. */
    MGMT_EVT_OP_USER_ONE_ALL    = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_USER_ONE),
};

struct test_struct {
    uint8_t some_value;
};

static int test_command(struct mgmt_ctxt *ctxt)
{
    int rc;
    int err_rc;
    uint16_t err_group;
    zcbor_state_t *zse = ctxt->cnbe->zs;
    bool ok;
    struct test_struct test_data = {
        .some_value = 8,
    };

    rc = mgmt_callback_notify(MGMT_EVT_OP_USER_ONE_FIRST, &test_data,
                              sizeof(test_data), &err_rc, &err_group);

    if (rc != MGMT_CB_OK) {
        /* A handler returned a failure code */
        if (rc == MGMT_CB_ERROR_RC) {
            /* The failure code is the RC value */
            return err_rc;
        }

        /* The failure is a group and ID error value */
        ok = smp_add_cmd_err(zse, err_group, (uint16_t)err_rc);
        goto end;
    }

    /* All handlers returned success codes */
```

(continues on next page)

(continued from previous page)

```
    ok = zcbor_tstr_put_lit(zse, "output_value") &&
         zcbor_int32_put(zse, 1234);

end:
    rc = (ok ? MGMT_ERR_EOK : MGMT_ERR_EMSGSIZE);

    return rc;
}
```

If no response is required for the callback, the function call be called and casted to void.

Migration

If there is existing code using the previous callback system(s) in Zephyr 3.2 or earlier, then it will need to be migrated to the new system. To migrate code, the following callback registration functions will need to be migrated to register for callbacks using *mgmt_callback_register()* (note that CONFIG_MCUMGR_MGMT_NOTIFICATION_HOOKS will need to be set to enable the new notification system in addition to any migrations):

- **mgmt_evt**
  Using *MGMT_EVT_OP_CMD_RECV*, *MGMT_EVT_OP_CMD_STATUS*, or *MGMT_EVT_OP_CMD_DONE* as drop-in replacements for events of the same name, where the provided data is *mgmt_evt_op_cmd_arg*. CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS needs to be set.
- **fs_mgmt_register_evt_cb**
  Using *MGMT_EVT_OP_FS_MGMT_FILE_ACCESS* where the provided data is fs_mgmt_file_access. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, *MGMT_ERR_EOK* will allow the action, any other return code will disallow it and return that code to the client (*MGMT_ERR_EACCESSDENIED* can be used for an access denied error). CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS needs to be set.
- **img_mgmt_register_callbacks**
  Using *MGMT_EVT_OP_IMG_MGMT_DFU_STARTED* if dfu_started_cb was used, *MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED* if dfu_stopped_cb was used, *MGMT_EVT_OP_IMG_MGMT_DFU_PENDING* if dfu_pending_cb was used or *MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED* if dfu_confirmed_cb was used. These callbacks do not have any return status. CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS needs to be set.
- **img_mgmt_set_upload_cb**
  Using *MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK* where the provided data is img_mgmt_upload_check. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, *MGMT_ERR_EOK* will allow the action, any other return code will disallow it and return that code to the client (*MGMT_ERR_EACCESSDENIED* can be used for an access denied error). CONFIG_MCUMGR_GRP_IMG_UPLOAD_CHECK_HOOK needs to be set.
- **os_mgmt_register_reset_evt_cb**
  Using *MGMT_EVT_OP_OS_MGMT_RESET*. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, *MGMT_ERR_EOK* will allow the action, any other return code will disallow it and return that code to the client (*MGMT_ERR_EACCESSDENIED* can be used for an access denied error). CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS needs to be set.

API Reference

group `mcumgr_callback_api`

MCUmgr callback API.

Defines

`MGMT_EVT_GET_GROUP`(event)

Get group from event.

`MGMT_EVT_GET_ID`(event)

Get event ID from event.

`MGMT_CB_ERROR_RET`

Typedefs

typedef enum *mgmt_cb_return* (***mgmt_cb**)(uint32_t event, enum *mgmt_cb_return* prev_status, int32_t *rc, uint16_t *group, bool *abort_more, void *data, size_t data_size)

Function to be called on MGMT notification/event.

This callback function is used to notify an application or system about a MCUmgr mgmt event.

Param event
mcumgr_op_t.

Param prev_status
mgmt_cb_return of the previous handler calls, if it is an error then it will be the first error that was returned by a handler (i.e. this handler is being called for a notification only, the return code will be ignored).

Param rc
If `prev_status` is *MGMT_CB_ERROR_RC* then this is the SMP error that was returned by the first handler that failed. If `prev_status` is *MGMT_CB_ERROR_ERR* then this will be the group error rc code returned by the first handler that failed. If the handler wishes to raise an SMP error, this must be set to the *mcumgr_err_t* status and *MGMT_CB_ERROR_RC* must be returned by the function, if the handler wishes to raise a ret error, this must be set to the group ret status and *MGMT_CB_ERROR_ERR* must be returned by the function.

Param group
If `prev_status` is *MGMT_CB_ERROR_ERR* then this is the group of the ret error that was returned by the first handler that failed. If the handler wishes to raise a ret error, this must be set to the group ret status and *MGMT_CB_ERROR_ERR* must be returned by the function.

Param abort_more
Set to true to abort further processing by additional handlers.

Param data
Optional event argument.

Param data_size
Size of optional event argument (0 if no data is provided).

Return
mgmt_cb_return indicating the status to return to the calling code (only checked when this is the first failure reported by a handler).

Enums

enum `mgmt_cb_return`

MGMT event callback return value.

Values:

enumerator `MGMT_CB_OK`

No error.

enumerator `MGMT_CB_ERROR_RC`

SMP protocol error and `err_rc` contains the *mcumgr_err_t* error code.

enumerator `MGMT_CB_ERROR_ERR`

Group (application-level) error and `err_group` contains the group ID that caused the error and `err_rc` contains the error code of that group to return.

enum `mgmt_cb_groups`

MGMT event callback group IDs.

Note that this is not a 1:1 mapping with *mcumgr_group_t* values.

Values:

enumerator `MGMT_EVT_GRP_ALL` = 0

enumerator `MGMT_EVT_GRP_SMP`

enumerator `MGMT_EVT_GRP_OS`

enumerator `MGMT_EVT_GRP_IMG`

enumerator `MGMT_EVT_GRP_FS`

enumerator `MGMT_EVT_GRP_SETTINGS`

enumerator `MGMT_EVT_GRP_USER_CUSTOM_START` = *MGMT_GROUP_ID_PERUSER*

enum `smp_all_events`

MGMT event opcodes for all command processing.

Values:

enumerator `MGMT_EVT_OP_ALL` = MGMT_DEF_EVT_OP_ALL(*MGMT_EVT_GRP_ALL*)

Used to enable all events.

enum `smp_group_events`

MGMT event opcodes for base SMP command processing.

Values:

enumerator **MGMT_EVT_OP_CMD_RECV** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_SMP*, 0)

Callback when a command is received, data is *mgmt_evt_op_cmd_arg()*.

enumerator **MGMT_EVT_OP_CMD_STATUS** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_SMP*, 1)

Callback when a status is updated, data is *mgmt_evt_op_cmd_arg()*.

enumerator **MGMT_EVT_OP_CMD_DONE** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_SMP*, 2)

Callback when a command has been processed, data is *mgmt_evt_op_cmd_arg()*.

enumerator **MGMT_EVT_OP_CMD_ALL** = MGMT_DEF_EVT_OP_ALL(*MGMT_EVT_GRP_SMP*)

Used to enable all smp_group events.

enum **fs_mgmt_group_events**

MGMT event opcodes for filesystem management group.

Values:

enumerator **MGMT_EVT_OP_FS_MGMT_FILE_ACCESS** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_FS*, 0)

Callback when a file has been accessed, data is fs_mgmt_file_access().

enumerator **MGMT_EVT_OP_FS_MGMT_ALL** = MGMT_DEF_EVT_OP_ALL(*MGMT_EVT_GRP_FS*)

Used to enable all fs_mgmt_group events.

enum **img_mgmt_group_events**

MGMT event opcodes for image management group.

Values:

enumerator **MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_IMG*, 0)

Callback when a client sends a file upload chunk, data is img_mgmt_upload_check().

enumerator **MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_IMG*, 1)

Callback when a DFU operation is stopped.

enumerator **MGMT_EVT_OP_IMG_MGMT_DFU_STARTED** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_IMG*, 2)

Callback when a DFU operation is started.

enumerator **MGMT_EVT_OP_IMG_MGMT_DFU_PENDING** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_IMG*, 3)

Callback when a DFU operation has finished being transferred.

enumerator **MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_IMG*, 4)

Callback when an image has been confirmed.

enumerator **MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK_WRITE_COMPLETE** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_IMG*, 5)

Callback when an image write command has finished writing to flash.

enumerator **MGMT_EVT_OP_IMG_MGMT_ALL** = MGMT_DEF_EVT_OP_ALL(*MGMT_EVT_GRP_IMG*)

Used to enable all img_mgmt_group events.

enum **os_mgmt_group_events**

MGMT event opcodes for operating system management group.

Values:

enumerator **MGMT_EVT_OP_OS_MGMT_RESET** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_OS*, 0)

Callback when a reset command has been received, data is os_mgmt_reset_data.

enumerator **MGMT_EVT_OP_OS_MGMT_INFO_CHECK** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_OS*, 1)

Callback when an info command is processed, data is os_mgmt_info_check.

enumerator **MGMT_EVT_OP_OS_MGMT_INFO_APPEND** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_OS*, 2)

Callback when an info command needs to output data, data is os_mgmt_info_append.

enumerator **MGMT_EVT_OP_OS_MGMT_DATETIME_GET** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_OS*, 3)

Callback when a datetime get command has been received.

enumerator **MGMT_EVT_OP_OS_MGMT_DATETIME_SET** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_OS*, 4)

Callback when a datetime set command has been received, data is struct *rtc_time()*.

enumerator **MGMT_EVT_OP_OS_MGMT_ALL** = MGMT_DEF_EVT_OP_ALL(*MGMT_EVT_GRP_OS*)

Used to enable all os_mgmt_group events.

enum **settings_mgmt_group_events**

MGMT event opcodes for settings management group.

Values:

enumerator **MGMT_EVT_OP_SETTINGS_MGMT_ACCESS** = MGMT_DEF_EVT_OP_ID(*MGMT_EVT_GRP_SETTINGS*, 0)

Callback when a setting is read/written/deleted.

enumerator **MGMT_EVT_OP_SETTINGS_MGMT_ALL** = MGMT_DEF_EVT_OP_ALL(*MGMT_EVT_GRP_SETTINGS*)

Used to enable all settings_mgmt_group events.

Functions

uint8_t **mgmt_evt_get_index**(uint32_t event)

Get event ID index from event.

Parameters

- **event** – Event to get ID index from.

Returns

Event index.

enum *mgmt_cb_return* **mgmt_callback_notify**(uint32_t event, void *data, size_t data_size, int32_t *err_rc, uint16_t *err_group)

This function is called to notify registered callbacks about mcumgr notifications/events.

Parameters

- **event** – *mcumgr_op_t*.
- **data** – Optional event argument.
- **data_size** – Size of optional event argument (0 if none).
- **err_rc** – Pointer to rc value.
- **err_group** – Pointer to group value.

Returns

mgmt_cb_return either *MGMT_CB_OK* if all handlers returned it, or *MGMT_CB_ERROR_RC* if the first failed handler returned an SMP error (in which case `err_rc` will be updated with the SMP error) or *MGMT_CB_ERROR_ERR* if the first failed handler returned a ret group and error (in which case `err_group` will be updated with the failed group ID and `err_rc` will be updated with the group-specific error code).

void **mgmt_callback_register**(struct *mgmt_callback* *callback)

Register event callback function.

Parameters

- **callback** – Callback struct.

void **mgmt_callback_unregister**(struct *mgmt_callback* *callback)

Unregister event callback function.

Parameters

- **callback** – Callback struct.

struct **mgmt_callback**

#include <callbacks.h> MGMT callback struct.

Public Members

sys_snode_t **node**

Entry list node.

mgmt_cb **callback**

Callback that will be called.

uint32_t **event_id**

MGMT_EVT_[...] Event ID for handler to be called on.

This has special meaning if *MGMT_EVT_OP_ALL* is used (which will cover all events for all groups), or MGMT_EVT_OP_*_MGMT_ALL (which will cover all events for a single group). For events that are part of a single group, they can be or'd together for this to have one registration trigger on multiple events, please note that this will only work for a single group, to register for events in different groups, they must be registered separately.

struct **mgmt_evt_op_cmd_arg**

#include <*callbacks.h*> Arguments for *MGMT_EVT_OP_CMD_RECV*, *MGMT_EVT_OP_CMD_STATUS* and *MGMT_EVT_OP_CMD_DONE*.

Public Members

uint16_t **group**

mcumgr_group_t

uint8_t **id**

Message ID within group.

uint8_t **op**

mcumgr_op_t used in *MGMT_EVT_OP_CMD_RECV*

int **err**

mcumgr_err_t, used in *MGMT_EVT_OP_CMD_DONE*

int **status**

img_mgmt_id_upload_t, used in *MGMT_EVT_OP_CMD_STATUS*

4.5.4 Fixing and backporting fixes to Zephyr v2.7 MCUmgr

The processes described in this document apply to both the zephyr repository itself and the MCUmgr *module* defined in west.yml.

Note

Currently, the backporting process, described in this document, is required only when providing changes to Zephyr version 2.7 LTS

There are two different processes: one for issues that have also been fixed in the current version of Zephyr (backports), and one for issues that are being fixed only in a previous version.

The upstream MCUmgr repository is located in this page. The Zephyr fork used in version 2.7 and earlier is located here. Versions of Zephyr past 2.7 use the MCUmgr library that is part of the Zephyr code base.

Possible origins of a code change

In Zephyr version 2.7 and earlier, you must first apply the fix to the upstream repository of MCUmgr and then bring it to Zephyr with snapshot updates.

As such, there are four possible ways to apply a change to the 2.7 branch:

- The fix, done directly to the Zephyr held code of the MCUmgr library, is backported to the `v2.7-branch`.
- The fix, ported to the Zephyr held code from the upstream repository, is backported to the `v2.7-branch`.
- **The fix, done upstream and no longer relevant to the current version, is directly backported**
  to the `v2.7-branch`.
- **The fix, not present upstream and not relevant for the current version of Zephyr, is**
  directly applied to the `v2.7-branch`.

The first three cases are cases of *backports* , the last one is a case of a *new fix* and has no corresponding fix in the current version.

Applying fixes to previous versions of MCUmgr

This section indicates how to apply fixes to previous versions of MCUmgr.

Creating a bug report Every proposed fix requires a bug report submitted for the specified version of Zephyr affected by the bug.

In case the reported bug in a previous version has already been fixed in the current version, the description of the bug must be copied with the following:

- Additional references to the bug in the current version
- The PR for the current version
- The SHAs of the commits, if the PR has already been merged

You must also apply the `backport v2.7-branch` label to the bug report.

Creating the pull request for the fix You can either create a *backport pull request* or a *new-fix pull request*.

Creating backport pull requests Backporting a fix means that some or all of the fix commits, as they exist in the current version, are ported to a previous version.

> **Note**
>
> Backporting requires the fix for the current version to be already merged.

To create a backport pull request, do the following:

1. Port the fix commits from the current version to the previous version. Even if some of the commits require changes, keep the commit messages of all the ported commits as close to the ones in the original commits as possible, adding the following line:

```
"Backporting commit <sha>"

``<sha>`` indicates the SHA of the commit after it has been already merged in the current␣
↪version.
```

1. Create the pull request selecting `v2.7-branch` as the merge target.
2. Update `west.yml` within Zephyr, creating a pull-request to update the MCUmgr library referenced in Zephyr 2.7.

Creating new-fix pull requests When the fix needed does not have a corresponding fix in the current version, the bug report must follow the ordinary process.

1. Create the pull request selecting `v2.7-branch` as the merge target.
2. Update `west.yml` within Zephyr, creating a pull-request to update the MCUmgr library referenced in Zephyr 2.7.

Configuration management

This chapter describes the maintainers' side of accepting and merging fixes and backports.

Prerequisites As a maintainer, these are the steps required before proceeding with the merge process:

1. Check if the author has followed the correct steps that are required to apply the fix, as described in *Applying fixes to previous versions of MCUmgr*.

1. Ensure that the author of the fix has also provided the `west.yml` update for Zephyr 2.7.

The specific merging process depends on where the fix comes from and whether it is a *backport* or a *new fix*.

Merging a backported fix There are two possible sources of backports:

- The Zephyr code base
- A direct fix from upstream

Both cases are similar and differ only in the branch name.

To merge a backported fix after the pull request for the fix has gone through the review process, as a maintainer, do the following:

1. Create a branch named as follow:

   ```
   backport-<source>-<pr_num>-to_v2.7-branch
   ```

   `<source>` can be one of the following:

   - `upstream` - if the fix has originally been merged to the upstream repository.
   - `zephyr` - if the fix has been applied to the Zephyr internal MCUmgr library (past 2.7 versions).

   `<pr_num>` is the number of the original pull request that has already been merged.

   For example, a branch named `backport-upstream-137-to-v2.7-branch` indicates a backport of pull request 137, which has already been merged to the upstream repository of MCUmgr.

2. Push the reviewed pull-request branch to the newly created branch and merge the backport branch to `v2.7-branch`.

Merging a new fix Merging a new fix, that is not a backport of either any upstream or Zephyr fix, does not require any special treatment. Apply the fix directly at the top of `v2.7-branch`.

Merge west.yml As an MCUmgr maintainer, you may not be able to merge the `west.yml` update, to introduce the fix to Zephyr. However, you are responsible for such a merge to happen as soon as possible after the MCUmgr fixes have been applied to the `v2.7-branch` of the MCUmgr.

4.5.5 SMP Protocol Specification

This is description of Simple Management Protocol, SMP, that is used by MCUmgr to pass requests to devices and receive responses from them.

SMP is an application layer protocol. The underlying transport layer is not in scope of this documentation.

> **Note**
>
> SMP in this context refers to SMP for MCUmgr (Simple Management Protocol), it is unrelated to SMP in Bluetooth (Security Manager Protocol), but there is an MCUmgr SMP transport for Bluetooth.

Frame: The envelope

Each frame consists of a header and data. The `Data Length` field in the header may be used for reassembly purposes if underlying transport layer supports fragmentation. Frames are encoded in “Big Endian” (Network endianness) when fields are more than one byte long, and takes the following form:

3								2								1								0							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
Res			Ver		OP			Flags								Data Length																	
Group ID																Sequence Num								Command ID							
Data ...																															

> **Note**
>
> The original specification states that SMP should support receiving both the “Little-endian” and “Big-endian” frames but in reality the MCUmgr library is hardcoded to always treat “Network” side as “Big-endian”.

Data is optional and is not present when `Data Length` is zero. The encoding of data depends on the target of group/ID.

A description of the various fields and their meaning:

Field	Description
Res	This is reserved, not-used field and must be always set to 0.
Ver (Version)	This indicates the version of the protocol being used, this should be set to 0b01 to use the newer SMP transport where error codes are more detailed and returned in the map, otherwise left as 0b00 to use the legacy SMP protocol. Versions 0b10 and 0b11 are reserved for future use and should not be used.
OP	*mcumgr_op_t*, determines whether information is written to a device or requested from it and whether a packet contains request to an SMP server or response from it.
Flags	Reserved for flags; there are no flags defined yet, the field should be set to 0
Data Length	Length of the Data field
Group ID	*mcumgr_group_t*, see *Management Group ID's* for further details.
Sequence Num	This is a frame sequence number. The number is increased by one with each request frame. The Sequence Num of a response should match the one in the request.
Command ID	This is a command, within Group.
Data	This is data payload of the Data Length size. It is optional as Data Length may be set to zero, which means that no data follows the header.

Note

Contents of Data depends on a value of an OP, a Group ID, and a Command ID.

Management Group ID's The SMP protocol supports predefined common groups and allows user defined groups. The following table presents a list of common groups:

Decimal ID	Group description
0	*Default/OS Management Group*
1	*Application/software image management group*
2	*Statistics management*
3	*Settings (Config) Management Group*
4	Application/system log management (currently not used by Zephyr)
5	Run-time tests (unused by Zephyr)
6	Split image management (unused by Zephyr)
7	Test crashing application (unused by Zephyr)
8	*File management*
9	*Shell management*
63	*Zephyr Management Group*
64	This is the base group for defining an application specific management groups.

The payload for above groups, except for user groups (64 and above) is always CBOR encoded. The group 64, and above can define their own scheme for data communication.

Minimal response

Regardless of a command issued, as long as there is SMP client on the other side of a request, a response should be issued containing the header followed by CBOR map container. Lack of response is only allowed when there is no SMP service or device is non-responsive.

Minimal response SMP data Minimal response is:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Note that in the case of a successful command, an empty map will be returned (`rc`/`err` is only returned if there is an error condition, therefore if only an empty map is returned or a response lacks these, the request can be considered as being successful. For SMP version 2, errors relating to SMP itself that are not group specific will still be returned as `rc` errors, SMP version 2 clients must therefore be able to handle both types of errors.

Specifications of management groups supported by Zephyr

Default/OS Management Group OS management group defines following commands:

Command ID	Command description
0	Echo
1	Console/Terminal echo control; unimplemented by Zephyr
2	Task Statistics
3	Memory pool statistics
4	Date-time string
5	System reset
6	MCUMGR parameters
7	OS/Application info
8	Bootloader information

Echo command Echo command responses by sending back string that it has received.

Echo request Echo request header fields:

OP	Group ID	Command ID
0 or 2	0	0

CBOR data of request:

```
{
    (str)"d" : (str)
}
```

where:

“d”	string to be replied by echo service.

Echo response Echo response header fields:

OP	Group ID	Command ID	Note
1	0	0	When request OP was 0
3	0	0	When request OP was 2

CBOR data of successful response:

```
{
    (str)"r"        : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“r”	replying echo string.
“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Task statistics command The command responds with some system statistics.

Task statistics request Task statistics request header fields:

OP	Group ID	Command ID
0	0	2

The command sends an empty CBOR map as data.

Task statistics response Task statistics response header fields:

OP	Group ID	Command ID
1	0	2

CBOR data of successful response:

```
{
    (str)"tasks" : {
        (str)<task_name> : {
            (str)"prio"         : (uint)
            (str)"tid"          : (uint)
            (str)"state"        : (uint)
            (str)"stkuse"       : (uint)
            (str)"stksiz"       : (uint)
            (str)"cswcnt"       : (uint)
            (str)"runtime"      : (uint)
            (str)"last_checkin" : (uint)
            (str)"next_checkin" : (uint)
        }
        ...
    }
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

<task_nam	string identifying task.
“prio”	task priority.
“tid”	numeric task ID.
“state”	numeric task state.
“stkuse”	task’s/thread’s stack usage.
“stksiz”	task’s/thread’s stack size.
“cswcnt”	task’s/thread’s context switches.
“run-time”	task’s/thread’s runtime in “ticks”.
“last_check	set to 0 by Zephyr.
“next_chec	set to 0 by Zephyr.
“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Note

The unit for “stkuse” and “stksiz” is system dependent and in case of Zephyr this is number of 4 byte words.

Memory pool statistics The command is used to obtain information on memory pools active in running system.

Memory pool statistic request Memory pool statistics request header fields:

OP	Group ID	Command ID
0	0	3

The command sends an empty CBOR map as data.

Memory pool statistics response Memory pool statistics response header fields:

OP	Group ID	Command ID
1	0	3

CBOR data of successful response:

```
{
    (str)<pool_name> {
        (str)"blksiz"   : (int)
        (str)"nblks"    : (int)
        (str)"nfree"    : (int)
        (str)"min'      : (int)
    }
    ...
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

<pool_nam	string representing the pool name, used as a key for dictionary with pool statistics data.
“blksiz”	size of the memory block in the pool.
“nblks”	number of blocks in the pool.
“nfree”	number of free blocks.
“min”	lowest number of free blocks the pool reached during run-time.
“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Date-time command The command allows to obtain string representing current time-date on a device or set a new time to a device. The time format used, by both set and get operations, is:

“yyyy-MM-dd’T’HH:mm:ss.SSSSSSZZZZZ”

Date-time get The command allows to obtain date-time from a device.

Date-time get request Date-time request header fields:

OP	Group ID	Command ID
0	0	4

The command sends an empty CBOR map as data.

Date-time get response Date-time get response header fields:

OP	Group ID	Command ID
1	0	4

CBOR data of successful response:

```
{
    (str)"datetime" : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“date-time”	String in format: `yyyy-MM-dd'T'HH:mm:ss.SSSSSSZZZZZ`.
“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Date-time set The command allows to set date-time to a device.

Date-time set request Date-time set request header fields:

OP	Group ID	Command ID
2	0	4

CBOR data of response:

```
{
    (str)"datetime" : (str)
}
```

where:

“datetime”	String in format: `yyyy-MM-dd'T'HH:mm:ss.SSSSSSZZZZZ`.

Date-time set response Date-time set response header fields:

OP	Group ID	Command ID
3	0	4

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

System reset Performs reset of system. The device should issue response before resetting so that the SMP client could receive information that the command has been accepted. By default, this command is accepted in all conditions, however if the CONFIG_MCUMGR_GRP_OS_RESET_HOOK is enabled and an application registers a callback, the callback will be called when this command is issued and can be used to perform any necessary tidy operations prior to the module rebooting, or to reject the reset request outright altogether with an error response. For details on this functionality, see *ref:'mcumgr_callbacks*.

System reset request System reset request header fields:

OP	Group ID	Command ID
2	0	5

Normally the command sends an empty CBOR map as data, but if a previous reset attempt has responded with "rc" equal to *MGMT_ERR_EBUSY* then the following map may be sent to force a reset:

```
{
    (opt)"force"       : (int)
}
```

where:

"force"	Force reset if value > 0, optional if 0.

System reset response System reset response header fields

OP	Group ID	Command ID
3	0	5

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

MCUmgr Parameters Used to obtain parameters of mcumgr library.

MCUmgr Parameters Request MCUmgr parameters request header fields:

OP	Group ID	Command ID
0	0	6

The command sends an empty CBOR map as data.

MCUmgr Parameters Response MCUmgr parameters response header fields

OP	Group ID	Command ID
1	0	6

CBOR data of successful response:

```
{
    (str)"buf_size"     : (uint)
    (str)"buf_count"    : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"buf_size"	Single SMP buffer size, this includes SMP header and CBOR payload.
"buf_count	Number of SMP buffers supported.
"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

OS/Application Info Used to obtain information on running image, similar functionality to the linux uname command, allowing details such as kernel name, kernel version, build date/time, processor type and application-defined details to be returned. This functionality can be enabled with `CONFIG_MCUMGR_GRP_OS_INFO`.

OS/Application Info Request OS/Application info request header fields:

OP	Group ID	Command ID
0	0	7

CBOR data of request:

```
{
    (str,opt)"format"      : (str)
}
```

where:

"format'	Format specifier of returned response, fields are appended in their natural ascending index order, not the order of characters that are received by the command. Format specifiers: * `s` Kernel name * `n` Node name * `r` Kernel release * `v` Kernel version * `b` Build date and time (requires `CONFIG_MCUMGR_GRP_OS_INFO_BUILD_DATE_TIME`) * `m` Machine * `p` Processor * `i` Hardware platform * `o` Operating system * `a` All fields (shorthand for all above options) If this option is not provided, the `s` Kernel name option will be used.

OS/Application Info Response OS/Application info response header fields

OP	Group ID	Command ID
1	0	7

CBOR data of successful response:

```
{
    (str)"output"       : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"output"	Text response including requested parameters.
"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Bootloader Information Allows retrieving information about the on-board bootloader and its parameters.

Bootloader Information Request Bootloader information request header:

OP	Group ID	Command ID
0	0	8

CBOR data of request:

```
{
    (str,opt)"query"  : (str)
}
```

where:

“que	Is string representing query for parameters, with no restrictions how the query looks like as processing of query is left for bootloader backend. If there is no query, then response will return string identifying the bootloader.

Bootloader Information Response Bootloader information response header:

OP	Group ID	Command ID
1	0	8

In case when no “query” has been provided in request, CBOR data of response:

```
{
    (str)"bootloader"      : (str)
}
```

where:

“bootloader”	String representing bootloader name

In case when “query” is provided:

```
{
    (str,opt)<response>   : ()
    ...
}
```

where:

<re-spor	Response to “query”. This is optional and may be left out in case when query yields no response, SMP version 2 error code of *OS_MGMT_ERR_QUERY_YIELDS_NO_ANSWER* is expected. Response may have more than one parameter reported back or it may be a map, that is dependent on bootloader backednd and query.
...	Parameter characteristic information.

Parameter may be accompanied by additional, parameter specific, information keywords with assigned values.

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Bootloader Information: MCUboot In case when MCUboot is application bootloader, empty request will be responded with:

```
{
    (str)"bootloader"       : (str)"MCUboot"
}
```

Currently "MCUboot" supports querying for mode of operation:

```
{
    (str)"query"            : (str)"mode"
}
```

Response to "mode" is:

```
{
    (str)"mode"                     : (int)
    (str,opt)"no-downgrade"         : (bool)
}
```

where "mode" is one of:

-1	Unknown mode of MCUboot.
0	MCUboot is in single application mode.
1	MCUboot is in swap using scratch partition mode.
2	MCUboot is in overwrite (upgrade-only) mode.
3	MCUboot is in swap without scratch mode.
4	MCUboot is in DirectXIP without revert mode.
5	MCUboot is in DirectXIP with revert mode.
6	MCUboot is in RAM loader mode.

The `no-downgrade` field is a flag, which is always sent when true, indicating that MCUboot has downgrade prevention enabled; downgrade prevention means that if the uploaded image has a lower version than the currently running application, it will not be used for an update by MCUboot.

MCUmgr may reject images with a lower version in this configuration.

Application/software image management group Application/software image management group defines following commands:

Command ID	Command description
0	State of images
1	Image upload
2	File (reserved but not supported by Zephyr)
3	Corelist (reserved but not supported by Zephyr)
4	Coreload (reserved but not supported by Zephyr)
5	Image erase

Notion of "slots" and "images" in Zephyr The "slot" and "image" definition comes from mcuboot where "image" would consist of two "slots", further named "primary" and "secondary"; the application is supposed to run from the "primary slot" and update is supposed to be uploaded to the "secondary slot"; the mcuboot is responsible in swapping slots on boot. This means that pair of slots is dedicated to single upgradable application. In case of Zephyr this gets a little bit confusing because DTS will use "slot0_partition" and "slot1_partition", as label of `fixed-partition` dedicated to single application, but will name them as "image-0" and "image-1" respectively.

Currently Zephyr supports at most two images, in which case mapping is as follows:

Image	Slot labels	Slot Names
1	"slot0_partition" "slot1_partition"	"image-0" "image-1"
2	"slot2_partition" "slot3_partition"	"image-2" "image-3"

State of images The command is used to set state of images and obtain list of images with their current state.

Get state of images request Get state of images request header fields:

OP	Group ID	Command ID
0	1	0

The command sends an empty CBOR map as data.

Get state of images response Get state of images response header fields:

OP	Group ID	Command ID
1	1	0

Note

Below definition of the response contains "image" field that has been marked as optional(opt): the field may not appear in response when target application does not support more than one image. The field is mandatory when application supports more than one application image to allow identifying which image information is listed.

A response will only contain information for valid images, if an image can not be identified as valid it is simply skipped.

CBOR data of successful response:

```
{
    (str)"images" : [
        {
            (str,opt)"image"        : (uint)
            (str)"slot"             : (uint)
            (str)"version"          : (str)
            (str,opt*)"hash"        : (byte str)
            (str,opt)"bootable"     : (bool)
            (str,opt)"pending"      : (bool)
            (str,opt)"confirmed"    : (bool)
            (str,opt)"active"       : (bool)
            (str,opt)"permanent"    : (bool)
        }
        ...
    ]
    (str,opt)"splitStatus" : (int)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
    (str,opt)"rsn"  : (str)
}
```

where:

“image”	semi-optional image number; the field is not required when only one image is supported by the running application.
“slot”	slot number within “image”; each image has two slots : primary (running one) = 0 and secondary (for DFU dual-bank purposes) = 1.
“version”	string representing image version, as set with `imgtool`.
“hash”	SHA256 hash of the image header and body. Note that this will not be the same as the SHA256 of the whole file, it is the field in the MCUboot TLV section that contains a hash of the data which is used for signature verification purposes. This field is optional but only optional when using MCUboot’s serial recovery feature with one pair of image slots, Kconfig `CONFIG_BOOT_SERIAL_IMG_GRP_HASH` can be disabled to remove support for hashes in this configuration. MCUmgr in applications must support sending hashes. **Note** See `IMAGE_TLV_SHA256` in the MCUboot image format documentation link below.
“bootable”	true if image has bootable flag set; this field does not have to be present if false.
“pending”	true if image is set for next swap; this field does not have to be present if false.
“confirmed”	true if image has been confirmed; this field does not have to be present if false.
“active”	true if image is currently active application; this field does not have to be present if false.
“permanent”	true if image is to stay in primary slot after the next boot; this does not have to be present if false.
“splitStatus”	states whether loader of split image is compatible with application part; this is unused by Zephyr.
“err” -> “group”	*`mcumgr_group_t`* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*`mcumgr_err_t`* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
“rsn”	optional string that clarifies reason for an error; specifically useful when `rc` is *`MGMT_ERR_EUNKNOWN`*.

Note

For more information on how does image/slots function, please refer to the MCUBoot documentation https://docs.mcuboot.com/design.html#image-slots For information on MCUboot image format, please reset to the MCUboot documentation https://docs.mcuboot.com/design.html#image-format

Set state of image request Set state of image request header fields:

OP	Group ID	Command ID
2	1	0

CBOR data of request:

```
{
    (str,opt)"hash"     : (str)
    (str)"confirm"      : (bool)
}
```

If "confirm" is false or not provided, an image with the "hash" will be set for test, which means that it will not be marked as permanent and upon hard reset the previous application will be restored to the primary slot. In case when "confirm" is true, the "hash" is optional as the currently running application will be assumed as target for confirmation.

Set state of image response The response takes the same format as *Get state of images response*

Image upload The image upload command allows to update application image.

Image upload request The image upload request is sent for each chunk of image that is uploaded, until complete image gets uploaded to a device.

Image upload request header fields:

OP	Group ID	Command ID
2	1	1

CBOR data of request:

```
{
    (str,opt)"image"    : (uint)
    (str,opt)"len"      : (uint)
    (str)"off"          : (uint)
    (str,opt)"sha"      : (byte str)
    (str)"data"         : (byte str)
    (str,opt)"upgrade"  : (bool)
}
```

where:

“image”	optional image number, it does not have to appear in request at all, in which case it is assumed to be 0. Should only be present when “off” is 0.
“len”	optional length of an image. Must appear when “off” is 0.
“off”	offset of image chunk the request carries.
“sha”	SHA256 hash of an upload; this is used to identify an upload session (e.g. to allow MCUmgr to continue a broken session), and for image verification purposes. This must be a full SHA256 hash of the whole image being uploaded, or not included if the hash is not available (in which case, upload session continuation and image verification functionality will be unavailable). Should only be present when “off” is 0.
“data”	image data to write at provided offset.
“upgrade”	optional flag that states that only upgrade should be allowed, so if the version of uploaded software is not higher then already on a device, the image upload will be rejected. Zephyr compares major, minor and revision (x.y.z) by default unless `CONFIG_MCUMGR_GRP_IMG_VERSION_CMP_USE_BUILD_NUMBER` is set, whereby it will compare build numbers too. Should only be present when “off” is 0.

Note

There is no field representing size of chunk that is carried as “data” because that information is embedded within “data” field itself.

Note

It is possible that a server will respond to an upload with “off” of 0, this may happen if an upload on another transport (or outside of MCUmgr entirely) is started, if the device has rebooted or if a packet has been lost. If this happens, a client must re-send all the required and optional fields that it sent in the original first packet so that the upload state can be re-created by the server. If the original fields are not included, the upload will be unable to continue.

The MCUmgr library uses “sha” field to tag ongoing update session, to be able to continue it in case when it gets broken, and for upload verification purposes. If library gets request with “off” equal zero it checks stored “sha” within its state and if it matches it will respond to update client application with offset that it should continue with. If this hash is not available (e.g. because a file is being streamed) then it must not be provided, image verification and upload session continuation features will be unavailable in this case.

Image upload response Image upload response header fields:

OP	Group ID	Command ID
3	1	1

CBOR data of successful response:

```
{
    (str,opt)"off"    : (uint)
    (str,opt)"match"  : (bool)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
    (str,opt)"rsn"  : (str)
}
```

where:

"off"	offset of last successfully written byte of update.
"match"	indicates if the uploaded data successfully matches the provided SHA256 hash or not, only sent in the final packet if `CONFIG_IMG_ENABLE_IMAGE_CHECK` is enabled.
"err" -> "group"	*`mcumgr_group_t`* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*`mcumgr_err_t`* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
"rsn"	optional string that clarifies reason for an error; specifically useful when `rc` is *`MGMT_ERR_EUNKNOWN`*.

The "off" field is only included in responses to successfully processed requests; if "rc" is negative then "off" may not appear.

Image erase The command is used for erasing image slot on a target device.

> **Note**
>
> This is synchronous command which means that a sender of request will not receive response until the command completes, which can take a long time.

Image erase request Image erase request header fields:

OP	Group ID	Command ID
2	1	5

CBOR data of request:

```
{
    (str,opt)"slot"     : (uint)
}
```

where:

"slot"	optional slot number, it does not have to appear in the request at all, in which case it is assumed to be 1.

Image erase response Image erase response header fields:

OP	Group ID	Command ID
3	1	5

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
    (str,opt)"rsn"  : (str)
}
```

where:

"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
"rsn"	optional string that clarifies reason for an error; specifically useful when `rc` is *MGMT_ERR_EUNKNOWN*.

Note

Response from Zephyr running device may have "rc" value of *MGMT_ERR_EBADSTATE*, which means that the secondary image has been marked for next boot already and may not be erased.

Statistics management Statistics management allows to obtain data gathered by Statistics subsystem of Zephyr, enabled with `CONFIG_STATS`.

Statistics management group defines commands:

Command ID	Command description
0	Group data
1	List groups

Statistics: group data The command is used to obtain data for group specified by a name. The name is one of group names as registered, with `STATS_INIT_AND_REG` macro or `stats_init_and_reg()` function call, within module that gathers the statistics.

Statistics: group data request Statistics group data request header:

OP	Group ID	Command ID
0	2	0

CBOR data of request:

```
{
    (str)"name" :  (str)
}
```

where:

“name”	group name.

Statistics: group data response Statistics group data response header:

OP	Group ID	Command ID
1	2	0

CBOR data of successful response:

```
{
    (str)"name"     : (str)
    (str)"fields"   : {
        (str)<entry_name> : (uint)
        ...
    }
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“name”	this is name of group the response contains data for.
“fields”	this is map of entries within groups that consists of pairs where the entry name is mapped to value it represents in statistics.
<entry_name>	single entry to value mapping; value is hardcoded to unsigned integer type, in a CBOR meaning.
“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Statistics: list of groups The command is used to obtain list of groups of statistics that are gathered on a device. This is a list of names as given to groups with `STATS_INIT_AND_REG` macro or `stats_init_and_reg()` function calls, within module that gathers the statistics; this means that this command may be considered optional as it is known during compilation what groups will be included into build and listing them is not needed prior to issuing a query.

Statistics: list of groups request Statistics group list request header:

OP	Group ID	Command ID
0	2	1

The command sends an empty CBOR map as data.

Statistics: list of groups response Statistics group list request header:

OP	Group ID	Command ID
1	2	1

CBOR data of successful response:

```
{
    (str)"stat_list" :  [
        (str)<stat_group_name>, ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“stat_list”	array of strings representing group names; this array may be empty if there are no groups.
“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Settings (Config) Management Group Settings management group (known as Configuration Manager in the original MCUmgr repository) defines the following commands:

Command ID	Command description
0	Read/write setting
1	Delete setting
2	Commit settings
3	Load/Save settings

Note that the Zephyr version adds additional commands and features which are not supported by the original upstream version, however, the original client functionality should work for read/write functionality.

Read/write setting command Read/write setting command allows updating a setting entry on a device or getting the current value of a setting from a device.

Read setting request Read setting request header fields:

OP	Group ID	Command ID
0	3	0

CBOR data of request:

```
{
    (str)"name"         : (str)
    (str,opt)"max_size" : (uint)
}
```

where:

“name”	string of the setting to retrieve
“max_size”	optional maximum size of data to return

Read setting response Read setting response header fields:

OP	Group ID	Command ID
1	3	0

CBOR data of successful response:

```
{
    (str)"val"          : (bstr)
    (str,opt)"max_size" : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“val”	binary string of the returned data, note that the underlying data type cannot be specified through this and must be known by the client.
“max_s	will be set if the maximum supported data size is smaller than the maximum requested data size, and contains the maximum data size which the device supports, equivalent to kconfig:option:*CONFIG_MCUMGR_GRP_SETTINGS_NAME_LEN*.
“err” -> “group	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Write setting request Write setting request header fields:

OP	Group ID	Command ID
2	3	0

CBOR data of request:

```
{
    (str)"name"    : (str)
    (str)"val"     : (bstr)
}
```

where:

“name”	string of the setting to update/set
“val”	value to set the setting to

Write setting response Write setting response header fields:

OP	Group ID	Command ID
3	3	0

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Delete setting command Delete setting command allows deleting a setting on a device.

Delete setting request Delete setting request header fields:

OP	Group ID	Command ID
2	3	1

CBOR data of request:

```
{
    (str)"name"   : (str)
}
```

where:

“name”	string of the setting to delete

Delete setting response Delete setting response header fields:

OP	Group ID	Command ID
3	3	1

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Commit settings command Commit settings command allows committing all settings that have been set but not yet applied on a device.

Commit settings request Commit settings request header fields:

OP	Group ID	Command ID
2	3	2

The command sends an empty CBOR map as data.

Commit settings response Commit settings response header fields:

OP	Group ID	Command ID
3	3	2

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Load/Save settings command Load/Save settings command allows loading/saving all serialized items from/to persistent storage on a device.

Load settings request Load settings request header fields:

OP	Group ID	Command ID
0	3	3

The command sends an empty CBOR map as data.

Load settings response Load settings response header fields:

OP	Group ID	Command ID
1	3	3

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Save settings request Save settings request header fields:

OP	Group ID	Command ID
2	3	3

The command sends an empty CBOR map as data.

Save settings response Save settings response header fields:

OP	Group ID	Command ID
3	3	3

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Settings access callback There is a settings access MCUmgr callback available (see *MCUmgr Callbacks* for details on callbacks) which allows for applications/modules to know when settings management commands are used and, optionally, block access (for example through the use of a security mechanism). This callback can be enabled with `CONFIG_MCUMGR_GRP_SETTINGS_ACCESS_HOOK`, registered with the event *MGMT_EVT_OP_SETTINGS_MGMT_ACCESS*, whereby the supplied callback data is `settings_mgmt_access`.

File management The file management group provides commands that allow to upload and download files to/from a device.

File management group defines following commands:

Command ID	Command description
0	File download/upload
1	File status
2	File hash/checksum
3	Supported file hash/checksum types
4	File close

File download Command allows to download contents of an existing file from specified path of a target device. Client applications must keep track of data they have already downloaded and where their position in the file is (MCUmgr will cache these also), and issue subsequent requests, with modified offset, to gather the entire file. Request does not carry size of requested chunk, the size is specified by application itself. Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached and another transport does not make use of uploading/downloading files using fs_mgmt), but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed.

Note

By default, all file upload/download requests are unconditionally allowed. However, if the Kconfig option `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` is enabled, then an application can register a callback handler for *MGMT_EVT_OP_FS_MGMT_FILE_ACCESS* (see *MCUmgr callbacks*), which allows for allowing or declining access to reading/writing a particular file, or for rewriting the path supplied by the client.

File download request File download request header:

OP	Group ID	Command ID
0	8	0

CBOR data of request:

```
{
    (str)"off" :  (uint)
    (str)"name" : (str)
}
```

where:

“off”	offset to start download at
“name”	absolute path to a file

File download response File download response header:

OP	Group ID	Command ID
1	8	0

CBOR data of successful response:

```
{
    (str)"off"      : (uint)
    (str)"data"     : (byte str)
    (str,opt)"len"  : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“off”	offset the response is for.
“data”	chunk of data read from file; it is CBOR encoded stream of bytes with embedded size; “data” appears only in responses where “rc” is 0.
“len”	length of file, this field is only mandatory when “off” is 0.
“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File upload Allows to upload a file to a specified location. Command will automatically overwrite existing file or create a new one if it does not exist at specified path. The protocol supports stateless upload where each requests carries different chunk of a file and it is client side responsibility to track progress of upload.

Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached, but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed. Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached and another

transport does not make use of uploading/downloading files using fs_mgmt), but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed.

Note

Weirdly, the current Zephyr implementation is half-stateless as is able to hold single upload context, holding information on ongoing upload, that consists of bool flag indicating in-progress upload, last successfully uploaded offset and total length only.

Note

By default, all file upload/download requests are unconditionally allowed. However, if the Kconfig option `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` is enabled, then an application can register a callback handler for *`MGMT_EVT_OP_FS_MGMT_FILE_ACCESS`* (see *MCUmgr callbacks*), which allows for allowing or declining access to reading/writing a particular file, or for rewriting the path supplied by the client.

File upload request File upload request header:

OP	Group ID	Command ID
2	8	0

CBOR data of request:

```
{
    (str)"off"      : (uint)
    (str)"data"     : (str)
    (str)"name"     : (str)
    (str,opt)"len"  : (uint)
}
```

where:

“off”	offset to start/continue upload at.
“data”	chunk of data to write to the file; it is CBOR encoded with length embedded.
“name”	absolute path to a file.
“len”	length of file, this field is only mandatory when “off” is 0.

File upload response File upload response header:

OP	Group ID	Command ID
3	8	0

CBOR data of successful response:

```
{
    (str)"off"      : (uint)
}
```

In case of error the CBOR data takes the form:

where:

“off”	offset of last successfully written data.
“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File status Command allows to retrieve status of an existing file from specified path of a target device.

File status request File status request header:

OP	Group ID	Command ID
0	8	1

CBOR data of request:

```
{
    (str)"name" : (str)
}
```

where:

“name”	absolute path to a file.

File status response File status response header:

OP	Group ID	Command ID
1	8	1

CBOR data of successful response:

```
{
    (str)"len"      : (uint)
}
```

In case of error the CBOR data takes form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“len”		length of file (in bytes).
“err” “group”	->	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” “rc”	->	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”		*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File hash/checksum Command allows to generate a hash/checksum of an existing file at a specified path on a target device. Note that kernel heap memory is required for buffers to be allocated for this to function, and large stack memory buffers are required for generation of the output hash/checksum. Requires `CONFIG_MCUMGR_GRP_FS_CHECKSUM_HASH` to be enabled for the base functionality, supported hash/checksum are opt-in with `CONFIG_MCUMGR_GRP_FS_CHECKSUM_IEEE_CRC32` or `CONFIG_MCUMGR_GRP_FS_HASH_SHA256`.

File hash/checksum request File hash/checksum request header:

OP	Group ID	Command ID
0	8	2

CBOR data of request:

```
{
    (str)"name"     : (str)
    (str,opt)"type" : (str)
    (str,opt)"off"  : (uint)
    (str,opt)"len"  : (uint)
}
```

where:

“name”	absolute path to a file.
“type”	type of hash/checksum to perform *Hash/checksum types* or omit to use default.
“off”	offset to start hash/checksum calculation at (optional, 0 if not provided).
“len”	maximum length of data to read from file to generate hash/checksum with (optional, full file size if not provided).

Hash/checksum types

String name	Hash/checksum	Byte string	Size (bytes)
crc32	IEEE CRC32 checksum	No	4
sha256	SHA256 (Secure Hash Algorithm)	Yes	32

Note that the default type will be crc32 if it is enabled, or sha256 if crc32 is not enabled.

File hash/checksum response File hash/checksum response header:

OP	Group ID	Command ID
1	8	2

CBOR data of successful response:

```
{
    (str)"type"     : (str)
    (str,opt)"off"  : (uint)
    (str)"len"      : (uint)
    (str)"output"   : (uint or bstr)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"type"	type of hash/checksum that was performed *Hash/checksum types*.
"off"	offset that hash/checksum calculation started at (only present if not 0).
"len"	length of input data used for hash/checksum generation (in bytes).
"output"	output hash/checksum.
"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Supported file hash/checksum types Command allows listing which hash and checksum types are available on a device. Requires Kconfig `CONFIG_MCUMGR_GRP_FS_CHECKSUM_HASH_SUPPORTED_CMD` to be enabled.

Supported file hash/checksum types request Supported file hash/checksum types request header:

OP	Group ID	Command ID
0	8	3

The command sends empty CBOR map as data.

Supported file hash/checksum types response Supported file hash/checksum types response header:

OP	Group ID	Command ID
1	8	3

CBOR data of successful response:

```
{
    (str)"types" : {
        (str)<hash_checksum_name> : {
            (str)"format"       : (uint)
            (str)"size"         : (uint)
        }
        ...
    }
}
```

In case of error the CBOR data takes form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

<hash_checksur	name of the hash/checksum type *Hash/checksum types*.
“format”	format that the hash/checksum returns where 0 is for numerical and 1 is for byte array.
“size”	size (in bytes) of output hash/checksum response.
“err” -> “group”	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File close Command allows closing any open file handles held by fs_mgmt upload/download requests that might have stalled or be incomplete.

File close request File close request header:

OP	Group ID	Command ID
2	8	4

The command sends empty CBOR map as data.

File close response File close response header:

OP	Group ID	Command ID
3	8	4

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Shell management Shell management allows passing commands to the shell subsystem over the SMP protocol.

Shell management group defines following commands:

Command ID	Command description
0	Shell command line execute

Shell command line execute The command allows to execute command line in a similar way to typing it into a shell, but both a request and a response are transported over SMP.

Shell command line execute request Execute command request header:

OP	Group ID	Command ID
2	9	0

CBOR data of request:

```
{
    (str)"argv"     : [
        (str)<cmd>
        (str,opt)<arg>
        ...
    ]
}
```

where:

“argv”	array consisting of strings representing command and its arguments.
<cmd>	command to be executed.
<arg>	optional arguments to command.

Shell command line execute response Command line execute response header fields:

OP	Group ID	Command ID
3	9	0

CBOR data of successful response:

```
{
    (str)"o"            : (str)
    (str)"ret"          : (int)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“o”		command output.
“ret”		return code from shell command execution.
“err” “group”	->	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” “rc”	->	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”		*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Note

In older versions of Zephyr, "rc" was used for both the mcumgr status code and shell command execution return code, this legacy behaviour can be restored by enabling `CONFIG_MCUMGR_GRP_SHELL_LEGACY_RC_RETURN_CODE`

4.5.6 SMP Transport Specification

The documents specifies information needed for implementing server and client side SMP transports.

BLE (Bluetooth Low Energy)

MCUmgr Clients need to use following BLE Characteristics, when implementing SMP client:

- **Service UUID**: *8D53DC1D-1DB7-4CD3-868B-8A527460AA84*
- **Characteristic UUID**: *DA2E7828-FBCE-4E01-AE9E-261174997C48*

All SMP communication utilizes a single GATT characteristic. An SMP request is sent via a GATT Write Without Response command. An SMP response is sent in the form of a GATT Notification

If an SMP request or response is too large to fit in a single GATT command, the sender fragments it across several packets. No additional framing is introduced when a request or response is fragmented; the payload is simply split among several packets. Since GATT guarantees ordered delivery of packets, the SMP header in the first fragment contains sufficient information for reassembly.

UART/serial and console

SMP protocol specification by MCUmgr subsystem of Zephyr uses basic framing of data to allow multiplexing of UART channel. Multiplexing requires prefixing each frame with two byte marker and terminating it with newline. Currently MCUmgr imposes a 127 byte limit on frame size, although there are no real protocol constraints that require that limit. The limit includes the prefix and the newline character, so the allowed payload size is actually 124 bytes.

Although no such transport exists in Zephyr, it is possible to implement MCUmgr client/server over UART transport that does not have framing at all, or uses hardware serial port control, or other means of framing.

Frame fragmenting SMP protocol over serial is fragmented into MTU size frames; each frame consists of two byte start marker, body and terminating newline character.

There are four types of types of frames: initial, partial, partial-final and initial-final; each frame type differs by start marker and/or body contents.

Frame formats Initial frame requires to be followed by optional sequence of partial frames and finally by partial-final frame. Body is always Base64 encoded, so the body size, here described as MTU - 3, is able to actually carry N = (MTU - 3) / 4 * 3 bytes of raw data.

Body of initial frame is preceded by two byte total packet length, encoded in Big Endian, and equals size of a raw body plus two bytes, size of CRC16; this means that actual body size allowed into an initial frame is N - 2.

If a body size is smaller than N - 4, than it is possible to carry entire body with preceding length and following it CRC in a single frame, here called initial-final; for the description of initial-final frame look below.

Initial frame format:

Content	Size	Description
0x06 0x09	2 bytes	Frame start marker
<base64-i>	no more than MTU - 3 bytes	Base64 encoded body
0x0a	1 byte	Frame termination

<base64-i> is Base64 encoded body of format:

Content	Size	Description
total length	2 bytes	Big endian 16-bit value representing total length of body + 2 bytes for CRC16; note that size of total length field is not added to total length value.
body	no more than MTU - 5	Raw body data fragment

Initial-final frame format is similar to initial frame format, but differs by <base64-i> definition.

<base64-i> of initial-final frame, is Base64 encoded data taking form:

Content	Size	Description
total length	2 bytes	Big endian 16-bit value representing total length of body + 2 bytes for CRC16; note that size of total length field is not added to total length value.
body	no more than MTU - 7	Raw body data fragment
crc16	2 bytes	CRC16 of entire packet body, preceding length not included.

Partial frame is continuation after previous initial or other partial frame. Partial frame takes form:

Content	Size	Description
0x04 0x14	2 bytes	Frame start marker
<base64-i>	no more than MTU - 3 bytes	Base64 encoded body
0x0a	1 byte	Frame termination

The <base64-i> of partial frame is Base64 encoding of data, taking form:

Content	Size	Description
body	no more than MTU - 3	Raw body data fragment

The <base64-i> of partial-final frame is Base64 encoding of data, taking form:

Content	Size	Description
body	no more than MTU - 3	Raw body data fragment
crc16	2 bytes	CRC16 of entire packet body, preceding length not included.

CRC Details The CRC16 included in final type frames is calculated over only raw data and does not include packet length. CRC16 polynomial is 0x1021 and initial value is 0.

API Reference

group `mcumgr_transport_smp`

MCUmgr transport SMP API.

Typedefs

typedef int (*`smp_transport_out_fn`)(struct *net_buf* *nb)

SMP transmit callback for transport.

The supplied *net_buf* is always consumed, regardless of return code.

Param nb
The *net_buf* to transmit.

Return
0 on success, *mcumgr_err_t* code on failure.

typedef uint16_t (*`smp_transport_get_mtu_fn`)(const struct *net_buf* *nb)

SMP MTU query callback for transport.

The supplied *net_buf* should contain a request received from the peer whose MTU is being queried. This function takes a *net_buf* parameter because some transports store connection-specific information in the *net_buf* user header (e.g., the BLE transport stores the peer address).

Param nb
Contains a request from the relevant peer.

Return
The transport's MTU; 0 if transmission is currently not possible.

typedef int (*`smp_transport_ud_copy_fn`)(struct *net_buf* *dst, const struct *net_buf* *src)

SMP copy user_data callback.

The supplied src *net_buf* should contain a user_data that cannot be copied using regular memcpy function (e.g., the BLE transport *net_buf* user_data stores the connection reference that has to be incremented when is going to be used by another buffer).

Param dst
Source buffer user_data pointer.

Param src
Destination buffer user_data pointer.

Return
0 on success, *mcumgr_err_t* code on failure.

typedef void (*smp_transport_ud_free_fn)(void *ud)

SMP free user_data callback.

This function frees *net_buf* user data, because some transports store connection-specific information in the *net_buf* user data (e.g., the BLE transport stores the connection reference that has to be decreased).

Param ud
Contains a user_data pointer to be freed.

typedef bool (*smp_transport_query_valid_check_fn)(struct *net_buf* *nb, void *arg)

Function for checking if queued data is still valid.

This function is used to check if queued SMP data is still valid e.g. on a remote device disconnecting, this is triggered when *smp_rx_remove_invalid()* is called.

Param nb
net buf containing queued request.

Param arg
Argument provided when calling *smp_rx_remove_invalid()* function.

Return
false if data is no longer valid/should be freed, true otherwise.

Enums

enum smp_transport_type

SMP transport type for client registration.

Values:

enumerator SMP_SERIAL_TRANSPORT = 0

SMP serial.

enumerator SMP_BLUETOOTH_TRANSPORT

SMP bluetooth.

enumerator SMP_SHELL_TRANSPORT

SMP shell.

enumerator SMP_UDP_IPV4_TRANSPORT

SMP UDP IPv4.

enumerator SMP_UDP_IPV6_TRANSPORT

SMP UDP IPv6.

enumerator SMP_USER_DEFINED_TRANSPORT

SMP user defined type.

Functions

int **smp_transport_init**(struct *smp_transport* *smpt)

Initializes a Zephyr SMP transport object.

Parameters

- **smpt** – The transport to construct.

Returns
0 If successful

Returns
Negative errno code if failure.

void **smp_rx_remove_invalid**(struct *smp_transport* *zst, void *arg)

Used to remove queued requests for an SMP transport that are no longer valid.

A *smp_transport_query_valid_check_fn()* function must be registered for this to function. If the *smp_transport_query_valid_check_fn()* function returns false during a callback, the queried command will classed as invalid and dropped.

Parameters

- **zst** – The transport to use.
- **arg** – Argument provided to callback *smp_transport_query_valid_check_fn()* function.

void **smp_rx_clear**(struct *smp_transport* *zst)

Used to clear pending queued requests for an SMP transport.

Parameters

- **zst** – The transport to use.

void **smp_client_transport_register**(struct *smp_client_transport_entry* *entry)

Register a Zephyr SMP transport object for client.

Parameters

- **entry** – The transport to construct.

struct *smp_transport* ***smp_client_transport_get**(int smpt_type)

Discover a registered SMP transport client object.

Parameters

- **smpt_type** – Type of transport

Returns
Pointer to registered object. Unknown type return NULL.

struct **smp_transport_api_t**

#include <smp.h> Function pointers of SMP transport functions, if a handler is NULL then it is not supported/implemented.

Public Members

smp_transport_out_fn **output**

Transport's send function.

smp_transport_get_mtu_fn **get_mtu**

Transport's get-MTU function.

smp_transport_ud_copy_fn **ud_copy**
Transport buffer user_data copy function.

smp_transport_ud_free_fn **ud_free**
Transport buffer user_data free function.

smp_transport_query_valid_check_fn **query_valid_check**
Transport's check function for if a query is valid.

struct **smp_transport**
#include <*smp.h*> SMP transport object for sending SMP responses.

struct **smp_client_transport_entry**
#include <*smp.h*> SMP Client transport structure.

Public Members

struct *smp_transport* ***smpt**
Transport structure pointer.

int **smpt_type**
Transport type.

4.5.7 Device Firmware Upgrade

Overview

The Device Firmware Upgrade subsystem provides the necessary frameworks to upgrade the image of a Zephyr-based application at run time. It currently consists of two different modules:

- subsys/dfu/boot/: Interface code to bootloaders
- subsys/dfu/img_util/: Image management code

The DFU subsystem deals with image management, but not with the transport or management protocols themselves required to send the image to the target device. For information on these protocols and frameworks please refer to the *Device Management* section.

Flash Image The flash image API as part of the Device Firmware Upgrade (DFU) subsystem provides an abstraction on top of Flash Stream to simplify writing firmware image chunks to flash.

API Reference

group **flash_img_api**
Abstraction layer to write firmware images to flash.

Functions

int **flash_img_init_id**(struct *flash_img_context* *ctx, uint8_t area_id)

Initialize context needed for writing the image to the flash.

Parameters

- **ctx** – context to be initialized
- **area_id** – flash area id of partition where the image should be written

Returns

0 on success, negative errno code on fail

int **flash_img_init**(struct *flash_img_context* *ctx)

Initialize context needed for writing the image to the flash.

Parameters

- **ctx** – context to be initialized

Returns

0 on success, negative errno code on fail

size_t **flash_img_bytes_written**(struct *flash_img_context* *ctx)

Read number of bytes of the image written to the flash.

Parameters

- **ctx** – context

Returns

Number of bytes written to the image flash.

int **flash_img_buffered_write**(struct *flash_img_context* *ctx, const uint8_t *data, size_t len, bool flush)

Process input buffers to be written to the image slot 1.

flash memory in single blocks. Will store remainder between calls.

A final call to this function with flush set to true will write out the remaining block buffer to flash. Since flash is written to in blocks, the contents of flash from the last byte written up to the next multiple of CONFIG_IMG_BLOCK_BUF_SIZE is padded with 0xff.

Parameters

- **ctx** – context
- **data** – data to write
- **len** – Number of bytes to write
- **flush** – when true this forces any buffered data to be written to flash

Returns

0 on success, negative errno code on fail

int **flash_img_check**(struct *flash_img_context* *ctx, const struct *flash_img_check* *fic, uint8_t area_id)

Verify flash memory length bytes integrity from a flash area.

The start point is indicated by an offset value.

The function is enabled via CONFIG_IMG_ENABLE_IMAGE_CHECK Kconfig options.

Parameters

- **ctx** – **[in]** context.

- `fic` – **[in]** flash img check data.
- `area_id` – **[in]** flash area id of partition where the image should be verified.

Returns
0 on success, negative errno code on fail

struct `flash_img_context`

#include <flash_img.h>

struct `flash_img_check`

#include <flash_img.h> Structure for verify flash region integrity.

Match vector length is fixed and depends on size from hash algorithm used to verify flash integrity. The current available algorithm is SHA-256.

Public Members

size_t `clen`

Match vector data.

MCUBoot API The MCUboot API is provided to get version information and boot status of application images. It allows to select application image and boot type for the next boot.

API Reference

group `mcuboot_api`

MCUboot public API for MCUboot control of image boot process.

Defines

`BOOT_SWAP_TYPE_NONE`

Attempt to boot the contents of slot 0.

`BOOT_SWAP_TYPE_TEST`

Swap to slot 1.

Absent a confirm command, revert back on next boot.

`BOOT_SWAP_TYPE_PERM`

Swap to slot 1, and permanently switch to booting its contents.

`BOOT_SWAP_TYPE_REVERT`

Swap back to alternate slot.

A confirm changes this state to NONE.

`BOOT_SWAP_TYPE_FAIL`

Swap failed because image to be run is not valid.

BOOT_IMG_VER_STRLEN_MAX

BOOT_UPGRADE_TEST

Boot upgrade request modes.

BOOT_UPGRADE_PERMANENT

Functions

int **boot_read_bank_header**(uint8_t area_id, struct *mcuboot_img_header* *header, size_t header_size)

Read the MCUboot image header information from an image bank.

This attempts to parse the image header, From the start of the *area_id* image.

Parameters

- **area_id** – *flash_area* ID of image bank which stores the image.
- **header** – On success, the returned header information is available in this structure.
- **header_size** – Size of the header structure passed by the caller. If this is not large enough to contain all of the necessary information, an error is returned.

Returns

Zero on success, a negative value on error.

bool **boot_is_img_confirmed**(void)

Check if the currently running image is confirmed as OK.

MCUboot can perform "test" upgrades. When these occur, a new firmware image is installed and booted, but the old version will be reverted at the next reset unless the new image explicitly marks itself OK.

This routine can be used to check if the currently running image has been marked as OK.

See also

boot_write_img_confirmed()

Returns

True if the image is confirmed as OK, false otherwise.

int **boot_write_img_confirmed**(void)

Marks the currently running image as confirmed.

This routine attempts to mark the currently running firmware image as OK, which will install it permanently, preventing MCUboot from reverting it for an older image at the next reset.

This routine is safe to call if the current image has already been confirmed. It will return a successful result in this case.

Returns

0 on success, negative errno code on fail.

int **boot_write_img_confirmed_multi**(int image_index)

Marks the image with the given index in the primary slot as confirmed.

This routine attempts to mark the firmware image in the primary slot as OK, which will install it permanently, preventing MCUboot from reverting it for an older image at the next reset.

This routine is safe to call if the current image has already been confirmed. It will return a successful result in this case.

Parameters

- **image_index** – Image pair index.

Returns
0 on success, negative errno code on fail.

int **mcuboot_swap_type**(void)

Determines the action, if any, that mcuboot will take on the next reboot.

Returns
a BOOT_SWAP_TYPE_[...] constant on success, negative errno code on fail.

int **mcuboot_swap_type_multi**(int image_index)

Determines the action, if any, that mcuboot will take on the next reboot.

Parameters

- **image_index** – Image pair index.

Returns
a BOOT_SWAP_TYPE_[...] constant on success, negative errno code on fail.

int **boot_request_upgrade**(int permanent)

Marks the image in slot 1 as pending.

On the next reboot, the system will perform a boot of the slot 1 image.

Parameters

- **permanent** – Whether the image should be used permanently or only tested once: BOOT_UPGRADE_TEST=run image once, then confirm or revert. BOOT_UPGRADE_PERMANENT=run image forever.

Returns
0 on success, negative errno code on fail.

int **boot_request_upgrade_multi**(int image_index, int permanent)

Marks the image with the given index in the secondary slot as pending.

On the next reboot, the system will perform a boot of the secondary slot image.

Parameters

- **image_index** – Image pair index.
- **permanent** – Whether the image should be used permanently or only tested once: BOOT_UPGRADE_TEST=run image once, then confirm or revert. BOOT_UPGRADE_PERMANENT=run image forever.

Returns
0 on success, negative errno code on fail.

int **boot_erase_img_bank**(uint8_t area_id)

Erase the image Bank.

Parameters

- **area_id** – *flash_area* ID of image bank to be erased.

Returns
0 on success, negative errno code on fail.

ssize_t **boot_get_area_trailer_status_offset**(uint8_t area_id)

Get the offset of the status in the image bank.

Parameters

- **area_id** – *flash_area* ID of image bank to get the status offset

Returns
a positive offset on success, negative errno code on fail

ssize_t **boot_get_trailer_status_offset**(size_t area_size)

Get the offset of the status from an image bank size.

Parameters

- **area_size** – size of image bank

Returns
offset of the status. When negative the status will not fit the given size

struct **mcuboot_img_sem_ver**

#include <*mcuboot.h*> MCUboot image header representation for image version.

The header for an MCUboot firmware image contains an embedded version number, in semantic versioning format. This structure represents the information it contains.

struct **mcuboot_img_header_v1**

#include <*mcuboot.h*> Model for the MCUboot image header as of version 1.

This represents the data present in the image header, in version 1 of the header format.

Some information present in the header but not currently relevant to applications is omitted.

Public Members

uint32_t **image_size**

The size of the image, in bytes.

struct *mcuboot_img_sem_ver* **sem_ver**

The image version.

struct **mcuboot_img_header**

#include <*mcuboot.h*> Model for the MCUBoot image header.

This contains the decoded image header, along with the major version of MCUboot that the header was built for.

(The MCUboot project guarantees that incompatible changes to the image header will result in major version changes to the bootloader itself, and will be detectable in the persistent representation of the header.)

Public Members

uint32_t **mcuboot_version**

The version of MCUboot the header is built for.

The value 1 corresponds to MCUboot versions 1.x.y.

struct *mcuboot_img_header_v1* **v1**

Header information for MCUboot version 1.

union *mcuboot_img_header* **h**

The header information.

It is only valid to access fields in the union member corresponding to the mcuboot_version field above.

Bootloaders

MCUboot Zephyr is directly compatible with the open source, cross-RTOS MCUboot boot loader. It interfaces with MCUboot and is aware of the image format required by it, so that Device Firmware Upgrade is available when MCUboot is the boot loader used with Zephyr. The source code itself is hosted in the MCUboot GitHub Project page.

In order to use MCUboot with Zephyr you need to take the following into account:

1. You will need to define the flash partitions required by MCUboot; see *Flash map* for details.
2. You will have to specify your flash partition as the chosen code partition

```
/ {
   chosen {
      zephyr,code-partition = &slot0_partition;
   };
};
```

3. Your application's `.conf` file needs to enable the `CONFIG_BOOTLOADER_MCUBOOT` Kconfig option in order for Zephyr to be built in an MCUboot-compatible manner
4. You need to build and flash MCUboot itself on your device
5. You might need to take precautions to avoid mass erasing the flash and also to flash the Zephyr application image at the correct offset (right after the bootloader)

More detailed information regarding the use of MCUboot with Zephyr can be found in the MCUboot with Zephyr documentation page on the MCUboot website.

4.5.8 Over-the-Air Update

Overview

Over-the-Air (OTA) Update is a method for delivering firmware updates to remote devices using a network connection. Although the name implies a wireless connection, updates received over a wired connection (such as Ethernet) are still commonly referred to as OTA updates. This approach requires server infrastructure to host the firmware binary and implement a method of signaling when an update is available. Security is a concern with OTA updates; firmware binaries should be cryptographically signed and verified before upgrading.

The *Device Firmware Upgrade* section discusses upgrading Zephyr firmware using MCUboot. The same method can be used as part of OTA. The binary is first downloaded into an unoccupied code partition, usually named `slot1_partition`, then upgraded using the *MCUboot* process.

Examples of OTA

Golioth Golioth is an IoT management platform that includes OTA updates. Devices are configured to observe your available firmware revisions on the Golioth Cloud. When a new version is available, the device downloads and flashes the binary. In this implementation, the connection between cloud and device is secured using TLS/DTLS, and the signed firmware binary is confirmed by MCUboot before the upgrade occurs.

1. A working sample can be found on the Golioth Firmware SDK repository
2. The Golioth OTA documentation includes complete information about the versioning process

Eclipse hawkBit™ Eclipse hawkBit™ is an update server framework that uses polling on a REST api to detect firmware updates. When a new update is detected, the binary is downloaded and installed. MCUboot can be used to verify the signature before upgrading the firmware.

There is a hawkbit-api sample included in the Zephyr mgmt-samples section.

UpdateHub UpdateHub is a platform for remotely updating embedded devices. Updates can be manually triggered or monitored via polling. When a new update is detected, the binary is downloaded and installed. MCUboot can be used to verify the signature before upgrading the firmware.

There is an updatehub-fota sample included in the Zephyr mgmt-samples section.

SMP Server A Simple Management Protocol (SMP) server can be used to update firmware via Bluetooth Low Energy (BLE) or UDP. *MCUmgr* is used to send a signed firmware binary to the remote device where it is verified by MCUboot before the upgrade occurs.

There is an smp-svr sample included in the Zephyr mgmt-samples section.

Lightweight M2M (LWM2M) The *Lightweight M2M (LWM2M)* protocol includes support for firmware update via `CONFIG_LWM2M_FIRMWARE_UPDATE_OBJ_SUPPORT`. Devices securely connect to an LwM2M server using DTLS. A lwm2m-client sample is available but it does not demonstrate the firmware update feature.

4.5.9 EC Host Command

Overview

The host command protocol defines the interface for a host, or application processor, to communicate with a target embedded controller (EC). The EC Host command subsystem implements the target side of the protocol, generating responses to commands sent by the host. The host command protocol interface supports multiple versions, but this subsystem implementation only support protocol version 3.

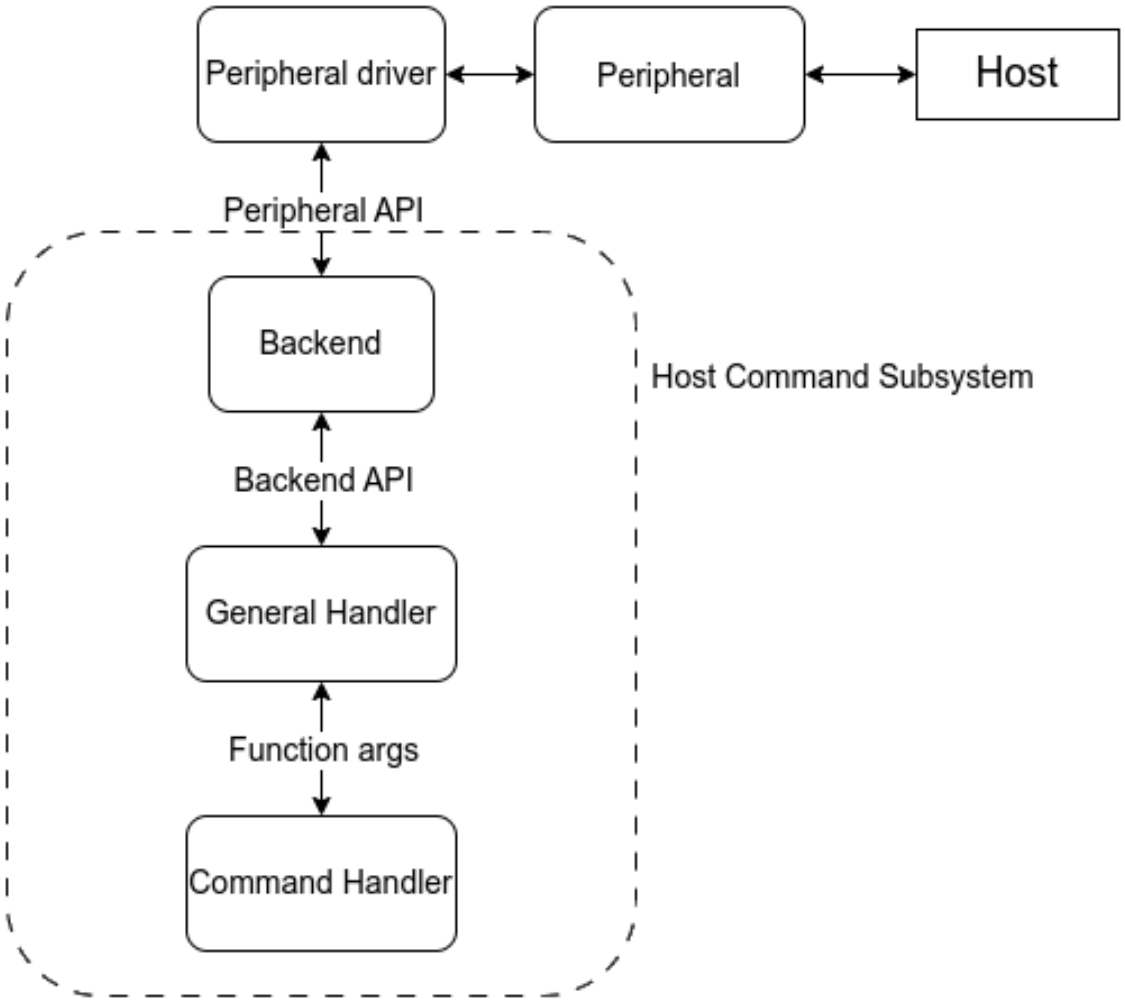
Architecture

The Host Command subsystem contains a few components:

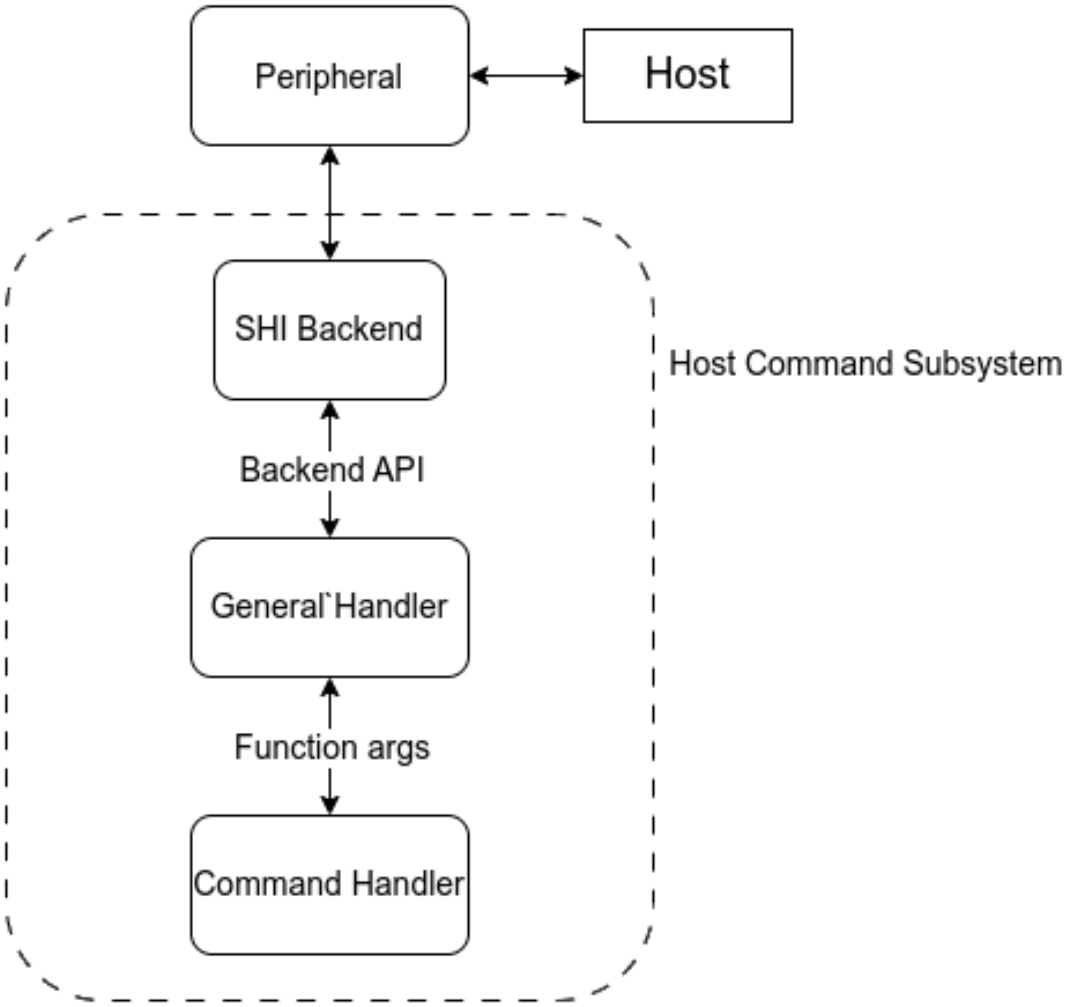
- Backend
- General handler
- Command handler

The backend is a layer between a peripheral driver and the general handler. It is responsible for sending and receiving commands via chosen peripheral.

The general handler validates data from the backend e.g. check sizes, checksum, etc. If the command is valid and the user has provided a handler for a received command id, the command handler is called.



SHI (Serial Host Interface) is different to this because it is used only for communication with a host. SHI does not have API itself, thus the backend and peripheral driver layers are combined into one backend layer.



Another case is SPI. Unfortunately, the current SPI API can't be used to handle the host commands communication. The main issues are unknown command size sent by the host (the SPI transaction sends/receives specific number of bytes) and need to constant sending status byte (the SPI module is enabled and disabled per transaction). It forces implementing the SPI driver within a backend, as it is done for SHI. That means a SPI backend has to be implemented per chip family. However, it can be changed in the future once the SPI API is extended to host command needs. Please check the discussion.

That approach requires configuring the SPI dts node in a special way. The main compatible string of a SPI node has changed to use the Host Command version of a SPI driver. The rest of the properties should be configured as usual. Example of the SPI node for STM32:

```
&spi1 {
        /* Change the compatible string to use the Host Command version of the
         * STM32 SPI driver
         */
        compatible = "st,stm32-spi-host-cmd";
        status = "okay";

        dmas = <&dma2 3 3 0x38440 0x03>,
             <&dma2 0 3 0x38480 0x03>;
        dma-names = "tx", "rx";
        /* This field is used to point at our CS pin */
        cs-gpios = <&gpioa 4 (GPIO_ACTIVE_LOW | GPIO_PULL_UP)>;
};
```

The STM32 SPI host command backend driver supports the `st,stm32h7-spi` and `st,stm32-spi-fifo` variant implementations. To enable these variants, append the corresponding compatible string. For example, to enable FIFO support and support for the STM32H7 SoCs, modify the compatible string as shown.

```
&spi1 {
    compatible = "st,stm32h7-spi", "st,stm32-spi-fifo", "st,stm32-spi-host-cmd";
    ...
};
```

The chip that runs Zephyr is a SPI slave and the *cs-gpios* property is used to point our CS pin. For the SPI, it is required to set the backend chosen node `zephyr,host-cmd-spi-backend`.

The supported backend and peripheral drivers:

- Simulator
- SHI - ITE and NPCX
- eSPI - any eSPI slave driver that support `CONFIG_ESPI_PERIPHERAL_EC_HOST_CMD` and `CONFIG_ESPI_PERIPHERAL_CUSTOM_OPCODE`
- UART - any UART driver that supports the asynchronous API
- SPI - STM32

Initialization

If the application configures one of the following backend chosen nodes and `CONFIG_EC_HOST_CMD_INITIALIZE_AT_BOOT` is set, then the corresponding backend initializes the host command subsystem by calling *ec_host_cmd_init()*:

- `zephyr,host-cmd-espi-backend`
- `zephyr,host-cmd-shi-backend`
- `zephyr,host-cmd-uart-backend`
- `zephyr,host-cmd-spi-backend`

If no backend chosen node is configured, the application must call the *ec_host_cmd_init()* function directly. This way of initialization is useful if a backend is chosen in runtime based on e.g. GPIO state.

Buffers

The host command communication requires buffers for rx and tx. The buffers are be provided by the general handler if `CONFIG_EC_HOST_CMD_HANDLER_RX_BUFFER_SIZE` > 0 for rx buffer and `CONFIG_EC_HOST_CMD_HANDLER_TX_BUFFER_SIZE` > 0 for the tx buffer. The shared buffers are useful for applications that use multiple backends. Defining separate buffers by every backend would increase the memory usage. However, some buffers can be defined by a peripheral driver e.g. eSPI. These ones should be reused as much as possible.

Logging

The host command has an embedded logging system of the ongoing communication. The are a few logging levels:

- *LOG_INF* is used to log a command id of a new command and not success responses. Repeats of the same command are not logged
- *LOG_DBG* logs every command, even repeats

- *LOG_DBG* + CONFIG_EC_HOST_CMD_LOG_DBG_BUFFERS logs every command and responses with the data buffers

API Reference

group **ec_host_cmd_interface**

EC Host Command Interface.

Since
2.4

Version
0.1.0

Defines

EC_HOST_CMD_HANDLER(_id, _function, _version_mask, _request_type, _response_type)

Statically define and register a host command handler.

Helper macro to statically define and register a host command handler that has a compile-time-fixed sizes for its both request and response structures.

Parameters

- **_id** – Id of host command to handle request for.
- **_function** – Name of handler function.
- **_version_mask** – The bitfield of all versions that the *_function* supports. E.g. *BIT(0)* corresponds to version 0.
- **_request_type** – The datatype of the request parameters for *_function*.
- **_response_type** – The datatype of the response parameters for *_function*.

EC_HOST_CMD_HANDLER_UNBOUND(_id, _function, _version_mask)

Statically define and register a host command handler without sizes.

Helper macro to statically define and register a host command handler whose request or response structure size is not known as compile time.

Parameters

- **_id** – Id of host command to handle request for.
- **_function** – Name of handler function.
- **_version_mask** – The bitfield of all versions that the *_function* supports. E.g. *BIT(0)* corresponds to version 0.

Typedefs

typedef int (***ec_host_cmd_backend_api_init**)(const struct ec_host_cmd_backend *backend, struct *ec_host_cmd_rx_ctx* *rx_ctx, struct *ec_host_cmd_tx_buf* *tx)

Initialize a host command backend.

This routine initializes a host command backend. It includes initialization a device used to communication and setting up buffers. This function is called by the ec_host_cmd_init function.

Param backend
[in] Pointer to the backend structure for the driver instance.

Param rx_ctx
[inout] Pointer to the receive context object. These objects are used to receive data from the driver when the host sends data. The buf member can be assigned by the backend.

Param tx
[inout] Pointer to the transmit buffer object. The buf and len_max members can be assigned by the backend. These objects are used to send data by the backend with the ec_host_cmd_backend_api_send function.

Retval 0
if successful

typedef int (***ec_host_cmd_backend_api_send**)(const struct ec_host_cmd_backend *backend)

Sends data to the host.

Sends data from tx buf that was passed via ec_host_cmd_backend_api_init function.

Param backend
Pointer to the backed to send data.

Retval 0
if successful.

typedef void (***ec_host_cmd_user_cb_t**)(const struct *ec_host_cmd_rx_ctx* *rx_ctx, void *user_data)

typedef enum *ec_host_cmd_status* (***ec_host_cmd_in_progress_cb_t**)(void *user_data)

typedef enum *ec_host_cmd_status* (***ec_host_cmd_handler_cb**)(struct *ec_host_cmd_handler_args* *args)

Enums

enum **ec_host_cmd_status**

Host command response codes (16-bit).

Values:

enumerator **EC_HOST_CMD_SUCCESS** = 0

Host command was successful.

enumerator **EC_HOST_CMD_INVALID_COMMAND** = 1

The specified command id is not recognized or supported.

enumerator **EC_HOST_CMD_ERROR** = 2

Generic Error.

enumerator **EC_HOST_CMD_INVALID_PARAM** = 3

One of more of the input request parameters is invalid.

enumerator EC_HOST_CMD_ACCESS_DENIED = 4
Host command is not permitted.

enumerator EC_HOST_CMD_INVALID_RESPONSE = 5
Response was invalid (e.g.
not version 3 of header).

enumerator EC_HOST_CMD_INVALID_VERSION = 6
Host command id version unsupported.

enumerator EC_HOST_CMD_INVALID_CHECKSUM = 7
Checksum did not match.

enumerator EC_HOST_CMD_IN_PROGRESS = 8
A host command is currently being processed.

enumerator EC_HOST_CMD_UNAVAILABLE = 9
Requested information is currently unavailable.

enumerator EC_HOST_CMD_TIMEOUT = 10
Timeout during processing.

enumerator EC_HOST_CMD_OVERFLOW = 11
Data or table overflow.

enumerator EC_HOST_CMD_INVALID_HEADER = 12
Header is invalid or unsupported (e.g.
not version 3 of header).

enumerator EC_HOST_CMD_REQUEST_TRUNCATED = 13
Did not receive all expected request data.

enumerator EC_HOST_CMD_RESPONSE_TOO_BIG = 14
Response was too big to send within one response packet.

enumerator EC_HOST_CMD_BUS_ERROR = 15
Error on underlying communication bus.

enumerator EC_HOST_CMD_BUSY = 16
System busy.
Should retry later.

enumerator EC_HOST_CMD_INVALID_HEADER_VERSION = 17
Header version invalid.

enumerator EC_HOST_CMD_INVALID_HEADER_CRC = 18
Header CRC invalid.

enumerator EC_HOST_CMD_INVALID_DATA_CRC = 19
Data CRC invalid.

enumerator EC_HOST_CMD_DUP_UNAVAILABLE = 20
Can't resend response.

enumerator EC_HOST_CMD_MAX = UINT16_MAX

enum ec_host_cmd_log_level
Values:

enumerator EC_HOST_CMD_DEBUG_OFF

enumerator EC_HOST_CMD_DEBUG_NORMAL

enumerator EC_HOST_CMD_DEBUG_EVERY

enumerator EC_HOST_CMD_DEBUG_PARAMS

enumerator EC_HOST_CMD_DEBUG_MODES

enum ec_host_cmd_state
Values:

enumerator EC_HOST_CMD_STATE_DISABLED = 0

enumerator EC_HOST_CMD_STATE_RECEIVING

enumerator EC_HOST_CMD_STATE_PROCESSING

enumerator EC_HOST_CMD_STATE_SENDING

Functions

struct ec_host_cmd_backend *ec_host_cmd_backend_get_espi(const struct *device* *dev)
Get the eSPI Host Command backend pointer.

Get the eSPI pointer backend and pass a pointer to eSPI device instance that will be used for the Host Command communication.

Parameters

- dev – Pointer to eSPI device instance.

Return values
The – eSPI backend pointer.

struct ec_host_cmd_backend *ec_host_cmd_backend_get_shi_npcx(void)
Get the SHI NPCX Host Command backend pointer.

Return values
the – SHI NPCX backend pointer

struct ec_host_cmd_backend *ec_host_cmd_backend_get_shi_ite(void)

Get the SHI ITE Host Command backend pointer.

Return values

the – SHI ITE backend pointer

struct ec_host_cmd_backend *ec_host_cmd_backend_get_uart(const struct *device* *dev)

Get the UART Host Command backend pointer.

Get the UART pointer backend and pass a pointer to UART device instance that will be used for the Host Command communication.

Parameters

- dev – Pointer to UART device instance.

Return values

The – UART backend pointer.

struct ec_host_cmd_backend *ec_host_cmd_backend_get_spi(struct *gpio_dt_spec* *cs)

Get the SPI Host Command backend pointer.

Get the SPI pointer backend and pass a chip select pin that will be used for the Host Command communication.

Parameters

- cs – Chip select pin..

Return values

The – SPI backend pointer.

int ec_host_cmd_init(struct ec_host_cmd_backend *backend)

Initialize the host command subsystem.

This routine initializes the host command subsystem. It includes initialization of a backend and the handler. When the application configures the zephyr,host-cmd-espi-backend/zephyr,host-cmd-shi-backend/ zephyr,host-cmd-uart-backend chosen node and CONFIG_EC_HOST_CMD_INITIALIZE_AT_BOOT is set, the chosen backend automatically calls this routine at CONFIG_EC_HOST_CMD_INIT_PRIORITY . Applications that require a run-time selection of the backend must set CONFIG_EC_HOST_CMD_INITIALIZE_AT_BOOT to n and must explicitly call this routine.

Parameters

- backend – **[in]** Pointer to the backend structure to initialize.

Return values

0 – if successful

int ec_host_cmd_send_response(enum *ec_host_cmd_status* status, const struct *ec_host_cmd_handler_args* *args)

Send the host command response.

This routine sends the host command response. It should be used to send IN_PROGRESS status or if the host command handler doesn't return e.g. reboot command.

Parameters

- status – **[in]** Host command status to be sent.
- args – **[in]** Pointer of a structure passed to the handler.

Return values

0 – if successful.

void **ec_host_cmd_rx_notify**(void)

Signal a new host command.

Signal that a new host command has been received. The function should be called by a backend after copying data to the rx buffer and setting the length.

void **ec_host_cmd_set_user_cb**(*ec_host_cmd_user_cb_t* cb, void *user_data)

Install a user callback for receiving a host command.

It allows installing a custom procedure needed by a user after receiving a command.

Parameters

- **cb** – **[in]** A callback to be installed.
- **user_data** – **[in]** User data to be passed to the callback.

const struct *ec_host_cmd* ***ec_host_cmd_get_hc**(void)

Get the main ec host command structure.

This routine returns a pointer to the main host command structure. It allows the application code to get inside information for any reason e.g. the host command thread id.

Return values

A – pointer to the main host command structure

FUNC_NORETURN void **ec_host_cmd_task**(void)

The thread function for Host Command subsystem.

This routine calls the Host Command thread entry function. If CONFIG_EC_HOST_CMD_DEDICATED_THREAD is not defined, a new thread is not created, and this function has to be called by application code. It doesn't return.

int **ec_host_cmd_add_suppressed**(uint16_t cmd_id)

Add a suppressed command.

Suppressed commands are not logged. Add a command to be suppressed.

Parameters

- **cmd_id** – **[in]** A command id to be suppressed.

Return values

0 – if successful, -EIO if exceeded max number of suppressed commands.

struct **ec_host_cmd_rx_ctx**

#include <backend.h> Context for host command backend and handler to pass rx data.

Public Members

uint8_t ***buf**

Buffer to hold received data.

The buffer is provided by the handler if CONFIG_EC_HOST_CMD_HANDLER_RX_BUFFER_SIZE > 0. Otherwise, the backend should provide the buffer on its own and overwrites *buf* pointer and *len_max* in the init function.

size_t **len**

Number of bytes written to *buf* by backend.

size_t **len_max**

Maximum number of bytes to receive with one request packet.

struct **ec_host_cmd_tx_buf**

#include <backend.h> Context for host command backend and handler to pass tx data.

Public Members

void ***buf**

Data to write to the host The buffer is provided by the handler if CONFIG_EC_HOST_CMD_HANDLER_TX_BUFFER_SIZE > 0.

Otherwise, the backend should provide the buffer on its own and overwrites *buf* pointer and *len_max* in the init function.

size_t **len**

Number of bytes to write from *buf*.

size_t **len_max**

Maximum number of bytes to send with one response packet.

struct **ec_host_cmd_backend_api**

#include <backend.h>

struct **ec_host_cmd**

#include <ec_host_cmd.h>

Public Members

struct k_sem **rx_ready**

The backend gives rx_ready (by calling the ec_host_cmd_send_receive function), when data in rx_ctx are ready.

The handler takes rx_ready to read data in rx_ctx.

enum *ec_host_cmd_status* **rx_status**

Status of the rx data checked in the ec_host_cmd_send_received function.

ec_host_cmd_user_cb_t **user_cb**

User callback after receiving a command.

It is called by the ec_host_cmd_send_received function.

struct **ec_host_cmd_handler_args**

#include <ec_host_cmd.h> Arguments passed into every installed host command handler.

Public Members

void *reserved

Reserved for compatibility.

uint16_t command

Command identifier.

uint8_t version

The version of the host command that is being requested.

This will be a value that has been static registered as valid for the handler.

const void *input_buf

The incoming data that can be cast to the handlers request type.

uint16_t input_buf_size

The number of valid bytes that can be read from *input_buf*.

void *output_buf

The data written to this buffer will be send to the host.

uint16_t output_buf_max

Maximum number of bytes that can be written to the *output_buf*.

uint16_t output_buf_size

Number of bytes of *output_buf* to send to the host.

struct ec_host_cmd_handler

#include <ec_host_cmd.h> Structure use for statically registering host command handlers.

Public Members

ec_host_cmd_handler_cb handler

Callback routine to process commands that match *id*.

uint16_t id

The numerical command id used as the lookup for commands.

uint16_t version_mask

The bitfield of all versions that the *handler* supports, where each bit value represents that the *handler* supports that version.

E.g. *BIT(0)* corresponds to version 0.

uint16_t min_rqt_size

The minimum *input_buf_size* enforced by the framework before passing to the handler.

uint16_t **min_rsp_size**

The minimum *output_buf_size* enforced by the framework before passing to the handler.

struct **ec_host_cmd_request_header**

#include <ec_host_cmd.h> Header for requests from host to embedded controller.

Represent the over-the-wire header in LE format for host command requests. This represent version 3 of the host command header. The requests are always sent from host to embedded controller.

Public Members

uint8_t **prtcl_ver**

Should be 3.

The EC will return EC_HOST_CMD_INVALID_HEADER if it receives a header with a version it doesn't know how to parse.

uint8_t **checksum**

Checksum of response and data; sum of all bytes including checksum.

Should total to 0.

uint16_t **cmd_id**

Id of command that is being sent.

uint8_t **cmd_ver**

Version of the specific *cmd_id* being requested.

Valid versions start at 0.

uint8_t **reserved**

Unused byte in current protocol version; set to 0.

uint16_t **data_len**

Length of data which follows this header.

struct **ec_host_cmd_response_header**

#include <ec_host_cmd.h> Header for responses from embedded controller to host.

Represent the over-the-wire header in LE format for host command responses. This represent version 3 of the host command header. Responses are always sent from embedded controller to host.

Public Members

uint8_t **prtcl_ver**

Should be 3.

uint8_t **checksum**

Checksum of response and data; sum of all bytes including checksum.

Should total to 0.

uint16_t **result**

A *ec_host_cmd_status* response code for specific command.

uint16_t **data_len**

Length of data which follows this header.

uint16_t **reserved**

Unused bytes in current protocol version; set to 0.

4.5.10 SMP Groups

Zephyr Management Group

Zephyr management group defines the following commands:

Command ID	Command description
0	Erase storage

Erase storage command Erase storage command allows clearing the `storage_partition` flash partition on a device, generally this is used when switching to a new application build if the application uses storage that should be cleared (application dependent).

Erase storage request Erase storage request header fields:

OP	Group ID	Command ID
2	63	0

The command sends sends empty CBOR map as data.

Erase storage response Read setting response header fields:

OP	Group ID	Command ID
3	63	0

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	*mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	*mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

4.6 Digital Signal Processing (DSP)

- *Using zDSP*
- *Optimizing for your architecture*
- *API Reference*

The DSP API provides an architecture agnostic way for signal processing. Currently, the API will work on any architecture but will likely not be optimized. The status of the various architectures can be found below:

Architecture	Status
ARC	Optimized
ARM	Optimized
ARM64	Optimized
MIPS	Unoptimized
NIOS2	Unoptimized
POSIX	Unoptimized
RISCV	Unoptimized
RISCV64	Unoptimized
SPARC	Unoptimized
X86	Unoptimized
XTENSA	Unoptimized

4.6.1 Using zDSP

zDSP provides various backend options which are selected automatically for the application. By default, including the CMSIS module will enable all architectures to use the zDSP APIs. This can

be done by setting:

```
CONFIG_CMSIS_DSP=y
```

If your application requires some additional customization, it's possible to enable `CONFIG_DSP_BACKEND_CUSTOM` which means that the application is responsible for providing the implementation of the zDSP library.

4.6.2 Optimizing for your architecture

If your architecture is showing as `Unoptimized`, it's possible to add a new zDSP backend to better support it. To do that, a new Kconfig option should be added to `subsys/dsp/Kconfig` along with the required dependencies and the `default` set for `DSP_BACKEND` Kconfig choice.

Next, the implementation should be added at `subsys/dsp/<backend>/` and linked in at `subsys/dsp/CMakeLists.txt`. To add architecture-specific attributes, its corresponding Kconfig option should be added to `subsys/dsp/Kconfig` and use them to update `DSP_DATA` and `DSP_STATIC_DATA` in `include/zephyr/dsp/dsp.h`.

4.6.3 API Reference

group **math_dsp**

DSP Interface.

Typedefs

typedef int8_t **q7_t**

8-bit fractional data type in 1.7 format.

typedef int16_t **q15_t**

16-bit fractional data type in 1.15 format.

typedef int32_t **q31_t**

32-bit fractional data type in 1.31 format.

typedef int64_t **q63_t**

64-bit fractional data type in 1.63 format.

typedef __fp16 **float16_t**

16-bit floating point type definition.

typedef float **float32_t**

32-bit floating-point type definition.

typedef double **float64_t**

64-bit floating-point type definition.

4.7 File Systems

Zephyr RTOS Virtual Filesystem Switch (VFS) allows applications to mount multiple file systems at different mount points (e.g., `/fatfs` and `/lfs`). The mount point data structure contains all the necessary information required to instantiate, mount, and operate on a file system. The File system Switch decouples the applications from directly accessing an individual file system's specific API or internal functions by introducing file system registration mechanisms.

In Zephyr, any file system implementation or library can be plugged into or pulled out through a file system registration API. Each file system implementation must have a globally unique integer identifier; use `FS_TYPE_EXTERNAL_BASE` to avoid clashes with in-tree identifiers.

```
int fs_register(int type, const struct fs_file_system_t *fs);

int fs_unregister(int type, const struct fs_file_system_t *fs);
```

Zephyr RTOS supports multiple instances of a file system by making use of the mount point as the disk volume name, which is used by the file system library while formatting or mounting a disk.

A file system is declared as:

```
static struct fs_mount_t mp = {
.type = FS_FATFS,
.mnt_point = FATFS_MNTP,
.fs_data = &fat_fs,
};
```

where

- `FS_FATFS` is the file system type like FATFS or LittleFS.
- `FATFS_MNTP` is the mount point where the file system will be mounted.
- `fat_fs` is the file system data which will be used by fs_mount() API.

4.7.1 Samples

Samples for the VFS are mainly supplied in `samples/subsys/fs`, although various examples of the VFS usage are provided as important functionalities in samples for different subsystems. Here is the list of samples worth looking at:

- `samples/subsys/fs/fat_fs` is an example of FAT file system usage with SDHC media;
- **`samples/subsys/shell/fs` is an example of Shell fs subsystem, using internal flash partition**
  formatted to LittleFS;
- **`samples/subsys/usb/mass/` example of USB Mass Storage device that uses FAT FS driver with RAM**
  or SPI connected FLASH, or LittleFS in flash, depending on the sample configuration.

4.7.2 API Reference

Related code samples

File system manipulation
Use file system API with various filesystems and storage devices.

File system shell
Access a LittleFS file system partition in flash using the file system shell.

Format filesystem
Format different storage devices for different file systems.

LittleFS filesystem
Use file system API over LittleFS.

USB Mass Storage
Expose board's RAM or FLASH as a USB disk using USB Mass Storage driver.

group `file_system_api`

File System APIs.

Since
1.5

Version
1.0.0

fs_open open and creation mode flags

`FS_O_READ`
Open for read flag.

`FS_O_WRITE`
Open for write flag.

`FS_O_RDWR`
Open for read-write flag combination.

`FS_O_MODE_MASK`
Bitmask for read and write flags.

`FS_O_CREATE`
Create file if it does not exist.

`FS_O_APPEND`
Open/create file for append.

`FS_O_TRUNC`
Truncate the file while opening.

FS_O_FLAGS_MASK
: Bitmask for open/create flags.

FS_O_MASK
: Bitmask for open flags.

fs_seek whence parameter values

FS_SEEK_SET
: Seek from the beginning of file.

FS_SEEK_CUR
: Seek from a current position.

FS_SEEK_END
: Seek from the end of file.

Defines

FS_MOUNT_FLAG_NO_FORMAT
: Flag prevents formatting device if requested file system not found.

FS_MOUNT_FLAG_READ_ONLY
: Flag makes mounted file system read-only.

FS_MOUNT_FLAG_AUTOMOUNT
: Flag used in pre-defined mount structures that are to be mounted on startup.

  This flag has no impact in user-defined mount structures.

FS_MOUNT_FLAG_USE_DISK_ACCESS
: Flag requests file system driver to use Disk Access API.

  When the flag is set to the *fs_mount_t.flags* prior to fs_mount call, a file system needs to use the Disk Access API, otherwise mount callback for the driver should return -ENOSUP; when the flag is not set the file system driver should use Flash API by default, unless it only supports Disc Access API. When file system will use Disk Access API and the flag is not set, the mount callback for the file system should set the flag on success.

FSTAB_ENTRY_DT_MOUNT_FLAGS(node_id)
: Get the common mount flags for an fstab entry.

  Parameters

  - **node_id** – the node identifier for a child entry in a zephyr,fstab node.

  Returns
  a value suitable for initializing an *fs_mount_t* flags member.

FS_FSTAB_ENTRY(node_id)
: The name under which a zephyr,fstab entry mount structure is defined.

  Parameters

- **node_id** – the node identifier for a child entry in a zephyr,fstab node.

FS_FSTAB_DECLARE_ENTRY(node_id)

Generate a declaration for the externally defined fstab entry.

This will evaluate to the name of a struct *fs_mount_t* object.

Parameters

- **node_id** – the node identifier for a child entry in a zephyr,fstab node.

Enums

enum **fs_dir_entry_type**

Enumeration for directory entry types.

Values:

enumerator **FS_DIR_ENTRY_FILE** = 0

Identifier for file entry.

enumerator **FS_DIR_ENTRY_DIR**

Identifier for directory entry.

Enumeration to uniquely identify file system types.

Zephyr supports in-tree file systems and external ones. Each requires a unique identifier used to register the file system implementation and to associate a mount point with the file system type. This anonymous enum defines global identifiers for the in-tree file systems.

External file systems should be registered using unique identifiers starting at FS_TYPE_EXTERNAL_BASE. It is the responsibility of applications that use external file systems to ensure that these identifiers are unique if multiple file system implementations are used by the application.

Values:

enumerator **FS_FATFS** = 0

Identifier for in-tree FatFS file system.

enumerator **FS_LITTLEFS**

Identifier for in-tree LittleFS file system.

enumerator **FS_EXT2**

Identifier for in-tree Ext2 file system.

enumerator **FS_TYPE_EXTERNAL_BASE**

Base identifier for external file systems.

Functions

static inline void **fs_file_t_init**(struct *fs_file_t* *zfp)

Initialize *fs_file_t* object.

Initializes the *fs_file_t* object; the function needs to be invoked on object before first use with fs_open.

Parameters

- **zfp** – Pointer to file object

static inline void **fs_dir_t_init**(struct *fs_dir_t* *zdp)

Initialize *fs_dir_t* object.

Initializes the *fs_dir_t* object; the function needs to be invoked on object before first use with fs_opendir.

Parameters

- **zdp** – Pointer to file object

int **fs_open**(struct *fs_file_t* *zfp, const char *file_name, fs_mode_t flags)

Open or create file.

Opens or possibly creates a file and associates a stream with it. Successfully opened file, when no longer in use, should be closed with *fs_close()*.

`flags` can be 0 or a binary combination of one or more of the following identifiers:

- `FS_O_READ` open for read
- `FS_O_WRITE` open for write
- `FS_O_RDWR` open for read/write (`FS_O_READ | FS_O_WRITE`)
- `FS_O_CREATE` create file if it does not exist
- `FS_O_APPEND` move to end of file before each write
- `FS_O_TRUNC` truncate the file

Warning

If `flags` are set to 0 the function will open file, if it exists and is accessible, but you will have no read/write access to it.

Parameters

- **zfp** – Pointer to a file object
- **file_name** – The name of a file to open
- **flags** – The mode flags

Return values

- **0** – on success;
- **-EBUSY** – when zfp is already used;
- **-EINVAL** – when a bad file name is given;
- **-EROFS** – when opening read-only file for write, or attempting to create a file on a system that has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
- **-ENOENT** – when the file does not exist at the path;
- **-ENOTSUP** – when not implemented by underlying file system driver;
- **-EACCES** – when trying to truncate a file without opening it for write.

- `<0` – an other negative errno code, depending on a file system back-end.

int `fs_close`(struct *fs_file_t* *zfp)

Close file.

Flushes the associated stream and closes the file.

Parameters

- `zfp` – Pointer to the file object

Return values

- `0` – on success;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – a negative errno code on error.

int `fs_unlink`(const char *path)

Unlink file.

Deletes the specified file or directory

Parameters

- `path` – Path to the file or directory to delete

Return values

- `0` – on success;
- `-EINVAL` – when a bad file name is given;
- `-EROFS` – if file is read-only, or when file system has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – an other negative errno code on error.

int `fs_rename`(const char *from, const char *to)

Rename file or directory.

Performs a rename and / or move of the specified source path to the specified destination. The source path can refer to either a file or a directory. All intermediate directories in the destination path must already exist. If the source path refers to a file, the destination path must contain a full filename path, rather than just the new parent directory. If an object already exists at the specified destination path, this function causes it to be unlinked prior to the rename (i.e., the destination gets clobbered).

Note

Current implementation does not allow moving files between mount points.

Parameters

- `from` – The source path
- `to` – The destination path

Return values

- `0` – on success;
- `-EINVAL` – when a bad file name is given, or when rename would cause move between mount points;

- `-EROFS` – if file is read-only, or when file system has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – an other negative errno code on error.

ssize_t **fs_read**(struct *fs_file_t* *zfp, void *ptr, size_t size)

Read file.

Reads up to `size` bytes of data to `ptr` pointed buffer, returns number of bytes read. A returned value may be lower than `size` if there were fewer bytes available than requested.

Parameters

- `zfp` – Pointer to the file object
- `ptr` – Pointer to the data buffer
- `size` – Number of bytes to be read

Return values

- `>=0` – a number of bytes read, on success;
- `-EBADF` – when invoked on zfp that represents unopened/closed file;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – a negative errno code on error.

ssize_t **fs_write**(struct *fs_file_t* *zfp, const void *ptr, size_t size)

Write file.

Attempts to write `size` number of bytes to the specified file. If a negative value is returned from the function, the file pointer has not been advanced. If the function returns a non-negative number that is lower than `size`, the global `errno` variable should be checked for an error code, as the device may have no free space for data.

Parameters

- `zfp` – Pointer to the file object
- `ptr` – Pointer to the data buffer
- `size` – Number of bytes to be written

Return values

- `>=0` – a number of bytes written, on success;
- `-EBADF` – when invoked on zfp that represents unopened/closed file;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – an other negative errno code on error.

int **fs_seek**(struct *fs_file_t* *zfp, off_t offset, int whence)

Seek file.

Moves the file position to a new location in the file. The `offset` is added to file position based on the `whence` parameter.

Parameters

- `zfp` – Pointer to the file object
- `offset` – Relative location to move the file pointer to
- `whence` – Relative location from where offset is to be calculated.

- FS_SEEK_SET for the beginning of the file;
- FS_SEEK_CUR for the current position;
- FS_SEEK_END for the end of the file.

Return values

- `0` – on success;
- `-EBADF` – when invoked on zfp that represents unopened/closed file;
- `-ENOTSUP` – if not supported by underlying file system driver;
- `<0` – an other negative errno code on error.

off_t **fs_tell**(struct *fs_file_t* *zfp)

Get current file position.

Retrieves and returns the current position in the file stream.

The current revision does not validate the file object.

Parameters

- `zfp` – Pointer to the file object

Return values

- `>=` – 0 a current position in file;
- `-EBADF` – when invoked on zfp that represents unopened/closed file;
- `-ENOTSUP` – if not supported by underlying file system driver;
- `<0` – an other negative errno code on error.

int **fs_truncate**(struct *fs_file_t* *zfp, off_t length)

Truncate or extend an open file to a given size.

Truncates the file to the new length if it is shorter than the current size of the file. Expands the file if the new length is greater than the current size of the file. The expanded region would be filled with zeroes.

Note

In the case of expansion, if the volume got full during the expansion process, the function will expand to the maximum possible length and return success. Caller should check if the expanded size matches the requested length.

Parameters

- `zfp` – Pointer to the file object
- `length` – New size of the file in bytes

Return values

- `0` – on success;
- `-EBADF` – when invoked on zfp that represents unopened/closed file;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – an other negative errno code on error.

int `fs_sync`(struct *fs_file_t* *zfp)

Flush cached write data buffers of an open file.

The function flushes the cache of an open file; it can be invoked to ensure data gets written to the storage media immediately, e.g. to avoid data loss in case if power is removed unexpectedly.

> **Note**
>
> Closing a file will cause caches to be flushed correctly so the function need not be called when the file is being closed.

Parameters

- `zfp` – Pointer to the file object

Return values

- `0` – on success;
- `-EBADF` – when invoked on zfp that represents unopened/closed file;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – a negative errno code on error.

int `fs_mkdir`(const char *path)

Directory create.

Creates a new directory using specified path.

Parameters

- `path` – Path to the directory to create

Return values

- `0` – on success;
- `-EEXIST` – if entry of given name exists;
- `-EROFS` – if `path` is within read-only directory, or when file system has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – an other negative errno code on error

int `fs_opendir`(struct *fs_dir_t* *zdp, const char *path)

Directory open.

Opens an existing directory specified by the path.

Parameters

- `zdp` – Pointer to the directory object
- `path` – Path to the directory to open

Return values

- `0` – on success;
- `-EINVAL` – when a bad directory path is given;
- `-EBUSY` – when zdp is already used;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – a negative errno code on error.

int `fs_readdir`(struct *fs_dir_t* *zdp, struct *fs_dirent* *entry)

Directory read entry.

Reads directory entries of an open directory. In end-of-dir condition, the function will return 0 and set the `entry->name[0]` to 0.

> **Note**
>
> : Most existing underlying file systems do not generate POSIX special directory entries "." or "..". For consistency the abstraction layer will remove these from lower layer results so higher layers see consistent results.

Parameters

- `zdp` – Pointer to the directory object
- `entry` – Pointer to zfs_dirent structure to read the entry into

Return values

- `0` – on success or end-of-dir;
- `-ENOENT` – when no such directory found;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – a negative errno code on error.

int `fs_closedir`(struct *fs_dir_t* *zdp)

Directory close.

Closes an open directory.

Parameters

- `zdp` – Pointer to the directory object

Return values

- `0` – on success;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – a negative errno code on error.

int `fs_mount`(struct *fs_mount_t* *mp)

Mount filesystem.

Perform steps needed for mounting a file system like calling the file system specific mount function and adding the mount point to mounted file system list.

> **Note**
>
> Current implementation of ELM FAT driver allows only following mount points: "/RAM:","/NAND:","/CF:","/SD:","/SD2:","/USB:","/USB2:","/USB3:" or mount points that consist of single digit, e.g: "/0:", "/1:" and so forth.

Parameters

- `mp` – Pointer to the *fs_mount_t* structure. Referenced object is not changed if the mount operation failed. A reference is captured in the fs infrastructure if the mount operation succeeds, and the application must not mutate the structure contents until fs_unmount is successfully invoked on the same pointer.

Return values

- `0` – on success;
- `-ENOENT` – when file system type has not been registered;
- `-ENOTSUP` – when not supported by underlying file system driver; when `FS_MOUNT_FLAG_USE_DISK_ACCESS` is set but driver does not support it.
- `-EROFS` – if system requires formatting but `FS_MOUNT_FLAG_READ_ONLY` has been set;
- `<0` – an other negative errno code on error.

int `fs_unmount`(struct *fs_mount_t* *mp)

Unmount filesystem.

Perform steps needed to unmount a file system like calling the file system specific unmount function and removing the mount point from mounted file system list.

Parameters

- `mp` – Pointer to the *fs_mount_t* structure

Return values

- `0` – on success;
- `-EINVAL` – if no system has been mounted at given mount point;
- `-ENOTSUP` – when not supported by underlying file system driver;
- `<0` – an other negative errno code on error.

int `fs_readmount`(int *index, const char **name)

Get path of mount point at index.

This function iterates through the list of mount points and returns the directory name of the mount point at the given `index`. On success `index` is incremented and `name` is set to the mount directory name. If a mount point with the given `index` does not exist, `name` will be set to `NULL`.

Parameters

- `index` – Pointer to mount point index
- `name` – Pointer to pointer to path name

Return values

- `0` – on success;
- `-ENOENT` – if there is no mount point with given index.

int `fs_stat`(const char *path, struct *fs_dirent* *entry)

File or directory status.

Checks the status of a file or directory specified by the `path`.

> **Note**
>
> The file on a storage device may not be updated until it is closed.

Parameters

- `path` – Path to the file or directory
- `entry` – Pointer to the zfs_dirent structure to fill if the file or directory exists.

Return values

- `0` – on success;
- `-EINVAL` – when a bad directory or file name is given;
- `-ENOENT` – when no such directory or file is found;
- `-ENOTSUP` – when not supported by underlying file system driver;
- `<0` – negative errno code on error.

int `fs_statvfs`(const char *path, struct *fs_statvfs* *stat)

Retrieves statistics of the file system volume.

Returns the total and available space in the file system volume.

Parameters

- `path` – Path to the mounted directory
- `stat` – Pointer to the zfs_statvfs structure to receive the fs statistics.

Return values

- `0` – on success;
- `-EINVAL` – when a bad path to a directory, or a file, is given;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – an other negative errno code on error.

int `fs_mkfs`(int fs_type, uintptr_t dev_id, void *cfg, int flags)

Create fresh file system.

Parameters

- `fs_type` – Type of file system to create.
- `dev_id` – Id of storage device.
- `cfg` – Backend dependent init object. If NULL then default configuration is used.
- `flags` – Additional flags for file system implementation.

Return values

- `0` – on success;
- `<0` – negative errno code on error.

int `fs_register`(int type, const struct *fs_file_system_t* *fs)

Register a file system.

Register file system with virtual file system. Number of allowed file system types to be registered is controlled with the CONFIG_FILE_SYSTEM_MAX_TYPES Kconfig option.

Parameters

- `type` – Type of file system (ex: `FS_FATFS`)
- `fs` – Pointer to File system

Return values

- `0` – on success;
- `-EALREADY` – when a file system of a given type has already been registered;

- `-ENOSCP` – when there is no space left, in file system registry, to add this file system type.

int `fs_unregister`(int type, const struct *fs_file_system_t* *fs)

Unregister a file system.

Unregister file system from virtual file system.

Parameters

- `type` – Type of file system (ex: `FS_FATFS`)
- `fs` – Pointer to File system

Return values

- `0` – on success;
- `-EINVAL` – when file system of a given type has not been registered.

struct `fs_mount_t`

#include <fs.h> File system mount info structure.

Public Members

sys_dnode_t `node`

Entry for the fs_mount_list list.

int `type`

File system type.

const char *`mnt_point`

Mount point directory name (ex: “/fatfs”)

void *`fs_data`

Pointer to file system specific data.

void *`storage_dev`

Pointer to backend storage device.

size_t `mountp_len`

Length of Mount point string.

const struct *fs_file_system_t* *`fs`

Pointer to File system interface of the mount point.

uint8_t `flags`

Mount flags.

struct `fs_dirent`

#include <fs.h> Structure to receive file or directory information.

Used in functions that read the directory entries to get file or directory information.

Public Members

enum *fs_dir_entry_type* **type**
File/directory type (FS_DIR_ENTRY_FILE or FS_DIR_ENTRY_DIR)

char **name**[MAX_FILE_NAME + 1]
Name of file or directory.

size_t **size**
Size of file (0 if directory).

struct **fs_statvfs**
#include <fs.h> Structure to receive volume statistics.

Used to retrieve information about total and available space in the volume.

Public Members

unsigned long **f_bsize**
Optimal transfer block size.

unsigned long **f_frsize**
Allocation unit size.

unsigned long **f_blocks**
Size of FS in f_frsize units.

unsigned long **f_bfree**
Number of free blocks.

struct **fs_file_t**
#include <fs_interface.h> File object representing an open file.

The object needs to be initialized with *fs_file_t_init()*.

Public Members

void ***filep**
Pointer to file object structure.

const struct *fs_mount_t* ***mp**
Pointer to mount point structure.

fs_mode_t **flags**
Open/create flags.

struct **fs_dir_t**
#include <fs_interface.h> Directory object representing an open directory.

The object needs to be initialized with *fs_dir_t_init()*.

Public Members

void *dirp
: Pointer to directory object structure.

const struct *fs_mount_t* *mp
: Pointer to mount point structure.

struct fs_file_system_t
: *#include <fs_sys.h>* File System interface structure.

File operations

int (*open)(struct *fs_file_t* *filp, const char *fs_path, fs_mode_t flags)
: Opens or creates a file, depending on flags given.
  Param filp
  File to open/create.
  Param fs_path
  Path to the file.
  Param flags
  Flags for opening/creating the file.
  Return
  0 on success, negative errno code on fail.

ssize_t (*read)(struct *fs_file_t* *filp, void *dest, size_t nbytes)
: Reads nbytes number of bytes.
  Param filp
  File to read from.
  Param dest
  Destination buffer.
  Param nbytes
  Number of bytes to read.
  Return
  Number of bytes read on success, negative errno code on fail.

ssize_t (*write)(struct *fs_file_t* *filp, const void *src, size_t nbytes)
: Writes nbytes number of bytes.
  Param filp
  File to write to.
  Param src
  Source buffer.
  Param nbytes
  Number of bytes to write.
  Return
  Number of bytes written on success, negative errno code on fail.

int (*lseek)(struct *fs_file_t* *filp, off_t off, int whence)
: Moves the file position to a new location in the file.
  Param filp
  File to move.
  Param off
  Relative offset from the position specified by whence.

Param whence
Position in the file. Possible values: SEEK_CUR, SEEK_SET, SEEK_END.
Return
New position in the file or negative errno code on fail.

off_t (*`tell`)(struct *fs_file_t* *filp)

Retrieves the current position in the file.
Param filp
File to get the current position from.
Return
Current position in the file or negative errno code on fail.

int (*`truncate`)(struct *fs_file_t* *filp, off_t length)

Truncates/expands the file to the new length.
Param filp
File to truncate/expand.
Param length
New length of the file.
Return
0 on success, negative errno code on fail.

int (*`sync`)(struct *fs_file_t* *filp)

Flushes the cache of an open file.
Param filp
File to flush.
Return
0 on success, negative errno code on fail.

int (*`close`)(struct *fs_file_t* *filp)

Flushes the associated stream and closes the file.
Param filp
File to close.
Return
0 on success, negative errno code on fail.

Directory operations

int (*`opendir`)(struct *fs_dir_t* *dirp, const char *fs_path)

Opens an existing directory specified by the path.
Param dirp
Directory to open.
Param fs_path
Path to the directory.
Return
0 on success, negative errno code on fail.

int (*`readdir`)(struct *fs_dir_t* *dirp, struct *fs_dirent* *entry)

Reads directory entries of an open directory.
Param dirp
Directory to read from.
Param entry
Next directory entry in the dirp directory.
Return
0 on success, negative errno code on fail.

int (*`closedir`)(struct *fs_dir_t* *dirp)

Closes an open directory.

Param dirp
Directory to close.

Return
0 on success, negative errno code on fail.

File system level operations

int (*`mount`)(struct *fs_mount_t* *mountp)

Mounts a file system.

Param mountp
Mount point.

Return
0 on success, negative errno code on fail.

int (*`unmount`)(struct *fs_mount_t* *mountp)

Unmounts a file system.

Param mountp
Mount point.

Return
0 on success, negative errno code on fail.

int (*`unlink`)(struct *fs_mount_t* *mountp, const char *name)

Deletes the specified file or directory.

Param mountp
Mount point.

Param name
Path to the file or directory to delete.

Return
0 on success, negative errno code on fail.

int (*`rename`)(struct *fs_mount_t* *mountp, const char *from, const char *to)

Renames a file or directory.

Param mountp
Mount point.

Param from
Path to the file or directory to rename.

Param to
New name of the file or directory.

Return
0 on success, negative errno code on fail.

int (*`mkdir`)(struct *fs_mount_t* *mountp, const char *name)

Creates a new directory using specified path.

Param mountp
Mount point.

Param name
Path to the directory to create.

Return
0 on success, negative errno code on fail.

int (***stat**)(struct *fs_mount_t* *mountp, const char *path, struct *fs_dirent* *entry)

Checks the status of a file or directory specified by the path.

Param mountp
Mount point.
Param path
Path to the file or directory.
Param entry
Directory entry.
Return
0 on success, negative errno code on fail.

int (***statvfs**)(struct *fs_mount_t* *mountp, const char *path, struct *fs_statvfs* *stat)

Returns the total and available space on the file system volume.

Param mountp
Mount point.
Param path
Path to the file or directory.
Param stat
File system statistics.
Return
0 on success, negative errno code on fail.

int (***mkfs**)(uintptr_t dev_id, void *cfg, int flags)

Formats a device to specified file system type.

Available only if `CONFIG_FILE_SYSTEM_MKFS` is enabled.

Note

This operation destroys existing data on the target device.

Param dev_id
Device identifier.
Param cfg
File system configuration.
Param flags
Formatting flags.
Return
0 on success, negative errno code on fail.

4.8 Formatted Output

Applications as well as Zephyr itself requires infrastructure to format values for user consumption. The standard C99 library `*printf()` functionality fulfills this need for streaming output devices or memory buffers, but in an embedded system devices may not accept streamed data and memory may not be available to store the formatted output.

Internal Zephyr API traditionally provided this both for `printk()` and for Zephyr's internal minimal libc, but with separate internal interfaces. Logging, tracing, shell, and other applications made use of either these APIs or standard libc routines based on build options.

The *cbprintf()* public APIs convert C99 format strings and arguments, providing output produced one character at a time through a callback mechanism, replacing the original internal functions and providing support for almost all C99 format specifications. Existing use of

s*printf() C libraries in Zephyr can be converted to *snprintfcb()* to avoid pulling in libc implementations.

Several Kconfig options control the set of features that are enabled, allowing some control over features and memory usage:

- CONFIG_CBPRINTF_FULL_INTEGRAL or CONFIG_CBPRINTF_REDUCED_INTEGRAL
- CONFIG_CBPRINTF_FP_SUPPORT
- CONFIG_CBPRINTF_FP_A_SUPPORT
- CONFIG_CBPRINTF_FP_ALWAYS_A
- CONFIG_CBPRINTF_N_SPECIFIER

CONFIG_CBPRINTF_LIBC_SUBSTS can be used to provide functions that behave like standard libc functions but use the selected cbprintf formatter rather than pulling in another formatter from libc.

In addition CONFIG_CBPRINTF_NANO can be used to revert back to the very space-optimized but limited formatter used for printk() before this capability was added.

4.8.1 Cbprintf Packaging

Typically, strings are formatted synchronously when a function from printf family is called. However, there are cases when it is beneficial that formatting is deferred. In that case, a state (format string and arguments) must be captured. Such state forms a self-contained package which contains format string and arguments. Additionally, package may contain copies of strings which are part of a format string (format string or any %s argument). Package primary content resembles va_list stack frame thus standard formatting functions are used to process a package. Since package contains data which is processed as va_list frame, strict alignment must be maintained. Due to required padding, size of the package depends on alignment. When package is copied, it should be copied to a memory block with the same alignment as origin.

Package can have following variants:

- **Self-contained** - non read-only strings appended to the package. String can be formatted from such package as long as there is access to read-only string locations. Package may contain information where read-only strings are located within the package. That information can be used to convert packet to fully self-contained package.
- **Fully self-contained** - all strings are appended to the package. String can be formatted from such package without any external data.
- **Transient**- only arguments are stored. Package contain information where pointers to non read-only strings are located within the package. Optionally, it may contain read-only string location information. String can be formatted from such package as long as non read-only strings are still valid and read-only strings are accessible. Alternatively, package can be converted to **self-contained** package or **fully self-contained** if information about read-only string locations is present in the package.

Package can be created using two methods:

- runtime - using *cbprintf_package()* or *cbvprintf_package()*. This method scans format string and based on detected format specifiers builds the package.
- static - types of arguments are detected at compile time by the preprocessor and package is created as simple assignments to a provided memory. This method is significantly faster than runtime (more than 15 times) but has following limitations: requires _Generic keyword (C11 feature) to be supported by the compiler and cannot distinguish between %p and %s if char pointer is used. It treats all (unsigned) char pointers as %s thus it will attempt to append string to a package. It can be handled correctly during conversion from **transient** package to **self-contained** package using CBPRINTF_PACKAGE_CONVERT_PTR_CHECK

flag. However, it requires access to the format string and it is not always possible thus it is recommended to cast char pointers used for %p to `void *`. There is a logging warning generated by *cbprintf_package_convert()* called with CBPRINTF_PACKAGE_CONVERT_PTR_CHECK flag when char pointer is used with %p.

Several Kconfig options control behavior of the packaging:

- CONFIG_CBPRINTF_PACKAGE_LONGDOUBLE
- CONFIG_CBPRINTF_STATIC_PACKAGE_CHECK_ALIGNMENT

Cbprintf package conversion

It is possible to convert package to a variant which contains more information, e.g **transient** package can be converted to **self-contained**. Conversion to **fully self-contained** package is possible if CBPRINTF_PACKAGE_ADD_RO_STR_POS flag was used when package was created.

cbprintf_package_copy() is used to calculate space needed for the new package and to copy and convert a package.

Cbprintf package format

Format of the package contains paddings which are platform specific. Package consists of header which contains size of package (excluding appended strings) and number of appended strings. It is followed by the arguments which contains alignment paddings and resembles *va_list* stack frame. It is followed by data associated with character pointer arguments used by the string which are not appended to the string (but may be appended later by cbprinf_package_convert()). Finally, package, optionally, contains appended strings. Each string contains 1 byte header which contains index of the location where address argument is stored. During packaging address is set to null and before string formatting it is updated to point to the current string location within the package. Updating address argument must happen just before string formatting since address changes whenever package is copied.

Header sizeof(void *)	1 byte: Argument list size including header and *fmt* (in 32 bit words)
	1 byte: Number of strings appended to the package
	1 byte: Number of read-only string argument locations
	1 byte: Number of transient string argument locations
	platform specific padding to sizeof(void *)
Arguments	Pointer to *fmt* (or null if *fmt* is appended to the package)
	(optional padding for platform specific alignment)
	argument 0
	(optional padding for platform specific alignment)
	argument 1
	...
String location information (optional)	Indexes of words within the package where read-only strings are located
	Pairs of argument index and argument location index where transient strings are located
Appended strings (optional)	1 byte: Index within the package to the location of associated argument
	Null terminated string
	...

Warning

If CONFIG_MINIMAL_LIBC is selected in combination with CONFIG_CBPRINTF_NANO formatting with C standard library functions like printf or snprintf is limited. Among other things the %n specifier, most format flags, precision control, and floating point are not supported.

Limitations and recommendations

- C11 _Generic support is required by the compiler to use static (fast) packaging.
- It is recommended to cast any character pointer used with %p format specifier to other pointer type (e.g. void *). If format string is not accessible then only static packaging is possible and it will append all detected strings. Character pointer used for %p will be considered as string pointer. Copying from unexpected location can have serious consequences (e.g., memory fault or security violation).

4.8.2 API Reference

group cbprintf_apis

Defines

CBPRINTF_PACKAGE_ALIGNMENT

Required alignment of the buffer used for packaging.

CBPRINTF_MUST_RUNTIME_PACKAGE(flags, ...)

Determine if string must be packaged in run time.

Static packaging can be applied if size of the package can be determined at compile time. In general, package size can be determined at compile time if there are no string arguments which might be copied into package body if they are considered transient.

Note

By default any char pointers are considered to be pointing at transient strings. This can be narrowed down to non const pointers by using CBPRINTF_PACKAGE_CONST_CHAR_RO.

Parameters

- ... – String with arguments.
- flags – option flags. See Package flags.

Return values

- 1 – if string must be packaged in run time.
- 0 – string can be statically packaged.

CBPRINTF_STATIC_PACKAGE(packaged, inlen, outlen, align_offset, flags, ...)

Statically package string.

Build string package from formatted string. It assumes that formatted string is in the read only memory.

If _Generic is not supported then runtime packaging is performed.

Parameters

- **packaged** – pointer to where the packaged data can be stored. Pass a null pointer to skip packaging but still calculate the total space required. The data stored here is relocatable, that is it can be moved to another contiguous block of memory. It must be aligned to the size of the longest argument. It is recommended to use CBPRINTF_PACKAGE_ALIGNMENT for alignment.
- **inlen** – set to the number of bytes available at packaged. If packaged is NULL the value is ignored.
- **outlen** – variable updated to the number of bytes required to completely store the packed information. If input buffer was too small it is set to -ENOSPC.
- **align_offset** – input buffer alignment offset in bytes. Where offset 0 means that buffer is aligned to CBPRINTF_PACKAGE_ALIGNMENT. Xtensa requires that packaged is aligned to CBPRINTF_PACKAGE_ALIGNMENT so it must be multiply of CBPRINTF_PACKAGE_ALIGNMENT or 0.
- **flags** – option flags. See Package flags.
- **...** – formatted string with arguments. Format string must be constant.

Typedefs

typedef int (*cbprintf_cb)()

Signature for a cbprintf callback function.

This function expects two parameters:

- c a character to output. The output behavior should be as if this was cast to an unsigned char.
- ctx a pointer to an object that provides context for the output operation.

The declaration does not specify the parameter types. This allows a function like fputc to be used without requiring all context pointers to be to a FILE object.

Return

the value of c cast to an unsigned char then back to int, or a negative error code that will be returned from *cbprintf()*.

typedef int (*cbprintf_cb_local)(int c, void *ctx)

typedef int (*cbprintf_convert_cb)(const void *buf, size_t len, void *ctx)

Signature for a cbprintf multibyte callback function.

return Amount of copied data or negative error code.

Param buf
data.

Param len
data length.

Param ctx
a pointer to an object that provides context for the operation.

typedef int (*`cbvprintf_external_formatter_func`)(*cbprintf_cb* out, void *ctx, const char *fmt, va_list ap)

Signature for a external formatter function identical to cbvprintf.

This function expects the following parameters:

Param out
the function used to emit each generated character.

Param ctx
a pointer to an object that provides context for the external formatter.

Param fmt
a standard ISO C format string with characters and conversion specifications.

Param ap
captured stack arguments corresponding to the conversion specifications found within `fmt`.

Return
vprintf like return values: the number of characters printed, or a negative error value returned from external formatter.

Functions

int `cbprintf_package`(void *packaged, size_t len, uint32_t flags, const char *format, ...)

Capture state required to output formatted data later.

Like *cbprintf()* but instead of processing the arguments and emitting the formatted results immediately all arguments are captured so this can be done in a different context, e.g. when the output function can block.

In addition to the values extracted from arguments this will ensure that copies are made of the necessary portions of any string parameters that are not confirmed to be stored in read-only memory (hence assumed to be safe to refer to directly later).

Parameters

- `packaged` – pointer to where the packaged data can be stored. Pass a null pointer to store nothing but still calculate the total space required. The data stored here is relocatable, that is it can be moved to another contiguous block of memory. However, under condition that alignment is maintained. It must be aligned to at least the size of a pointer.
- `len` – this must be set to the number of bytes available at packaged if it is not null. If packaged is null then it indicates hypothetical buffer alignment offset in bytes compared to CBPRINTF_PACKAGE_ALIGNMENT alignment. Buffer alignment offset impacts returned size of the package. Xtensa requires that buffer is always aligned to CBPRINTF_PACKAGE_ALIGNMENT so it must be multiply of CBPRINTF_PACKAGE_ALIGNMENT or 0 when packaged is null.
- `flags` – option flags. See Package flags.

- **format** – a standard ISO C format string with characters and conversion specifications.
- **...** – arguments corresponding to the conversion specifications found within format.

Return values

- **nonegative** – the number of bytes successfully stored at packaged. This will not exceed len.
- **-EINVAL** – if format is not acceptable
- **-EFAULT** – if packaged alignment is not acceptable
- **-ENOSPC** – if packaged was not null and the space required to store exceed len.

int **cbvprintf_package**(void *packaged, size_t len, uint32_t flags, const char *format, va_list ap)

Capture state required to output formatted data later.

Like *cbprintf()* but instead of processing the arguments and emitting the formatted results immediately all arguments are captured so this can be done in a different context, e.g. when the output function can block.

In addition to the values extracted from arguments this will ensure that copies are made of the necessary portions of any string parameters that are not confirmed to be stored in read-only memory (hence assumed to be safe to refer to directly later).

Parameters

- **packaged** – pointer to where the packaged data can be stored. Pass a null pointer to store nothing but still calculate the total space required. The data stored here is relocatable, that is it can be moved to another contiguous block of memory. The pointer must be aligned to a multiple of the largest element in the argument list.
- **len** – this must be set to the number of bytes available at packaged. Ignored if packaged is NULL.
- **flags** – option flags. See Package flags.
- **format** – a standard ISO C format string with characters and conversion specifications.
- **ap** – captured stack arguments corresponding to the conversion specifications found within format.

Return values

- **nonegative** – the number of bytes successfully stored at packaged. This will not exceed len.
- **-EINVAL** – if format is not acceptable
- **-ENOSPC** – if packaged was not null and the space required to store exceed len.

int **cbprintf_package_convert**(void *in_packaged, size_t in_len, *cbprintf_convert_cb* cb, void *ctx, uint32_t flags, uint16_t *strl, size_t strl_len)

Convert a package.

Converting may include appending strings used in the package to the package body. If input package was created with CBPRINTF_PACKAGE_ADD_RO_STR_POS or CBPRINTF_PACKAGE_ADD_RW_STR_POS, it contains information where strings are located within the package. This information can be used to copy strings during the conversion.

cb is called with portions of the output package. At the end of the conversion cb is called with null buffer.

Parameters

- **in_packaged** – Input package.
- **in_len** – Input package length. If 0 package length will be retrieved from the in_packaged
- **cb** – callback called with portions of the converted package. If null only length of the output package is calculated.
- **ctx** – Context provided to the cb.
- **flags** – Flags. See Package convert flags.
- **strl** – **[inout]** if packaged is null, it is a pointer to the array where strl_len first string lengths will is stored. If packaged is not null, it contains lengths of first strl_len strings. It can be used to optimize copying so that string length is calculated only once (at length calculation phase when packaged is null.)
- **strl_len** – Number of elements in strl array.

Return values

- **Positive** – output package size.
- **-ENOSPC** – if packaged was not null and the space required to store exceed len.

static inline int **cbprintf_package_copy**(void *in_packaged, size_t in_len, void *packaged, size_t len, uint32_t flags, uint16_t *strl, size_t strl_len)

Copy package with optional appending of strings.

cbprintf_package_convert is used to convert and store converted package in the new location.

Parameters

- **in_packaged** – Input package.
- **in_len** – Input package length. If 0 package length will be retrieved from the in_packaged
- **packaged** – **[out]** Output package. If null only length of the output package is calculated.
- **len** – Available space in the location pointed by packaged. Not used when packaged is null.
- **flags** – Flags. See Package convert flags.
- **strl** – **[inout]** if packaged is null, it is a pointer to the array where strl_len first string lengths will is stored. If packaged is not null, it contains lengths of first strl_len strings. It can be used to optimize copying so that string length is calculated only once (at length calculation phase when packaged is null.)
- **strl_len** – Number of elements in strl array.

Return values

- **Positive** – Output package size.
- **-ENOSPC** – if packaged was not null and the space required to store exceed len.

static inline int **cbprintf_fsc_package**(void *in_packaged, size_t in_len, void *packaged, size_t len)

Convert package to fully self-contained (fsc) package.

Package may not be self contain since strings by default are stored by address. Package may be partially self-contained when transient (not read only) strings are appended to the package. Such package can be decoded only when there is an access to read-only strings.

Fully self-contained has (fsc) contains all strings used in the package. A package can be converted to fsc package if it was create with CBPRINTF_PACKAGE_ADD_RO_STR_POS flag. Such package will contain necessary data to find read only strings in the package and copy them into the package body.

Parameters

- **in_packaged** – pointer to original package created with CBPRINTF_PACKAGE_ADD_RO_STR_POS.
- **in_len** – `in_packaged` length.
- **packaged** – pointer to location where fully self-contained version of the input package will be written. Pass a null pointer to calculate space required.
- **len** – must be set to the number of bytes available at `packaged`. Not used if `packaged` is null.

Return values

- **nonegative** – the number of bytes successfully stored at `packaged`. This will not exceed `len`. If `packaged` is null, calculated length.
- **-ENOSPC** – if `packaged` was not null and the space required to store exceed `len`.
- **-EINVAL** – if `in_packaged` is null.

int **cbpprintf_external**(*cbprintf_cb* out, *cbvprintf_external_formatter_func* formatter, void *ctx, void *packaged)

Generate the output for a previously captured format operation using an external formatter.

> **Note**
>
> Memory indicated by `packaged` will be modified in a non-destructive way, meaning that it could still be reused with this function again.

Parameters

- **out** – the function used to emit each generated character.
- **formatter** – external formatter function.
- **ctx** – a pointer to an object that provides context for the external formatter.
- **packaged** – the data required to generate the formatted output, as captured by *cbprintf_package()* or *cbvprintf_package()*. The alignment requirement on this data is the same as when it was initially created.

Returns

printf like return values: the number of characters printed, or a negative error value returned from external formatter.

int **cbprintf**(*cbprintf_cb* out, void *ctx, const char *format, ...)

*printf-like output through a callback.

This is essentially printf() except the output is generated character-by-character using the provided `out` function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.

All formatting specifiers of C99 are recognized, and most are supported if the functionality is enabled.

> **Note**
>
> The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

Parameters

- **out** – the function used to emit each generated character.
- **ctx** – context provided when invoking out
- **format** – a standard ISO C format string with characters and conversion specifications.
- `...` – arguments corresponding to the conversion specifications found within `format`.

Returns

the number of characters printed, or a negative error value returned from invoking `out`.

static inline int **cbvprintf**(*cbprintf_cb* out, void *ctx, const char *format, va_list ap)

varargs-aware *printf-like output through a callback.

This is essentially vsprintf() except the output is generated character-by-character using the provided `out` function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.

> **Note**
>
> This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

> **Note**
>
> The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

Parameters

- **out** – the function used to emit each generated character.
- **ctx** – context provided when invoking out
- **format** – a standard ISO C format string with characters and conversion specifications.
- **ap** – a reference to the values to be converted.

Returns
the number of characters generated, or a negative error value returned from invoking `out`.

static inline int **cbvprintf_tagged_args**(*cbprintf_cb* out, void *ctx, const char *format, va_list ap)

varargs-aware *printf-like output through a callback with tagged arguments.

This is essentially vsprintf() except the output is generated character-by-character using the provided `out` function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.

Note that the argument list `ap` are tagged.

Note

This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

Note

The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

Parameters

- **out** – the function used to emit each generated character.
- **ctx** – context provided when invoking out
- **format** – a standard ISO C format string with characters and conversion specifications.
- **ap** – a reference to the values to be converted.

Returns
the number of characters generated, or a negative error value returned from invoking `out`.

static inline int **cbpprintf**(*cbprintf_cb* out, void *ctx, void *packaged)

Generate the output for a previously captured format operation.

Note

Memory indicated by `packaged` will be modified in a non-destructive way, meaning that it could still be reused with this function again.

Parameters

- **out** – the function used to emit each generated character.
- **ctx** – context provided when invoking out
- **packaged** – the data required to generate the formatted output, as captured by *cbprintf_package()* or *cbvprintf_package()*. The alignment requirement on this data is the same as when it was initially created.

Returns
the number of characters printed, or a negative error value returned from invoking `out`.

int **fprintfcb**(FILE *stream, const char *format, ...)
fprintf using Zephyrs cbprintf infrastructure.

return The number of characters printed.

> **Note**
>
> This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

> **Note**
>
> The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

Parameters

- **stream** – the stream to which the output should be written.
- **format** – a standard ISO C format string with characters and conversion specifications.
- ... – arguments corresponding to the conversion specifications found within format.

int **vfprintfcb**(FILE *stream, const char *format, va_list ap)
vfprintf using Zephyrs cbprintf infrastructure.

> **Note**
>
> This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

> **Note**
>
> The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

Parameters

- **stream** – the stream to which the output should be written.
- **format** – a standard ISO C format string with characters and conversion specifications.
- **ap** – a reference to the values to be converted.

Returns
The number of characters printed.

int **printfcb**(const char *format, ...)
printf using Zephyrs cbprintf infrastructure.

> **Note**
>
> This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

Note

The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

Parameters

- **format** – a standard ISO C format string with characters and conversion specifications.
- **...** – arguments corresponding to the conversion specifications found within format.

Returns
The number of characters printed.

int **vprintfcb**(const char *format, va_list ap)

vprintf using Zephyrs cbprintf infrastructure.

Note

This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

Note

The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

Parameters

- **format** – a standard ISO C format string with characters and conversion specifications.
- **ap** – a reference to the values to be converted.

Returns
The number of characters printed.

int **snprintfcb**(char *str, size_t size, const char *format, ...)

snprintf using Zephyrs cbprintf infrastructure.

Note

This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

Note

The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

Parameters

- **str** – where the formatted content should be written

- **size** – maximum number of chaacters for the formatted output, including the terminating null byte.
- **format** – a standard ISO C format string with characters and conversion specifications.
- ... – arguments corresponding to the conversion specifications found within format.

Returns
The number of characters that would have been written to str, excluding the terminating null byte. This is greater than the number actually written if size is too small.

int **vsnprintfcb**(char *str, size_t size, const char *format, va_list ap)
vsnprintf using Zephyrs cbprintf infrastructure.

> **Note**
> This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

> **Note**
> The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

Parameters

- **str** – where the formatted content should be written
- **size** – maximum number of chaacters for the formatted output, including the terminating null byte.
- **format** – a standard ISO C format string with characters and conversion specifications.
- **ap** – a reference to the values to be converted.

Returns
The number of characters that would have been written to str, excluding the terminating null byte. This is greater than the number actually written if size is too small.

4.9 Input

The input subsystem provides an API for dispatching input events from input devices to the application.

4.9.1 Input Events

The subsystem is built around the *input_event* structure. An input event represents a change in an individual event entity, for example the state of a single button, or a movement in a single axis.

The *input_event* structure describes the specific event, and includes a synchronization bit to indicate that the device reached a stable state, for example when the events corresponding to multiple axes of a multi-axis device have been reported.

4.9.2 Input Devices

An input device can report input events directly using *input_report()* or any related function; for example buttons or other on-off input entities would use *input_report_key()*.

Complex devices may use a combination of multiple events, and set the sync bit once the output is stable.

The input_report* functions take a *device* pointer, which is used to indicate which device reported the event and can be used by subscribers to only receive events from a specific device. If there's no actual device associated with the event, it can be set to NULL, in which case only subscribers with no device filter will receive the event.

4.9.3 Application API

An application can register a callback using the *INPUT_CALLBACK_DEFINE* macro. If a device node is specified, the callback is only invoked for events from the specific device, otherwise the callback will receive all the events in the system. This is the only type of filtering supported, any more complex filtering logic has to be implemented in the callback itself.

The subsystem can operate synchronously or by using an event queue, depending on the CONFIG_INPUT_MODE option. If the input thread is used, all the events are added to a queue and executed in a common input thread. If the thread is not used, the callback are invoked directly in the input driver context.

The synchronous mode can be used in a simple application to keep a minimal footprint, or in a complex application with an existing event model, where the callback is just a wrapper to pipe back the event in a more complex application specific event system.

4.9.4 HID code mapping

A common use case for input devices is to use them to generate HID reports. For this purpose, the *input_to_hid_code()* and *input_to_hid_modifier()* functions can be used to map input codes to HID codes and modifiers.

4.9.5 Kscan Compatibility

Input devices generating X/Y/Touch events can be used in existing applications based on the *Keyboard Scan* API by enabling both CONFIG_INPUT and CONFIG_KSCAN, defining a zephyr,kscan-input node as a child node of the corresponding input device and pointing the zephyr,keyboard-scan chosen node to the compatibility device node, for example:

```
chosen {
    zephyr,keyboard-scan = &kscan_input;
};

ft5336@38 {
    ...
    kscan_input: kscan-input {
        compatible = "zephyr,kscan-input";
    };
};
```

4.9.6 General Purpose Drivers

- adc-keys: for buttons connected to a resistor ladder.

- `analog-axis`: for absolute position devices connected to an ADC input (thumbsticks, sliders...).
- `gpio-kbd-matrix`: for GPIO-connected keyboard matrices.
- `gpio-keys`: for switches directly connected to a GPIO, implements button debouncing.
- `gpio-qdec`: for GPIO-connected quadrature encoders.
- `input-keymap`: maps row/col/touch events from a keyboard matrix to key events.
- `zephyr,input-longpress`: listens for key events, emits events for short and long press.
- `zephyr,lvgl-button-input` `zephyr,lvgl-encoder-input` `zephyr,lvgl-keypad-input` `zephyr,lvgl-pointer-input`: listens for input events and translates those to various types of LVGL input devices.

4.9.7 Detailed Driver Documentation

GPIO Keyboard Matrix

The `gpio-kbd-matrix` driver supports a large variety of keyboard matrix hardware configurations and has numerous options to change its behavior. This is an overview of some common setups and how they can be supported by the driver.

The conventional configuration for all of these is that the driver reads on the row GPIOs (inputs) and selects on the columns GPIOs (output).

Base use case, no isolation diodes, interrupt capable GPIOs This is the common configuration found on consumer keyboards with membrane switches and flexible circuit boards, no isolation diodes, requires ghosting detection (which is enabled by default).

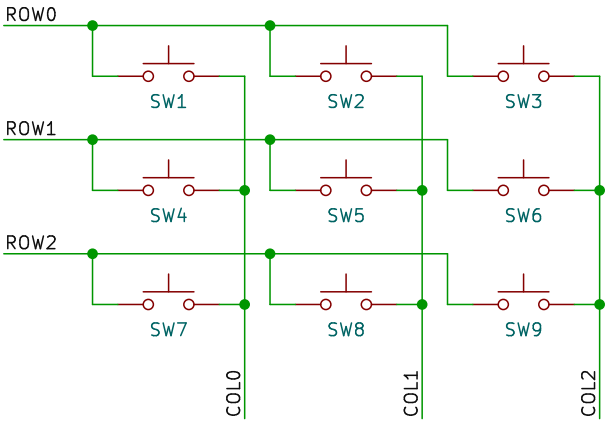

Fig. 1: A 3x3 matrix, no diodes

The system must support GPIO interrupts, and the interrupt can be enabled on all row GPIOs at the same time.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     row-gpios = <&gpio0 0 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 1 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 2 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>;
     col-gpios = <&gpio0 3 GPIO_ACTIVE_LOW>,
                 <&gpio0 4 GPIO_ACTIVE_LOW>,
                 <&gpio0 5 GPIO_ACTIVE_LOW>;
};
```

In this configuration the matrix scanning library enters idle mode once all keys are released, and the keyboard matrix thread only wakes up when a key has been pressed.

GPIOs for columns that are not currently selected are configured in high impedance mode. This means that the row state may need some time to settle to avoid misreading the key state from a column to the following one. The settle time can be tweaked by changing the `settle-time-us` property.

Isolation diodes If the matrix has isolation diodes for every key, then it's possible to:

- disable ghosting detection, allowing any key combination to be detected
- configuring the driver to drive unselected columns GPIO to inactive state rather than high impedance, this allows to reduce the settle time (potentially down to 0), and use the more efficient port wide GPIO read APIs (happens automatically if the GPIO pins are sequential)

Matrixes with diodes going from rows to columns must use pull-ups on rows and active low columns.

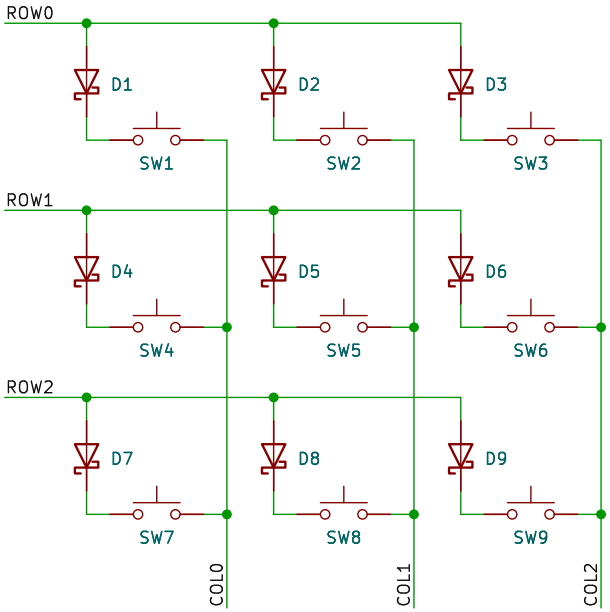

Fig. 2: A 3x3 matrix with row to column isolation diodes.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     row-gpios = <&gpio0 0 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 1 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 2 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>;
     col-gpios = <&gpio0 3 GPIO_ACTIVE_LOW>,
                 <&gpio0 4 GPIO_ACTIVE_LOW>,
                 <&gpio0 5 GPIO_ACTIVE_LOW>;
     col-drive-inactive;
     settle-time-us = <0>;
     no-ghostkey-check;
};
```

Matrixes with diodes going from columns to rows must use pull-downs on rows and active high columns.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     row-gpios = <&gpio0 0 (GPIO_PULL_DOWN | GPIO_ACTIVE_HIGH)>,
```

(continues on next page)

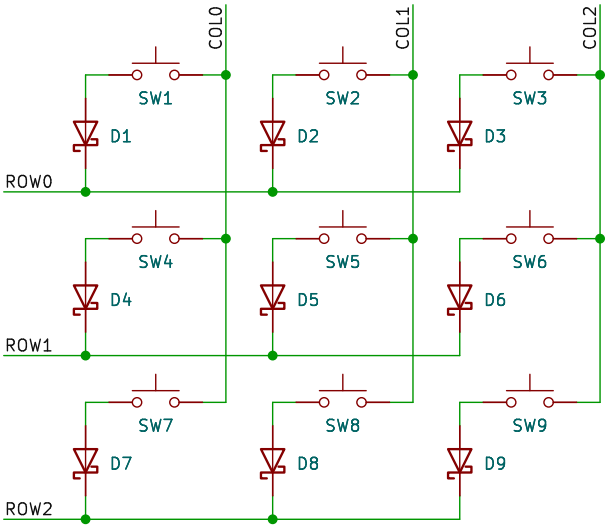

Fig. 3: A 3x3 matrix with column to row isolation diodes.

(continued from previous page)

```
                <&gpio0 1 (GPIO_PULL_DOWN | GPIO_ACTIVE_HIGH)>,
                <&gpio0 2 (GPIO_PULL_DOWN | GPIO_ACTIVE_HIGH)>;
    col-gpios = <&gpio0 3 GPIO_ACTIVE_HIGH>,
                <&gpio0 4 GPIO_ACTIVE_HIGH>,
                <&gpio0 5 GPIO_ACTIVE_HIGH>;
    col-drive-inactive;
    settle-time-us = <0>;
    no-ghostkey-check;
};
```

GPIO with no interrupt support Some GPIO controllers have limitations on GPIO interrupts, and may not support enabling interrupts on all row GPIOs at the same time.

In this case, the driver can be configured to not use interrupt at all, and instead idle by selecting all columns and keep polling on the row GPIOs, which is a single GPIO API operation if the pins are sequential.

This configuration can be enabled by setting the `idle-mode` property to `poll`:

```
kbd-matrix {
    compatible = "gpio-kbd-matrix";
    ...
    idle-mode = "poll";
};
```

GPIO multiplexer In more extreme cases, such as if the columns are using a multiplexer and it's impossible to select all of them at the same time, the driver can be configured to scan continuously.

This can be done by setting `idle-mode` to `scan` and `poll-timeout-ms` to `0`.

```
kbd-matrix {
    compatible = "gpio-kbd-matrix";
    ...
    poll-timeout-ms = <0>;
    idle-mode = "scan";
};
```

Row and column GPIO selection If the row GPIOs are sequential and on the same gpio controller, the driver automatically switches API to read from the whole GPIO port rather than the individual pins. This is particularly useful if the GPIOs are not memory mapped, for example on an I2C or SPI port expander, as this significantly reduces the number of transactions on the corresponding bus.

The same is true for column GPIOs, but only if the matrix is configured for `col-drive-inactive`, so that is only usable for matrixes with isolation diodes.

16-bit row support The driver uses an 8-bit datatype to store the row state by default, which limits the matrix row size to 8. This can be increased to 16 by enabling the `CONFIG_INPUT_KBD_MATRIX_16_BIT_ROW` option.

Actual key mask configuration If the key matrix is not complete, a map of the keys that are actually populated can be specified using the *actual-key-mask* property. This allows the matrix state to be filtered to remove keys that are not present before ghosting detection, potentially allowing key combinations that would otherwise be blocked by it.

For example for a 3x3 matrix missing a key:

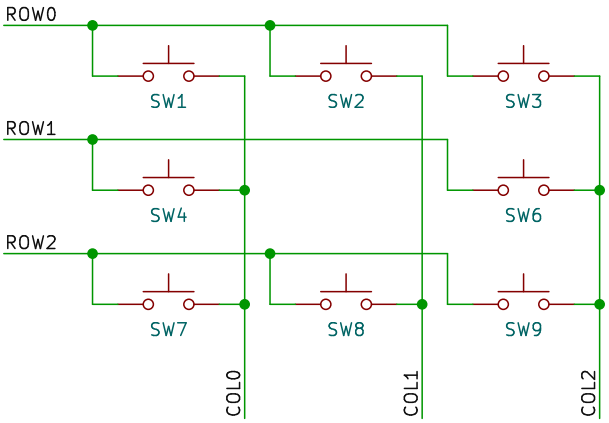

Fig. 4: A 3x3 matrix missing a key.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     ...
     actual-key-mask = <0x07 0x05 0x07>;
};
```

This would allow, for example, to detect pressing `Sw1`, `SW2` and `SW4` at the same time without triggering anti ghosting.

The actual key mask can be changed at runtime by enabling `CONFIG_INPUT_KBD_ACTUAL_KEY_MASK_DYNAMIC` and the using the *input_kbd_matrix_actual_key_mask_set()* API.

Keymap configuration Keyboard matrix devices report a series of x/y/touch events. These can be mapped to normal key events using the `input-keymap` driver.

For example, the following would setup a `keymap` device that take the x/y/touch events as an input and generate corresponding key events as an output:

```
kbd {
    ...
    keymap {
        compatible = "input-keymap";
        keymap = <
            MATRIX_KEY(0, 0, INPUT_KEY_1)
            MATRIX_KEY(0, 1, INPUT_KEY_2)
            MATRIX_KEY(0, 2, INPUT_KEY_3)
            MATRIX_KEY(1, 0, INPUT_KEY_4)
            MATRIX_KEY(1, 1, INPUT_KEY_5)
            MATRIX_KEY(1, 2, INPUT_KEY_6)
            MATRIX_KEY(2, 0, INPUT_KEY_7)
            MATRIX_KEY(2, 1, INPUT_KEY_8)
            MATRIX_KEY(2, 2, INPUT_KEY_9)
        >;
        row-size = <3>;
        col-size = <3>;
    };
};
```

Keyboard matrix shell commands The shell command `kbd_matrix_state_dump` can be used to test the functionality of any keyboard matrix driver implemented using the keyboard matrix library. Once enabled it logs the state of the matrix every time it changes, and once disabled it prints an or-mask of any key that has been detected, which can be used to set the `actual-key-mask` property.

The command can be enabled using the `CONFIG_INPUT_SHELL_KBD_MATRIX_STATE`.

Example usage:

```
uart:~$ device list
devices:
- kbd-matrix (READY)
uart:~$ input kbd_matrix_state_dump kbd-matrix
Keyboard state logging enabled for kbd-matrix
[00:01:41.678,466] <inf> input: kbd-matrix state [01 -- -- --] (1)
[00:01:41.784,912] <inf> input: kbd-matrix state [-- -- -- --] (0)
...
press more buttons
...
uart:~$ input kbd_matrix_state_dump off
Keyboard state logging disabled
[00:01:47.967,651] <inf> input: kbd-matrix key-mask [07 05 07 --] (8)
```

Keyboard matrix library The GPIO keyboard matrix driver is based on a generic keyboard matrix library, which implements the core functionalities such as scanning delays, debouncing, idle mode etc. This can be reused to implement other keyboard matrix drivers, potentially application specific.

group `input_kbd_matrix`

Keyboard Matrix API.

Defines

`INPUT_KBD_MATRIX_COLUMN_DRIVE_NONE`

Special drive_column argument for not driving any column.

INPUT_KBD_MATRIX_COLUMN_DRIVE_ALL
: Special drive_column argument for driving all the columns.

INPUT_KBD_MATRIX_SCAN_OCURRENCES
: Number of tracked scan cycles.

PRIkbdrow

INPUT_KBD_ACTUAL_KEY_MASK_CONST

INPUT_KBD_MATRIX_ROW_BITS
: Maximum number of rows.

INPUT_KBD_MATRIX_DATA_NAME(node_id, name)

INPUT_KBD_MATRIX_DT_DEFINE_ROW_COL(node_id, _row_size, _col_size)
: Defines the common keyboard matrix support data from devicetree, specify row and col count.

INPUT_KBD_MATRIX_DT_DEFINE(node_id)
: Defines the common keyboard matrix support data from devicetree.

INPUT_KBD_MATRIX_DT_INST_DEFINE_ROW_COL(inst, row_size, col_size)
: Defines the common keyboard matrix support data from devicetree instance, specify row and col count.

  Parameters

  - **inst** – Instance.
  - **row_size** – The matrix row count.
  - **col_size** – The matrix column count.

INPUT_KBD_MATRIX_DT_INST_DEFINE(inst)
: Defines the common keyboard matrix support data from devicetree instance.

  Parameters

  - **inst** – Instance.

INPUT_KBD_MATRIX_DT_COMMON_CONFIG_INIT_ROW_COL(node_id, _api, _row_size, _col_size)
: Initialize common keyboard matrix config from devicetree, specify row and col count.

  Parameters

  - **node_id** – The devicetree node identifier.
  - **_api** – Pointer to a *input_kbd_matrix_api* structure.
  - **_row_size** – The matrix row count.
  - **_col_size** – The matrix column count.

INPUT_KBD_MATRIX_DT_COMMON_CONFIG_INIT(node_id, api)
: Initialize common keyboard matrix config from devicetree.

  Parameters

  - **node_id** – The devicetree node identifier.
  - **api** – Pointer to a *input_kbd_matrix_api* structure.

INPUT_KBD_MATRIX_DT_INST_COMMON_CONFIG_INIT_ROW_COL(inst, api, row_size, col_size)

Initialize common keyboard matrix config from devicetree instance, specify row and col count.

Parameters

- **inst** – Instance.
- **api** – Pointer to a *input_kbd_matrix_api* structure.
- **row_size** – The matrix row count.
- **col_size** – The matrix column count.

INPUT_KBD_MATRIX_DT_INST_COMMON_CONFIG_INIT(inst, api)

Initialize common keyboard matrix config from devicetree instance.

Parameters

- **inst** – Instance.
- **api** – Pointer to a *input_kbd_matrix_api* structure.

INPUT_KBD_STRUCT_CHECK(config, data)

Validate the offset of the common data structures.

Parameters

- **config** – Name of the config structure.
- **data** – Name of the data structure.

Typedefs

typedef uint8_t **kbd_row_t**

Row entry data type.

Functions

int **input_kbd_matrix_actual_key_mask_set**(const struct *device* *dev, uint8_t row, uint8_t col, bool enabled)

Enables or disables a specific row, column combination in the actual key mask.

This allows enabling or disabling specific row, column combination in the actual key mask in runtime. It can be useful if some of the keys are not present in some configuration, and the specific configuration is determined in runtime. Requires CONFIG_INPUT_KBD_ACTUAL_KEY_MASK_DYNAMIC to be enabled.

Parameters

- **dev** – Pointer to the keyboard matrix device.
- **row** – The matrix row to enable or disable.
- **col** – The matrix column to enable or disable.
- **enabled** – Whether the specified row, col has to be enabled or disabled.

Return values

- **0** – If the change is successful.
- **-errno** – Negative errno if row or col are out of range for the device.

void **input_kbd_matrix_poll_start**(const struct *device* *dev)

Start scanning the keyboard matrix.

Starts the keyboard matrix scanning cycle, this should be called in reaction of a press event, after the device has been put in detect mode.

Parameters

- **dev** – Keyboard matrix device instance.

void **input_kbd_matrix_drive_column_hook**(const struct *device* *dev, int col)

Drive column hook.

This can be implemented by the application to handle column selection quirks. Called after the driver specific drive_column function. Requires CONFIG_INPUT_KBD_DRIVE_COLUMN_HOOK to be enabled.

Parameters

- **dev** – Keyboard matrix device instance.
- **col** – The column to drive, or *INPUT_KBD_MATRIX_COLUMN_DRIVE_NONE* or *INPUT_KBD_MATRIX_COLUMN_DRIVE_ALL*.

int **input_kbd_matrix_common_init**(const struct *device* *dev)

Common function to initialize a keyboard matrix device at init time.

This function must be called at the end of the device init function.

Parameters

- **dev** – Keyboard matrix device instance.

Return values

- **0** – If initialized successfully.
- **-errno** – Negative errno in case of failure.

struct **input_kbd_matrix_api**

#include <*input_kbd_matrix.h*> Keyboard matrix internal APIs.

Public Members

void (***drive_column**)(const struct *device* *dev, int col)

Request to drive a specific column.

Request to drive a specific matrix column, or none, or all.

Param dev
Pointer to the keyboard matrix device.

Param col
The column to drive, or *INPUT_KBD_MATRIX_COLUMN_DRIVE_NONE* or *INPUT_KBD_MATRIX_COLUMN_DRIVE_ALL*.

kbd_row_t (***read_row**)(const struct *device* *dev)

Read the matrix row.

Param dev
Pointer to the keyboard matrix device.

void (*set_detect_mode)(const struct *device* *dev, bool enabled)

Request to put the matrix in detection mode.

Request to put the driver in detection mode, this is called after a request to drive all the column and typically involves reenabling interrupts row pin changes.

Param dev
Pointer to the keyboard matrix device.

Param enable
Whether detection mode has to be enabled or disabled.

struct input_kbd_matrix_common_config

#include <*input_kbd_matrix.h*> Common keyboard matrix config.

This structure **must** be placed first in the driver's config structure.

struct input_kbd_matrix_common_data

#include <*input_kbd_matrix.h*> Common keyboard matrix data.

This structure **must** be placed first in the driver's data structure.

group input_interface

Input Interface.

Since
3.4

Version
0.1.0

Defines

INPUT_CALLBACK_DEFINE_NAMED(_dev, _callback, _user_data, name)

Register a callback structure for input events with a custom name.

Same as *INPUT_CALLBACK_DEFINE* but allows specifying a custom name for the callback structure. Useful if multiple callbacks are used for the same callback function.

INPUT_CALLBACK_DEFINE(_dev, _callback, _user_data)

Register a callback structure for input events.

The _dev field can be used to only invoke callback for events generated by a specific device. Setting dev to NULL causes callback to be invoked for every event.

Parameters

- **_dev** – *device* pointer or NULL.
- **_callback** – The callback function.
- **_user_data** – Pointer to user specified data.

Functions

int **input_report**(const struct *device* *dev, uint8_t type, uint16_t code, int32_t value, bool sync, *k_timeout_t* timeout)

Report a new input event.

This causes all the callbacks for the specified device to be executed, either synchronously or through the input thread if utilized.

Parameters

- **dev** – Device generating the event or NULL.
- **type** – Event type (see *INPUT_EV_CODES*).
- **code** – Event code (see *INPUT_KEY_CODES*, *INPUT_BTN_CODES*, *INPUT_ABS_CODES*, *INPUT_REL_CODES*, *INPUT_MSC_CODES*).
- **value** – Event value.
- **sync** – Set the synchronization bit for the event.
- **timeout** – Timeout for reporting the event, ignored if CONFIG_INPUT_MODE_SYNCHRONOUS is used.

Return values

- **0** – if the message has been processed.
- **negative** – if CONFIG_INPUT_MODE_THREAD is enabled and the message failed to be enqueued.

static inline int **input_report_key**(const struct *device* *dev, uint16_t code, int32_t value, bool sync, *k_timeout_t* timeout)

Report a new *INPUT_EV_KEY* input event, note that value is converted to either 0 or 1.

See also

input_report() for more details.

static inline int **input_report_rel**(const struct *device* *dev, uint16_t code, int32_t value, bool sync, *k_timeout_t* timeout)

Report a new *INPUT_EV_REL* input event.

See also

input_report() for more details.

static inline int **input_report_abs**(const struct *device* *dev, uint16_t code, int32_t value, bool sync, *k_timeout_t* timeout)

Report a new *INPUT_EV_ABS* input event.

> **See also**
>
> *input_report()* for more details.

bool **input_queue_empty**(void)

Returns true if the input queue is empty.

This can be used to batch input event processing until the whole queue has been emptied. Always returns true if `CONFIG_INPUT_MODE_SYNCHRONOUS` is enabled.

int16_t **input_to_hid_code**(uint16_t input_code)

Convert an input code to HID code.

Takes an input code as input and returns the corresponding HID code as output. The return value is -1 if the code is not found, if found it can safely be casted to a uint8_t type.

Parameters

- **input_code** – Event code (see *INPUT_KEY_CODES*).

Return values

- **the** – HID code corresponding to the input code.
- **-1** – if there's no HID code for the specified input code.

uint8_t **input_to_hid_modifier**(uint16_t input_code)

Convert an input code to HID modifier.

Takes an input code as input and returns the corresponding HID modifier as output or 0.

Parameters

- **input_code** – Event code (see *INPUT_KEY_CODES*).

Return values

- **the** – HID modifier corresponding to the input code.
- **0** – if there's no HID modifier for the specified input code.

struct **input_event**

#include <input.h> Input event structure.

This structure represents a single input event, for example a key or button press for a single button, or an absolute or relative coordinate for a single axis.

Public Members

const struct *device* ***dev**

Device generating the event or NULL.

uint8_t **sync**
Sync flag.

uint8_t **type**
Event type (see *INPUT_EV_CODES*).

uint16_t **code**
Event code (see *INPUT_KEY_CODES*, *INPUT_BTN_CODES*, *INPUT_ABS_CODES*, *INPUT_REL_CODES*, *INPUT_MSC_CODES*).

int32_t **value**
Event value.

struct **input_callback**
#include <*input.h*> Input callback structure.

Public Members

const struct *device* ***dev**
device pointer or NULL.

void (***callback**)(struct *input_event* *evt, void *user_data)
The callback function.

void ***user_data**
User data pointer.

4.9.10 Analog Axis API Reference

group input_analog_axis
: Analog axis API.

Typedefs

typedef void (*analog_axis_raw_data_t)(const struct *device* *dev, int channel, int16_t raw_val)
: Analog axis raw data callback.

Param dev
: Analog axis device.

Param channel
: Channel number.

Param raw_val
: Raw value for the channel.

Functions

void **analog_axis_set_raw_data_cb**(const struct *device* *dev, *analog_axis_raw_data_t* cb)

Set a raw data callback.

Set a callback to receive raw data for the specified analog axis device. This is meant to be use in the application to acquire the data to use for calibration. Set cb to NULL to disable the callback.

Parameters

- **dev** – Analog axis device.
- **cb** – An analog_axis_raw_data_t callback to use, NULL disable.

int **analog_axis_num_axes**(const struct *device* *dev)

Get the number of defined axes.

Return values

n – The number of defined axes for dev.

int **analog_axis_calibration_get**(const struct *device* *dev, int channel, struct *analog_axis_calibration* *cal)

Get the axis calibration data.

Parameters

- **dev** – Analog axis device.
- **channel** – Channel number.
- **cal** – Pointer to an *analog_axis_calibration* structure that is going to get set with the current calibration data.

Return values

- **0** – If successful.
- **-EINVAL** – If the specified channel is not valid.

int **analog_axis_calibration_set**(const struct *device* *dev, int channel, struct *analog_axis_calibration* *cal)

Set the axis calibration data.

Parameters

- **dev** – Analog axis device.
- **channel** – Channel number.
- **cal** – Pointer to an *analog_axis_calibration* structure with the new calibration data

Return values

- **0** – If successful.
- **-EINVAL** – If the specified channel is not valid.

int **analog_axis_calibration_save**(const struct *device* *dev)

Save the calibration data.

Save the calibration data permanently on the specified device, requires the *Settings* subsystem to be configured and initialized.

Parameters

- **dev** – Analog axis device.

Return values

- `0` – If successful.
- `-errno` – In case of any other error.

struct `analog_axis_calibration`

#include <*input_analog_axis.h*> Analog axis calibration data structure.

Holds the calibration data for a single analog axis. Initial values are set from the devicetree and can be changed by the applicatoin in runtime using *analog_axis_calibration_set* and *analog_axis_calibration_get*.

Public Members

int16_t `in_min`

Input value that corresponds to the minimum output value.

int16_t `in_max`

Input value that corresponds to the maximum output value.

uint16_t `in_deadzone`

Input value center deadzone.

4.10 Interprocessor Communication (IPC)

4.10.1 IPC service

- *Overview*
- *Simple data exchange*
- *Data exchange using the no-copy API*
  - *Backends*
  - *API Reference*
- *IPC service API*
- *IPC service backend API*

The IPC service API provides an interface to exchange data between two domains or CPUs.

Overview

An IPC service communication channel consists of one instance and one or several endpoints associated with the instance.

An instance is the external representation of a physical communication channel between two domains or CPUs. The actual implementation and internal representation of the instance is peculiar to each backend.

An individual instance is not used to send data between domains/CPUs. To send and receive the data, the user must create (register) an endpoint in the instance. This allows for the connection of the two domains of interest.

It is possible to have zero or multiple endpoints for one single instance, possibly with different priorities, and to use each to exchange data. Endpoint prioritization and multi-instance ability highly depend on the backend used.

The endpoint is an entity the user must use to send and receive data between two domains (connected by the instance). An endpoint is always associated to an instance.

The creation of the instances is left to the backend, usually at init time. The registration of the endpoints is left to the user, usually at run time.

The API does not mandate a way for the backend to create instances but it is strongly recommended to use the devicetree to retrieve the configuration parameters for an instance. Currently, each backend defines its own DT-compatible configuration that is used to configure the interface at boot time.

The following usage scenarios are supported:

- Simple data exchange.
- Data exchange using the no-copy API.

Simple data exchange

To send data between domains or CPUs, an endpoint must be registered onto an instance.

See the following example:

> **Note**
>
> Before registering an endpoint, the instance must be opened using the *ipc_service_open_instance()* function.

```
#include <zephyr/ipc/ipc_service.h>

static void bound_cb(void *priv)
{
   /* Endpoint bounded */
}

static void recv_cb(const void *data, size_t len, void *priv)
{
   /* Data received */
}

static struct ipc_ept_cfg ept0_cfg = {
   .name = "ept0",
   .cb = {
      .bound    = bound_cb,
      .received = recv_cb,
   },
};

int main(void)
{
   const struct device *inst0;
   struct ipc_ept ept0;
   int ret;

   inst0 = DEVICE_DT_GET(DT_NODELABEL(ipc0));
   ret = ipc_service_open_instance(inst0);
   ret = ipc_service_register_endpoint(inst0, &ept0, &ept0_cfg);
```

(continues on next page)

(continued from previous page)

```
   /* Wait for endpoint bound (bound_cb called) */

   unsigned char message[] = "hello world";
   ret = ipc_service_send(&ept0, &message, sizeof(message));
}
```

Data exchange using the no-copy API

If the backend supports the no-copy API you can use it to directly write and read to and from shared memory regions.

See the following example:

```
#include <zephyr/ipc/ipc_service.h>
#include <stdint.h>
#include <string.h>

static struct ipc_ept ept0;

static void bound_cb(void *priv)
{
   /* Endpoint bounded */
}

static void recv_cb_nocopy(const void *data, size_t len, void *priv)
{
   int ret;

   ret = ipc_service_hold_rx_buffer(&ept0, (void *)data);
   /* Process directly or put the buffer somewhere else and release. */
   ret = ipc_service_release_rx_buffer(&ept0, (void *)data);
}

static struct ipc_ept_cfg ept0_cfg = {
   .name = "ept0",
   .cb = {
      .bound    = bound_cb,
      .received = recv_cb,
   },
};

int main(void)
{
   const struct device *inst0;
   int ret;

   inst0 = DEVICE_DT_GET(DT_NODELABEL(ipc0));
   ret = ipc_service_open_instance(inst0);
   ret = ipc_service_register_endpoint(inst0, &ept0, &ept0_cfg);

   /* Wait for endpoint bound (bound_cb called) */
   void *data;
   unsigned char message[] = "hello world";
   uint32_t len = sizeof(message);

   ret = ipc_service_get_tx_buffer(&ept0, &data, &len, K_FOREVER);

   memcpy(data, message, len);
```

(continues on next page)

(continued from previous page)

```
   ret = ipc_service_send_nocopy(&ept0, data, sizeof(message));
}
```

Backends The requirements needed for implementing backends give flexibility to the IPC service. These allow for the addition of dedicated backends having only a subsets of features for specific use cases.

The backend must support at least the following:

- The init-time creation of instances.
- The run-time registration of an endpoint in an instance.

Additionally, the backend can also support the following:

- The run-time deregistration of an endpoint from the instance.
- The run-time closing of an instance.
- The no-copy API.

Each backend can have its own limitations and features that make the backend unique and dedicated to a specific use case. The IPC service API can be used with multiple backends simultaneously, combining the pros and cons of each backend.

ICMsg backend The inter core messaging backend (ICMsg) is a lighter alternative to the heavier RPMsg static vrings backend. It offers a minimal feature set in a small memory footprint. The ICMsg backend is build on top of *Single Producer Single Consumer Packet Buffer*.

Overview The ICMsg backend uses shared memory and MBOX devices for exchanging data. Shared memory is used to store the data, MBOX devices are used to signal that the data has been written.

The backend supports the registration of a single endpoint on a single instance. If the application requires more than one communication channel, you must define multiple instances, each having its own dedicated endpoint.

Configuration The backend is configured via Kconfig and devicetree. When configuring the backend, do the following:

- Define two memory regions and assign them to `tx-region` and `rx-region` of an instance. Ensure that the memory regions used for data exchange are unique (not overlapping any other region) and accessible by both domains (or CPUs).
- Define MBOX devices which are used to send the signal that informs the other domain (or CPU) that data has been written. Ensure that the other domain (or CPU) is able to receive the signal.

See the following configuration example for one of the instances:

```
reserved-memory {
   tx: memory@20070000 {
      reg = <0x20070000 0x0800>;
   };

   rx: memory@20078000 {
      reg = <0x20078000 0x0800>;
   };
```

(continues on next page)

(continued from previous page)

```
};

   ipc {
      ipc0: ipc0 {
         compatible = "zephyr,ipc-icmsg";
         tx-region = <&tx>;
         rx-region = <&rx>;
         mboxes = <&mbox 0>, <&mbox 1>;
         mbox-names = "tx", "rx";
         status = "okay";
      };
   };
};
```

You must provide a similar configuration for the other side of the communication (domain or CPU) but you must swap the MBOX channels and memory regions (`tx-region` and `rx-region`).

Bonding When the endpoint is registered, the following happens on each domain (or CPU) connected through the IPC instance:

1. The domain (or CPU) writes a magic number to its `tx-region` of the shared memory. #. It then sends a signal to the other domain or CPU, informing that the data has been written. Sending the signal to the other domain or CPU is repeated with timeout specified by `CONFIG_IPC_SERVICE_ICMSG_BOND_NOTIFY_REPEAT_TO_MS` option. #. When the signal from the other domain or CPU is received, the magic number is read from `rx-region`. If it is correct, the bonding process is finished and the backend informs the application by calling *`ipc_service_cb.bound`* callback.

Samples

- ipc-icmsg

ICMsg with dynamically allocated buffers backend This backend is built on top of the *ICMsg backend*. Data transferred over this backend travels in dynamically allocated buffers on shared memory. The ICMsg just sends references to the buffers. It also supports multiple endpoints.

This architecture allows for overcoming some common problems with other backends (mostly related to multithread access and zero-copy). This backend provides an alternative with no significant limitations.

Overview The shared memory is divided into two parts. One is reserved for the ICMsg and the other contains equal-sized blocks. The number of blocks is configured in the devicetree.

The data sending process is following:

- The sender allocates one or more blocks. If there are not enough sequential blocks, it waits using the timeout provided in the parameter that also includes K_FOREVER and K_NO_WAIT.
- The allocated blocks are filled with data. For the zero-copy case, this is done by the caller, otherwise, it is copied automatically. During this time other threads are not blocked in any way as long as there are enough free blocks for them. They can allocate, send data and receive data.
- A message containing the block index is sent over ICMsg to the receiver. The size of the ICMsg queue is large enough to hold messages for all blocks, so it will never overflow.

- The receiver can hold the data as long as desired. Again, other threads are not blocked as long as there are enough free blocks for them.
- When data is no longer needed, the backend sends a release message over ICMsg.
- When the backend receives this message, it deallocates all blocks. It is done internally by the backend and it is invisible to the caller.

Configuration The backend is configured using Kconfig and devicetree. When configuring the backend, do the following:

- Define two memory regions and assign them to `tx-region` and `rx-region` of an instance. Ensure that the memory regions used for data exchange are unique (not overlapping any other region) and accessible by both domains (or CPUs).
- Define the number of allocable blocks for each region with `tx-blocks` and `rx-blocks`.
- Define MBOX devices for sending a signal that informs the other domain (or CPU) of the written data. Ensure that the other domain (or CPU) can receive the signal.

See the following configuration example for one of the instances:

```
reserved-memory {
   tx: memory@20070000 {
      reg = <0x20070000 0x0800>;
   };

   rx: memory@20078000 {
      reg = <0x20078000 0x0800>;
   };
};

ipc {
   ipc0: ipc0 {
      compatible = "zephyr,ipc-icbmsg";
      tx-region = <&tx>;
      rx-region = <&rx>;
      tx-blocks = <16>;
      rx-blocks = <32>;
      mboxes = <&mbox 0>, <&mbox 1>;
      mbox-names = "tx", "rx";
      status = "okay";
   };
};
```

You must provide a similar configuration for the other side of the communication (domain or CPU). Swap the MBOX channels, memory regions (`tx-region` and `rx-region`), and block count (`tx-blocks` and `rx-blocks`).

Samples

- ipc_multi_endpoint_sample

API Reference

IPC service API

group `ipc_service_api`

IPC Service API.

Functions

int `ipc_service_open_instance`(const struct *device* *instance)

Open an instance.

Function to be used to open an instance before being able to register a new endpoint on it.

Parameters

- `instance` – **[in]** Instance to open.

Return values

- `-EINVAL` – when instance configuration is invalid.
- `-EIO` – when no backend is registered.
- `-EALREADY` – when the instance is already opened (or being opened).
- `0` – on success or when not implemented on the backend (not needed).
- `other` – errno codes depending on the implementation of the backend.

int `ipc_service_close_instance`(const struct *device* *instance)

Close an instance.

Function to be used to close an instance. All bounded endpoints must be deregistered using ipc_service_deregister_endpoint before this is called.

Parameters

- `instance` – **[in]** Instance to close.

Return values

- `-EINVAL` – when instance configuration is invalid.
- `-EIO` – when no backend is registered.
- `-EALREADY` – when the instance is not already opened.
- `-EBUSY` – when an endpoint exists that hasn't been deregistered
- `0` – on success or when not implemented on the backend (not needed).
- `other` – errno codes depending on the implementation of the backend.

int `ipc_service_register_endpoint`(const struct *device* *instance, struct *ipc_ept* *ept, const struct *ipc_ept_cfg* *cfg)

Register IPC endpoint onto an instance.

Registers IPC endpoint onto an instance to enable communication with a remote device.

The same function registers endpoints for both host and remote devices.

Note

Keep the variable pointed by `cfg` alive when endpoint is in use.

Parameters

- `instance` – **[in]** Instance to register the endpoint onto.
- `ept` – **[in]** Endpoint object.
- `cfg` – **[in]** Endpoint configuration.

Return values

- `-EIO` – when no backend is registered.
- `-EINVAL` – when instance, endpoint or configuration is invalid.
- `-EBUSY` – when the instance is busy.
- `0` – on success.
- `other` – errno codes depending on the implementation of the backend.

int `ipc_service_deregister_endpoint`(struct *ipc_ept* *ept)

Deregister an IPC endpoint from its instance.

Deregisters an IPC endpoint from its instance.

The same function deregisters endpoints for both host and remote devices.

Parameters

- `ept` – **[in]** Endpoint object.

Return values

- `-EIO` – when no backend is registered.
- `-EINVAL` – when instance, endpoint or configuration is invalid.
- `-ENOENT` – when the endpoint is not registered with the instance.
- `-EBUSY` – when the instance is busy.
- `0` – on success.
- `other` – errno codes depending on the implementation of the backend.

int `ipc_service_send`(struct *ipc_ept* *ept, const void *data, size_t len)

Send data using given IPC endpoint.

Parameters

- `ept` – **[in]** Registered endpoint by *ipc_service_register_endpoint*.
- `data` – **[in]** Pointer to the buffer to send.
- `len` – **[in]** Number of bytes to send.

Return values

- `-EIO` – when no backend is registered or send hook is missing from backend.
- `-EINVAL` – when instance or endpoint is invalid.
- `-ENOENT` – when the endpoint is not registered with the instance.
- `-EBADMSG` – when the data is invalid (i.e. invalid data format, invalid length, ...)
- `-EBUSY` – when the instance is busy.
- `-ENOMEM` – when no memory / buffers are available.
- `bytes` – number of bytes sent.
- `other` – errno codes depending on the implementation of the backend.

int `ipc_service_get_tx_buffer_size`(struct *ipc_ept* *ept)

Get the TX buffer size.

Get the maximal size of a buffer which can be obtained by *ipc_service_get_tx_buffer*

Parameters

- `ept` – **[in]** Registered endpoint by *ipc_service_register_endpoint*.

Return values

- `-EIO` – when no backend is registered or send hook is missing from backend.
- `-EINVAL` – when instance or endpoint is invalid.
- `-ENOENT` – when the endpoint is not registered with the instance.
- `-ENOTSUP` – when the operation is not supported by backend.
- `size` – TX buffer size on success.
- `other` – errno codes depending on the implementation of the backend.

int `ipc_service_get_tx_buffer`(struct *ipc_ept* *ept, void **data, uint32_t *size, *k_timeout_t* wait)

Get an empty TX buffer to be sent using *ipc_service_send_nocopy*.

This function can be called to get an empty TX buffer so that the application can directly put its data into the sending buffer without copy from an application buffer.

It is the application responsibility to correctly fill the allocated TX buffer with data and passing correct parameters to *ipc_service_send_nocopy* function to perform data no-copy-send mechanism.

The size parameter can be used to request a buffer with a certain size:

- if the size can be accommodated the function returns no errors and the buffer is allocated
- if the requested size is too big, the function returns -ENOMEM and the the buffer is not allocated.
- if the requested size is '0' the buffer is allocated with the maximum allowed size.

In all the cases on return the size parameter contains the maximum size for the returned buffer.

When the function returns no errors, the buffer is intended as allocated and it is released under two conditions: (1) when sending the buffer using *ipc_service_send_nocopy* (and in this case the buffer is automatically released by the backend), (2) when using *ipc_service_drop_tx_buffer* on a buffer not sent.

Parameters

- `ept` – **[in]** Registered endpoint by *ipc_service_register_endpoint*.
- `data` – **[out]** Pointer to the empty TX buffer.
- `size` – **[inout]** Pointer to store the requested TX buffer size. If the function returns -ENOMEM, this parameter returns the maximum allowed size.
- `wait` – **[in]** Timeout waiting for an available TX buffer.

Return values

- `-EIO` – when no backend is registered or send hook is missing from backend.
- `-EINVAL` – when instance or endpoint is invalid.
- `-ENOENT` – when the endpoint is not registered with the instance.
- `-ENOTSUP` – when the operation or the timeout is not supported by backend.
- `-ENOBUFS` – when there are no TX buffers available.

- `-EALREADY` – when a buffer was already claimed and not yet released.
- `-ENOMEM` – when the requested size is too big (and the size parameter contains the maximum allowed size).
- `0` – on success.
- `other` – errno codes depending on the implementation of the backend.

int `ipc_service_drop_tx_buffer`(struct *ipc_ept* *ept, const void *data)

Drop and release a TX buffer.

Drop and release a TX buffer. It is possible to drop only TX buffers obtained by using *ipc_service_get_tx_buffer*.

Parameters

- `ept` – **[in]** Registered endpoint by *ipc_service_register_endpoint*.
- `data` – **[in]** Pointer to the TX buffer.

Return values

- `-EIO` – when no backend is registered or send hook is missing from backend.
- `-EINVAL` – when instance or endpoint is invalid.
- `-ENOENT` – when the endpoint is not registered with the instance.
- `-ENOTSUP` – when this is not supported by backend.
- `-EALREADY` – when the buffer was already dropped.
- `-ENXIO` – when the buffer was not obtained using *ipc_service_get_tx_buffer*
- `0` – on success.
- `other` – errno codes depending on the implementation of the backend.

int `ipc_service_send_nocopy`(struct *ipc_ept* *ept, const void *data, size_t len)

Send data in a TX buffer reserved by *ipc_service_get_tx_buffer* using the given IPC endpoint.

This is equivalent to *ipc_service_send* but in this case the TX buffer has been obtained by using *ipc_service_get_tx_buffer*.

The application has to take the responsibility for getting the TX buffer using *ipc_service_get_tx_buffer* and filling the TX buffer with the data.

After the *ipc_service_send_nocopy* function is issued the TX buffer is no more owned by the sending task and must not be touched anymore unless the function fails and returns an error.

If this function returns an error, *ipc_service_drop_tx_buffer* can be used to drop the TX buffer.

Parameters

- `ept` – **[in]** Registered endpoint by *ipc_service_register_endpoint*.
- `data` – **[in]** Pointer to the buffer to send obtained by *ipc_service_get_tx_buffer*.
- `len` – **[in]** Number of bytes to send.

Return values

- `-EIO` – when no backend is registered or send hook is missing from backend.

- `-EINVAL` – when instance or endpoint is invalid.
- `-ENOENT` – when the endpoint is not registered with the instance.
- `-EBADMSG` – when the data is invalid (i.e. invalid data format, invalid length, ...)
- `-EBUSY` – when the instance is busy.
- `bytes` – number of bytes sent.
- `other` – errno codes depending on the implementation of the backend.

int `ipc_service_hold_rx_buffer`(struct *ipc_ept* *ept, void *data)

Holds the RX buffer for usage outside the receive callback.

Calling this function prevents the receive buffer from being released back to the pool of shmem buffers. This function can be called in the receive callback when the user does not want to copy the message out in the callback itself.

After the message is processed, the application must release the buffer using the *ipc_service_release_rx_buffer* function.

Parameters

- `ept` – **[in]** Registered endpoint by *ipc_service_register_endpoint*.
- `data` – **[in]** Pointer to the RX buffer to hold.

Return values

- `-EIO` – when no backend is registered or release hook is missing from backend.
- `-EINVAL` – when instance or endpoint is invalid.
- `-ENOENT` – when the endpoint is not registered with the instance.
- `-EALREADY` – when the buffer data has been hold already.
- `-ENOTSUP` – when this is not supported by backend.
- `0` – on success.
- `other` – errno codes depending on the implementation of the backend.

int `ipc_service_release_rx_buffer`(struct *ipc_ept* *ept, void *data)

Release the RX buffer for future reuse.

When supported by the backend, this function can be called after the received message has been processed and the buffer can be marked as reusable again.

It is possible to release only RX buffers on which *ipc_service_hold_rx_buffer* was previously used.

Parameters

- `ept` – **[in]** Registered endpoint by *ipc_service_register_endpoint*.
- `data` – **[in]** Pointer to the RX buffer to release.

Return values

- `-EIO` – when no backend is registered or release hook is missing from backend.
- `-EINVAL` – when instance or endpoint is invalid.
- `-ENOENT` – when the endpoint is not registered with the instance.
- `-EALREADY` – when the buffer data has been already released.
- `-ENOTSUP` – when this is not supported by backend.

- `-ENXIO` – when the buffer was not hold before using *ipc_service_hold_rx_buffer*
- `0` – on success.
- `other` – errno codes depending on the implementation of the backend.

struct `ipc_service_cb`

#include <ipc_service.h> Event callback structure.

It is registered during endpoint registration. This structure is part of the endpoint configuration.

Public Members

void (*`bound`)(void *priv)

Bind was successful.

This callback is called when the endpoint binding is successful.

Param priv
[in] Private user data.

void (*`received`)(const void *data, size_t len, void *priv)

New packet arrived.

This callback is called when new data is received.

> **Note**
>
> When *ipc_service_hold_rx_buffer* is not used, the data buffer is to be considered released and available again only when this callback returns.

Param data
[in] Pointer to data buffer.
Param len
[in] Length of *data*.
Param priv
[in] Private user data.

void (*`error`)(const char *message, void *priv)

An error occurred.

Param message
[in] Error message.
Param priv
[in] Private user data.

struct `ipc_ept`

#include <ipc_service.h> Endpoint instance.

Token is not important for user of the API. It is implemented in a specific backend.

Public Members

const struct *device* *`instance`
Instance this endpoint belongs to.

void *`token`
Backend-specific token used to identify an endpoint in an instance.

struct `ipc_ept_cfg`
#include <*ipc_service.h*> Endpoint configuration structure.

Public Members

const char *`name`
Name of the endpoint.

int `prio`
Endpoint priority.

If the backend supports priorities.

struct *ipc_service_cb* `cb`
Event callback structure.

void *`priv`
Private user data.

IPC service backend API

group `ipc_service_backend`
IPC service backend.

struct `ipc_service_backend`
#include <*ipc_service_backend.h*> IPC backend configuration structure.

This structure is used for configuration backend during registration.

Public Members

int (*`open_instance`)(const struct *device* *instance)
Pointer to the function that will be used to open an instance.
Param instance
[in] Instance pointer.
Retval -EALREADY
when the instance is already opened.
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

int (*`close_instance`)(const struct *device* *instance)

Pointer to the function that will be used to close an instance.

Param instance
[in] Instance pointer.
Retval -EALREADY
when the instance is not already inited.
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

int (*`send`)(const struct *device* *instance, void *token, const void *data, size_t len)

Pointer to the function that will be used to send data to the endpoint.

Param instance
[in] Instance pointer.
Param token
[in] Backend-specific token.
Param data
[in] Pointer to the buffer to send.
Param len
[in] Number of bytes to send.
Retval -EINVAL
when instance is invalid.
Retval -ENOENT
when the endpoint is not registered with the instance.
Retval -EBADMSG
when the message is invalid.
Retval -EBUSY
when the instance is busy or not ready.
Retval -ENOMEM
when no memory / buffers are available.
Retval bytes
number of bytes sent.
Retval other
errno codes depending on the implementation of the backend.

int (*`register_endpoint`)(const struct *device* *instance, void **token, const struct *ipc_ept_cfg* *cfg)

Pointer to the function that will be used to register endpoints.

Param instance
[in] Instance to register the endpoint onto.
Param token
[out] Backend-specific token.
Param cfg
[in] Endpoint configuration.
Retval -EINVAL
when the endpoint configuration or instance is invalid.
Retval -EBUSY
when the instance is busy or not ready.
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

int (*`deregister_endpoint`)(const struct *device* *instance, void *token)

Pointer to the function that will be used to deregister endpoints.

Param instance
[in] Instance from which to deregister the endpoint.
Param token
[in] Backend-specific token.
Retval -EINVAL
when the endpoint configuration or instance is invalid.
Retval -ENOENT
when the endpoint is not registered with the instance.
Retval -EBUSY
when the instance is busy or not ready.
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

int (*`get_tx_buffer_size`)(const struct *device* *instance, void *token)

Pointer to the function that will return the TX buffer size.
Param instance
[in] Instance pointer.
Param token
[in] Backend-specific token.
Retval -EINVAL
when instance is invalid.
Retval -ENOENT
when the endpoint is not registered with the instance.
Retval -ENOTSUP
when the operation is not supported.
Retval size
TX buffer size on success.
Retval other
errno codes depending on the implementation of the backend.

int (*`get_tx_buffer`)(const struct *device* *instance, void *token, void **data, uint32_t *len, *k_timeout_t* wait)

Pointer to the function that will return an empty TX buffer.
Param instance
[in] Instance pointer.
Param token
[in] Backend-specific token.
Param data
[out] Pointer to the empty TX buffer.
Param len
[inout] Pointer to store the TX buffer size.
Param wait
[in] Timeout waiting for an available TX buffer.
Retval -EINVAL
when instance is invalid.
Retval -ENOENT
when the endpoint is not registered with the instance.
Retval -ENOTSUP
when the operation or the timeout is not supported.
Retval -ENOBUFS
when there are no TX buffers available.
Retval -EALREADY
when a buffer was already claimed and not yet released.
Retval -ENOMEM
when the requested size is too big (and the size parameter contains the

maximum allowed size).
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

int (*`drop_tx_buffer`)(const struct *device* *instance, void *token, const void *data)

Pointer to the function that will drop a TX buffer.
Param instance
[in] Instance pointer.
Param token
[in] Backend-specific token.
Param data
[in] Pointer to the TX buffer.
Retval -EINVAL
when instance is invalid.
Retval -ENOENT
when the endpoint is not registered with the instance.
Retval -ENOTSUP
when this function is not supported.
Retval -EALREADY
when the buffer was already dropped.
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

int (*`send_nocopy`)(const struct *device* *instance, void *token, const void *data, size_t len)

Pointer to the function that will be used to send data to the endpoint when the TX buffer has been obtained using *ipc_service_get_tx_buffer*.
Param instance
[in] Instance pointer.
Param token
[in] Backend-specific token.
Param data
[in] Pointer to the buffer to send.
Param len
[in] Number of bytes to send.
Retval -EINVAL
when instance is invalid.
Retval -ENOENT
when the endpoint is not registered with the instance.
Retval -EBADMSG
when the data is invalid (i.e. invalid data format, invalid length, ...)
Retval -EBUSY
when the instance is busy or not ready.
Retval bytes
number of bytes sent.
Retval other
errno codes depending on the implementation of the backend.

int (*`hold_rx_buffer`)(const struct *device* *instance, void *token, void *data)

Pointer to the function that will hold the RX buffer.
Param instance
[in] Instance pointer.

Param token
[in] Backend-specific token.
Param data
[in] Pointer to the RX buffer to hold.
Retval -EINVAL
when instance is invalid.
Retval -ENOENT
when the endpoint is not registered with the instance.
Retval -EALREADY
when the buffer data has been already hold.
Retval -ENOTSUP
when this function is not supported.
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

int (*`release_rx_buffer`)(const struct *device* *instance, void *token, void *data)

Pointer to the function that will release the RX buffer.
Param instance
[in] Instance pointer.
Param token
[in] Backend-specific token.
Param data
[in] Pointer to the RX buffer to release.
Retval -EINVAL
when instance is invalid.
Retval -ENOENT
when the endpoint is not registered with the instance.
Retval -EALREADY
when the buffer data has been already released.
Retval -ENOTSUP
when this function is not supported.
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

4.11 Linkable Loadable Extensions (LLEXT)

The LLEXT subsystem provides a toolbox for extending the functionality of an application at runtime with linkable loadable code.

Extensions are precompiled executables in ELF format that can be verified, loaded, and linked with the main Zephyr binary. Extensions can be manipulated and introspected to some degree, as well as unloaded when no longer needed.

4.11.1 Configuration

The following Kconfig options are available for the LLEXT subsystem:

Heap size

The LLEXT subsystem needs a static heap to be allocated for extension related data. The following option controls this allocation.

`CONFIG_LLEXT_HEAP_SIZE`

Size of the LLEXT heap in kilobytes.

Note

When *user mode* is enabled, the heap size must be large enough to allow the extension sections to be allocated with the alignment required by the architecture.

ELF object type

The LLEXT subsystem supports loading different types of extensions; the type can be set by choosing among the following Kconfig options:

`CONFIG_LLEXT_TYPE_ELF_OBJECT`

Build and expect relocatable files as binary object type for the LLEXT subsystem. A single compiler invocation is used to generate the object file.

`CONFIG_LLEXT_TYPE_ELF_RELOCATABLE`

Build and expect relocatable (partially linked) files as the binary object type for the LLEXT subsystem. These object files are generated by the linker by combining multiple object files into a single one.

`CONFIG_LLEXT_TYPE_ELF_SHAREDLIB`

Build and expect shared libraries as binary object type for the LLEXT subsystem. The standard linking process is used to generate the shared library from multiple object files.

Note

This is not currently supported on ARM architectures.

Minimize allocations

The LLEXT subsystem loading mechanism, by default, uses a seek/read abstraction and copies all data into allocated memory; this is done to allow the extension to be loaded from any storage medium. Sometimes, however, data is already in a buffer in RAM and copying it is not necessary. The following option allows the LLEXT subsystem to optimize memory footprint in this case.

`CONFIG_LLEXT_STORAGE_WRITABLE`

Allow the extension to be loaded by directly referencing section data into the ELF buffer. To be effective, this requires the use of an ELF loader that supports the peek functionality, such as the *`llext_buf_loader`*.

Warning

The application must ensure that the buffer used to load the extension remains allocated until the extension is unloaded.

> **Note**
>
> This will directly modify the contents of the buffer during the link phase. Once the extension is unloaded, the buffer must be reloaded before it can be used again in a call to *llext_load()*.

> **Note**
>
> This is currently required by the Xtensa architecture. Further information on this topic is available on GitHub issue #75341.

Using SLID for symbol lookups

When an extension is loaded, the LLEXT subsystem must find the address of all the symbols residing in the main application that the extension references. To this end, the main binary contains a LLEXT-dedicated symbol table, filled with one symbol-name-to-address mapping entry for each symbol exported by the main application to extensions. This table can then be searched into by the LLEXT linker at extension load time. This process is pretty slow due to the nature of string comparisons, and the size consumed by the table can become significant as the number of exported symbols increases.

`CONFIG_LLEXT_EXPORT_BUILTINS_BY_SLID`

Perform an extra processing step on the Zephyr binary and on all extensions being built, converting every string in the symbol tables to a pointer-sized hash called *Symbol Link Identifier* (SLID), which is stored in the binary.

This speeds up the symbol lookup process by allowing usage of integer-based comparisons rather than string-based ones. Another benefit of SLID-based linking is that storing symbol names in the binary is no longer necessary, which provides a significant decrease in symbol table size.

> **Note**
>
> This option is not currently compatible with the *LLEXT EDK*.

> **Note**
>
> Using a different value for this option in the main binary and in extensions is not supported. For example, if the main application is built with `CONFIG_LLEXT_EXPORT_BUILTINS_BY_SLID=y`, it is forbidden to load an extension that was compiled with `CONFIG_LLEXT_EXPORT_BUILTINS_BY_SLID=n`.

EDK configuration

Options influencing the generation and behavior of the LLEXT EDK are described in *LLEXT EDK Kconfig options*.

4.11.2 Building extensions

The LLEXT subsystem allows for the creation of extensions that can be loaded into a running Zephyr application. When building these extensions, it's very often useful to have access to the headers and compiler flags used by the main Zephyr application.

The easiest path to achieve this is to build the extension as part of the Zephyr application, using the *native Zephyr CMake features*. This will result in a single build providing both the main Zephyr application and the extension(s), which will all automatically be built with the same parameters.

In some cases, involving the full Zephyr build system may not be feasible or convenient; maybe the extension is built using a different compiler suite or as part of a different project altogether. In this case, the extension developer needs to export the headers and compiler flags used by the main Zephyr application. This can be done using the *LLEXT Extension Development Kit*.

Using the Zephyr CMake features

The Zephyr build system provides a set of features that can be used to build extensions as part of the Zephyr application. This is the simplest way to build extensions, as it requires minimal additions to an application build system.

Building the extension An extension can be defined in the app's `CMakeLists.txt` by invoking the `add_llext_target` function, providing the target name, the output and the source files. Usage is similar to the standard `add_custom_target` CMake function:

```
add_llext_target(
    <target_name>
    OUTPUT <ext_file.llext>
    SOURCES <src1> [<src2>...]
)
```

where:

- `<target_name>` is the name of the final CMake target that will result in the LLEXT binary being created;
- `<ext_file.llext>` is the name of the output file that will contain the packaged extension;
- `<src1> [<src2>...]` is the list of source files that will be compiled to create the extension.

The exact steps of the extension building process depend on the currently selected *ELF object format*.

The following custom properties of `<target_name>` are defined and can be retrieved using the `get_target_property()` CMake function:

`lib_target`

Target name for the source compilation and/or link step.

`lib_output`

The binary file resulting from compilation and/or linking steps.

`pkg_input`

The file to be used as input for the packaging step.

`pkg_output`

The final extension file name.

Tweaking the build process The following CMake functions can be used to modify the build system behavior during the extension build process to a fine degree. Each of the below functions takes the LLEXT target name as its first argument; it is otherwise functionally equivalent to the common Zephyr `target_*` version.

- `llext_compile_definitions`
- `llext_compile_features`
- `llext_compile_options`
- `llext_include_directories`
- `llext_link_options`

Custom build steps The `add_llext_command` CMake function can be used to add custom build steps that will be executed during the extension build process. The command will be run at the specified build step and can refer to the properties of the target for build-specific details.

The function signature is:

```
add_llext_command(
    TARGET <target_name>
    [PRE_BUILD | POST_BUILD | POST_PKG]
    COMMAND <command> [args...]
)
```

The different build steps are:

`PRE_BUILD`

: Before the extension code is linked, if the architecture uses dynamic libraries. This step can access *lib_target* and its own properties.

`POST_BUILD`

: After the extension code is built, but before packaging it in an `.llext` file. This step is expected to create a *pkg_input* file by reading the contents of *lib_output*.

`POST_PKG`

: After the extension output file has been created. The command can operate on the final llext file *pkg_output*.

Anything else after `COMMAND` will be passed to `add_custom_command()` as-is (including multiple commands and other options).

LLEXT Extension Development Kit (EDK)

When building extensions as a standalone project, outside of the main Zephyr build system, it's important to have access to the same set of generated headers and compiler flags used by the main Zephyr application, since they have a direct impact on how Zephyr headers are interpreted and the extension is compiled in general.

This can be achieved by asking Zephyr to generate an Extension Development Kit (EDK) from the build artifacts of the main Zephyr application, by running the following command which uses the `llext-edk` target:

```
west build -t llext-edk
```

The generated EDK can be found in the build directory under the `zephyr` directory. It's a tarball that contains the headers and compile flags needed to build extensions. The extension developer can then include the headers and use the compile flags in their build system to build the extension.

Compile flags The EDK includes the convenience files `cmake.cflags` (for CMake-based projects) and `Makefile.cflags` (for Make-based ones), which define a set of variables that contain the compile flags needed by the project. The full list of flags needed to build an extension is provided by `LLEXT_CFLAGS`. Also provided is a more granular set of flags that can be used in support of different use cases, such as when building mocks for unit tests:

`LLEXT_INCLUDE_CFLAGS`

Compiler flags to add directories containing non-autogenerated headers to the compiler's include search paths.

`LLEXT_GENERATED_INCLUDE_CFLAGS`

Compiler flags to add directories containing autogenerated headers to the compiler's include search paths.

`LLEXT_ALL_INCLUDE_CFLAGS`

Compiler flags to add all directories containing headers used in the build to the compiler's include search paths. This is a combination of `LLEXT_INCLUDE_CFLAGS` and `LLEXT_GENERATED_INCLUDE_CFLAGS`.

`LLEXT_GENERATED_IMACROS_CFLAGS`

Compiler flags for autogenerated headers that must be included in the build via `-imacros`.

`LLEXT_BASE_CFLAGS`

Other compiler flags that control code generation for the target CPU. None of these flags are included in the above lists.

`LLEXT_CFLAGS`

All flags required to build an extension. This is a combination of `LLEXT_ALL_INCLUDE_CFLAGS`, `LLEXT_GENERATED_IMACROS_CFLAGS` and `LLEXT_BASE_CFLAGS`.

LLEXT EDK Kconfig options The LLEXT EDK can be configured using the following Kconfig options:

`CONFIG_LLEXT_EDK_NAME`
The name of the generated EDK tarball.

`CONFIG_LLEXT_EDK_USERSPACE_ONLY`
If set, the EDK will include headers that do not contain code to route syscalls to the kernel. This is useful when building extensions that will run exclusively in user mode.

EDK Sample Refer to llext-edk for an example of how to use the LLEXT EDK.

4.11.3 Loading extensions

Once an extension is built and the ELF file is available, it can be loaded into the Zephyr application using the LLEXT API, which provides a way to load the extension into memory, access its symbols and call its functions.

Loading an extension

An extension may be loaded using any implementation of a *`llext_loader`* which has a set of function pointers that provide the necessary functionality to read the ELF data. A loader also provides

some minimal context (memory) needed by the *llext_load()* function. An implementation over a buffer containing an ELF in addressable memory in memory is available as *llext_buf_loader*.

The extensions are loaded with a call to the *llext_load()* function, passing in the extension name and the configured loader. Once that completes successfully, the extension is loaded into memory and is ready to be used.

> **Note**
>
> When *User Mode* is enabled, the extension will not be included in any user memory domain. To allow access from user mode, the *llext_add_domain()* function must be called.

Accessing code and data

To interact with the newly loaded extension, the host application must use the *llext_find_sym()* function to get the address of the exported symbol. The returned `void *` can then be cast to the appropriate type and used.

A wrapper for calling a function with no arguments is provided in *llext_call_fn()*.

Cleaning up after use

The *llext_unload()* function must be called to free the memory used by the extension once it is no longer required. After this call completes, all pointers to symbols in the extension that were obtained will be invalid.

4.11.4 Troubleshooting

This feature is being actively developed and as such it is possible that some issues may arise. Since linking does modify the binary code, in case of errors the results are difficult to predict. Some common issues may be:

- Results from *llext_find_sym()* point to an invalid address;
- Constants and variables defined in the extension do not have the expected values;
- Calling a function defined in an extension results in a hard fault, or memory in the main application is corrupted after returning from it.

If any of this happens, the following tips may help understand the issue:

- Make sure `CONFIG_LLEXT_LOG_LEVEL` is set to `DEBUG`, then obtain a log of the *llext_load()* invocation.
- If possible, disable memory protection (MMU/MPU) and see if this results in different behavior.
- Try to simplify the extension to the minimum possible code that reproduces the issue.
- Use a debugger to inspect the memory and registers to try to understand what is happening.

> **Note**
>
> When using GDB, the `add_symbol_file` command may be used to load the debugging information and symbols from the ELF file. Make sure to specify the proper offset (usually the start of the `.text` section, reported as `region 0` in the debug logs.)

If the issue persists, please open an issue in the GitHub repository, including all the above information.

4.11.5 API Reference

group `llext_apis`

Since
3.5

Version
0.1.0

Defines

`LLEXT_LOAD_PARAM_DEFAULT`
Default initializer for *llext_load_param*.

Enums

enum `llext_mem`
List of memory regions stored or referenced in the LLEXT subsystem.

This enum lists the different types of memory regions that are used by the LLEXT subsystem. The names match common ELF file section names; but note that at load time multiple ELF sections with similar flags may be merged together into a single memory region.

Values:

enumerator `LLEXT_MEM_TEXT`
Executable code.

enumerator `LLEXT_MEM_DATA`
Initialized data.

enumerator `LLEXT_MEM_RODATA`
Read-only data.

enumerator `LLEXT_MEM_BSS`
Uninitialized data.

enumerator `LLEXT_MEM_EXPORT`
Exported symbol table.

enumerator `LLEXT_MEM_SYMTAB`
Symbol table.

enumerator `LLEXT_MEM_STRTAB`
Symbol name strings.

enumerator LLEXT_MEM_SHSTRTAB
Section name strings.

enumerator LLEXT_MEM_COUNT
Number of regions managed by LLEXT.

Functions

struct *llext* *llext_by_name(const char *name)
Find an llext by name.

Parameters
- name – **[in]** String name of the llext

Returns
a pointer to the *llext*, or NULL if not found

int llext_iterate(int (*fn)(struct *llext* *ext, void *arg), void *arg)
Iterate over all loaded extensions.

Calls a provided callback function for each registered extension or until the callback function returns a non-0 value.

Parameters
- fn – **[in]** callback function
- arg – **[in]** a private argument to be provided to the callback function

Return values
0 – if no extensions are registered

Returns
the value returned by the last callback invocation

int llext_load(struct *llext_loader* *loader, const char *name, struct *llext* **ext, struct *llext_load_param* *ldr_parm)
Load and link an extension.

Loads relevant ELF data into memory and provides a structure to work with it.

Parameters
- loader – **[in]** An extension loader that provides input data and context
- name – **[in]** A string identifier for the extension
- ext – **[out]** Pointer to the newly allocated *llext* structure
- ldr_parm – **[in]** Optional advanced load parameters (may be NULL)

Return values
- -ENOMEM – Not enough memory
- -ENOEXEC – Invalid ELF stream
- -ENOTSUP – Unsupported ELF features

Returns
the previous extension use count on success, or a negative error code.

int **llext_unload**(struct *llext* **ext)

Unload an extension.

Parameters

- **ext** – **[in]** Extension to unload

const void ***llext_find_sym**(const struct *llext_symtable* *sym_table, const char *sym_name)

Find the address for an arbitrary symbol.

Searches for a symbol address, either in the list of symbols exported by the main Zephyr binary or in an extension's symbol table.

Parameters

- **sym_table** – **[in]** Symbol table to lookup symbol in, or `NULL` to search in the main Zephyr symbol table
- **sym_name** – **[in]** Symbol name to find

Returns

the address of symbol in memory, or `NULL` if not found

int **llext_call_fn**(struct *llext* *ext, const char *sym_name)

Call a function by name.

Expects a symbol representing a `void fn(void)` style function exists and may be called.

Parameters

- **ext** – **[in]** Extension to call function in
- **sym_name** – **[in]** Function name (exported symbol) in the extension

Return values

- **0** – Success
- **-ENOENT** – Symbol name not found

int **llext_add_domain**(struct *llext* *ext, struct *k_mem_domain* *domain)

Add an extension to a memory domain.

Allows an extension to be executed in user mode threads when memory protection hardware is enabled by adding memory partitions covering the extension's memory regions to a memory domain.

Parameters

- **ext** – **[in]** Extension to add to a domain
- **domain** – **[in]** Memory domain to add partitions to

Return values

-ENOSYS – `CONFIG_USERSPACE` is not enabled or supported

Returns

0 on success, or a negative error code.

int **arch_elf_relocate**(elf_rela_t *rel, uintptr_t loc, uintptr_t sym_base_addr, const char *sym_name, uintptr_t load_bias)

Architecture specific opcode update function.

ELF files include sections describing a series of *relocations*, which are instructions on how to rewrite opcodes given the actual placement of some symbolic data such as a section, function, or object. These relocations are architecture specific and each architecture supporting LLEXT must implement this.

Parameters

- `rel` – **[in]** Relocation data provided by ELF
- `loc` – **[in]** Address of opcode to rewrite
- `sym_base_addr` – **[in]** Address of symbol referenced by relocation
- `sym_name` – **[in]** Name of symbol referenced by relocation
- `load_bias` – **[in]** `.text` load address

Return values

- `0` – Success
- `-ENOTSUP` – Unsupported relocation
- `-ENOEXEC` – Invalid relocation

ssize_t `llext_find_section`(struct *llext_loader* *loader, const char *search_name)

Locates an ELF section in the file.

Searches for a section by name in the ELF file and returns its offset.

Parameters

- `loader` – Extension loader data and context
- `search_name` – Section name to search for

Returns

the section offset or a negative error code

void `arch_elf_relocate_local`(struct *llext_loader* *loader, struct *llext* *ext, const elf_rela_t *rel, const elf_sym_t *sym, size_t got_offset)

Architecture specific function for updating addresses via relocation table.

Parameters

- `loader` – **[in]** Extension loader data and context
- `ext` – **[in]** Extension to call function in
- `rel` – **[in]** Relocation data provided by elf
- `sym` – **[in]** Corresponding symbol table entry
- `got_offset` – **[in]** Offset within a relocation table

struct `llext`

#include <*llext.h*> Structure describing a linkable loadable extension.

This structure holds the data for a loaded extension. It is created by the *llext_load* function and destroyed by the *llext_unload* function.

Public Members

char `name`[16]

Name of the llext.

void *`mem`[*LLEXT_MEM_COUNT*]

Lookup table of memory regions.

bool `mem_on_heap`[*LLEXT_MEM_COUNT*]

Is the memory for this region allocated on heap?

size_t **mem_size**[*LLEXT_MEM_COUNT*]

Size of each stored region.

size_t **alloc_size**

Total llext allocation size.

struct *llext_symtable* **sym_tab**

Table of all global symbols in the extension; used internally as part of the linking process.

E.g. if the extension is built out of several files, if any symbols are referenced between files, this table will be used to link them.

struct *llext_symtable* **exp_tab**

Table of symbols exported by the llext via *LL_EXTENSION_SYMBOL*.

This can be used in the main Zephyr binary to find symbols in the extension.

unsigned int **use_count**

Extension use counter, prevents unloading while in use.

struct **llext_load_param**

#include <*llext.h*> Advanced llext_load parameters.

This structure contains advanced parameters for *llext_load*.

Public Members

bool **relocate_local**

Perform local relocation.

bool **pre_located**

Use the virtual symbol addresses from the ELF, not addresses within the memory buffer, when calculating relocation targets.

group **llext_symbols**

Defines

EXPORT_SYMBOL(x)

Export a constant symbol to extensions.

Takes a symbol (function or object) by symbolic name and adds the name and address of the symbol to a table of symbols that may be referenced by extensions.

Parameters

- **x** – Symbol to export to extensions

LL_EXTENSION_SYMBOL(x)

Exports a symbol from an extension to the base image.

This macro can be used in extensions to add a symbol (function or object) to the extension's exported symbol table, so that it may be referenced by the base image.

Parameters

- `x` – Extension symbol to export to the base image

struct `llext_const_symbol`

#include <*symbol.h*> Constant symbols are unchangeable named memory addresses.

Symbols may be named function or global objects that have been exported for linking. These constant symbols are useful in the base image as they may be placed in ROM.

> **Note**
>
> When updating this structure, make sure to also update the 'scripts/build/llext_prepare_exptab.py' build script.

Public Members

const char *const `name`

Name of symbol.

const uintptr_t `slid`

Symbol Link Identifier.

`union llext_const_symbol`

At build time, we always write to 'name'.

At runtime, which field is used depends on CONFIG_LLEXT_EXPORT_BUILTINS_BY_SLID.

const void *const `addr`

Address of symbol.

struct `llext_symbol`

#include <*symbol.h*> Symbols are named memory addresses.

Symbols may be named function or global objects that have been exported for linking. These are mutable and should come from extensions where the location may need updating depending on where memory is placed.

Public Members

const char *`name`

Name of symbol.

void *`addr`

Address of symbol.

struct `llext_symtable`

#include <*symbol.h*> A symbol table.

An array of symbols

Public Members

size_t **sym_cnt**
Number of symbols in the table.

struct *llext_symbol* ***syms**
Array of symbols.

group **llext_loader_apis**

Defines

LLEXT_BUF_LOADER(_buf, _buf_len)
Initializer for an *llext_buf_loader* structure.

Parameters

- **_buf** – Buffer containing the ELF binary
- **_buf_len** – Buffer length in bytes

struct **llext_buf_loader**
#include <buf_loader.h> Implementation of *llext_loader* that reads from a memory buffer.

Public Members

struct *llext_loader* **loader**
Extension loader.

struct **llext_loader**
#include <loader.h> Linkable loadable extension loader context.

This object is used to access the ELF file data and cache its contents while an extension is being loaded by the LLEXT subsystem. Once the extension is loaded, this object is no longer needed.

Public Members

int (***read**)(struct *llext_loader* *ldr, void *out, size_t len)
Function to read (copy) from the loader.

Copies len bytes into buf from the current position of the loader.

Param ldr
[in] Loader
Param out
[in] Output location
Param len
[in] Length to copy into the output location
Return
0 on success, or a negative error code.

int (*seek)(struct *llext_loader* *ldr, size_t pos)

Function to seek to a new absolute location in the stream.

Changes the location of the loader position to a new absolute given position.

Param ldr
[in] Loader
Param pos
[in] Position in stream to move loader
Return
0 on success, or a negative error code.

void *(*peek)(struct *llext_loader* *ldr, size_t pos)

Optional function to peek at an absolute location in the ELF.

Return a pointer to the buffer at specified offset.

Param ldr
[in] Loader
Param pos
[in] Position to obtain a pointer to
Return
a pointer into the buffer or `NULL` if not supported

Note

The LLEXT subsystem requires architecture-specific support. It is currently available only on ARM and Xtensa cores.

4.12 Logging

- *Global Kconfig Options*
- *Usage*
  - *Logging in a module*
  - *Logging in a module instance*
  - *Controlling the logging*
- *Logging panic*
- *Printk*
- *Architecture*
  - *Default Frontend*
  - *Custom Frontend*
  - *Logging strings*
  - *Multi-domain support*
  - *Logging backends*
  - *Dictionary-based Logging*
- *Recommendations*

- *Benchmark*
- *Stack usage*
- *API Reference*
  - *Logger API*
  - *Logger control*
  - *Log message*
  - *Logger backend interface*
  - *Logger output formatting*

The logging API provides a common interface to process messages issued by developers. Messages are passed through a frontend and are then processed by active backends. Custom frontend and backends can be used if needed.

Summary of the logging features:

- Deferred logging reduces the time needed to log a message by shifting time consuming operations to a known context instead of processing and sending the log message when called.
- Multiple backends supported (up to 9 backends).
- Custom frontend support. It can work together with backends.
- Compile time filtering on module level.
- Run time filtering independent for each backend.
- Additional run time filtering on module instance level.
- Timestamping with user provided function. Timestamp can have 32 or 64 bits.
- Dedicated API for dumping data.
- Dedicated API for handling transient strings.
- Panic support - in panic mode logging switches to blocking, synchronous processing.
- Printk support - printk message can be redirected to the logging.
- Design ready for multi-domain/multi-processor system.
- Support for logging floating point variables and long long arguments.
- Built-in copying of transient strings used as arguments.
- Support for multi-domain logging.

Logging API is highly configurable at compile time as well as at run time. Using Kconfig options (see *Global Kconfig Options*) logs can be gradually removed from compilation to reduce image size and execution time when logs are not needed. During compilation logs can be filtered out on module basis and severity level.

Logs can also be compiled in but filtered on run time using dedicate API. Run time filtering is independent for each backend and each source of log messages. Source of log messages can be a module or specific instance of the module.

There are four severity levels available in the system: error, warning, info and debug. For each severity level the logging API (include/zephyr/logging/log.h) has set of dedicated macros. Logger API also has macros for logging data.

For each level the following set of macros are available:

- `LOG_X` for standard printf-like messages, e.g. *`LOG_ERR`*.

- LOG_HEXDUMP_X for dumping data, e.g. *LOG_HEXDUMP_WRN*.
- LOG_INST_X for standard printf-like message associated with the particular instance, e.g. *LOG_INST_INF*.
- LOG_INST_HEXDUMP_X for dumping data associated with the particular instance, e.g. *LOG_INST_HEXDUMP_DBG*

The warning level also exposes the following additional macro:

- *LOG_WRN_ONCE* for warnings where only the first occurrence is of interest.

There are two configuration categories: configurations per module and global configuration. When logging is enabled globally, it works for modules. However, modules can disable logging locally. Every module can specify its own logging level. The module must define the LOG_LEVEL macro before using the API. Unless a global override is set, the module logging level will be honored. The global override can only increase the logging level. It cannot be used to lower module logging levels that were previously set higher. It is also possible to globally limit logs by providing maximal severity level present in the system, where maximal means lowest severity (e.g. if maximal level in the system is set to info, it means that errors, warnings and info levels are present but debug messages are excluded).

Each module which is using the logging must specify its unique name and register itself to the logging. If module consists of more than one file, registration is performed in one file but each file must define a module name.

Logger's default frontend is designed to be thread safe and minimizes time needed to log the message. Time consuming operations like string formatting or access to the transport are not performed by default when logging API is called. When logging API is called a message is created and added to the list. Dedicated, configurable buffer for pool of log messages is used. There are 2 types of messages: standard and hexdump. Each message contain source ID (module or instance ID and domain ID which might be used for multiprocessor systems), timestamp and severity level. Standard message contains pointer to the string and arguments. Hexdump message contains copied data and string.

4.12.1 Global Kconfig Options

These options can be found in the following path subsys/logging/Kconfig.

CONFIG_LOG: Global switch, turns on/off the logging.

Mode of operations:

CONFIG_LOG_MODE_DEFERRED: Deferred mode.

CONFIG_LOG_MODE_IMMEDIATE: Immediate (synchronous) mode.

CONFIG_LOG_MODE_MINIMAL: Minimal footprint mode.

Filtering options:

CONFIG_LOG_RUNTIME_FILTERING: Enables runtime reconfiguration of the filtering.

CONFIG_LOG_DEFAULT_LEVEL: Default level, sets the logging level used by modules that are not setting their own logging level.

CONFIG_LOG_OVERRIDE_LEVEL: It overrides module logging level when it is not set or set lower than the override value.

CONFIG_LOG_MAX_LEVEL: Maximal (lowest severity) level which is compiled in.

Processing options:

CONFIG_LOG_MODE_OVERFLOW: When new message cannot be allocated, oldest one are discarded.

CONFIG_LOG_BLOCK_IN_THREAD: If enabled and new log message cannot be allocated thread context will block for up to CONFIG_LOG_BLOCK_IN_THREAD_TIMEOUT_MS or until log message is allocated.

CONFIG_LOG_PRINTK: Redirect printk calls to the logging.

CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD: When the number of buffered log messages reaches the threshold, the dedicated thread (see *log_thread_set()*) is woken up. If CONFIG_LOG_PROCESS_THREAD is enabled then this threshold is used by the internal thread.

CONFIG_LOG_PROCESS_THREAD: When enabled, logging thread is created which handles log processing.

CONFIG_LOG_PROCESS_THREAD_STARTUP_DELAY_MS: Delay in milliseconds after which logging thread is started.

CONFIG_LOG_BUFFER_SIZE: Number of bytes dedicated for the circular packet buffer.

CONFIG_LOG_FRONTEND: Direct logs to a custom frontend.

CONFIG_LOG_FRONTEND_ONLY: No backends are used when messages goes to frontend.

CONFIG_LOG_FRONTEND_OPT_API: Optional API optimized for the most common simple messages.

CONFIG_LOG_CUSTOM_HEADER: Injects an application provided header into log.h

CONFIG_LOG_TIMESTAMP_64BIT: 64 bit timestamp.

CONFIG_LOG_SIMPLE_MSG_OPTIMIZE: Optimizes simple log messages for size and performance. Option available only for 32 bit architectures.

Formatting options:

CONFIG_LOG_FUNC_NAME_PREFIX_ERR: Prepend standard ERROR log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_WRN: Prepend standard WARNING log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_INF: Prepend standard INFO log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_DBG: Prepend standard DEBUG log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_BACKEND_SHOW_COLOR: Enables coloring of errors (red) and warnings (yellow).

CONFIG_LOG_BACKEND_FORMAT_TIMESTAMP: If enabled timestamp is formatted to *hh:mm:ss:mmm,uuu*. Otherwise is printed in raw format.

Backend options:

CONFIG_LOG_BACKEND_UART: Enabled built-in UART backend.

4.12.2 Usage

Logging in a module

In order to use logging in the module, a unique name of a module must be specified and module must be registered using *LOG_MODULE_REGISTER*. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if custom log level is not provided.

```
#include <zephyr/logging/log.h>
LOG_MODULE_REGISTER(foo, CONFIG_FOO_LOG_LEVEL);
```

If the module consists of multiple files, then LOG_MODULE_REGISTER() should appear in exactly one of them. Each other file should use *LOG_MODULE_DECLARE* to declare its membership in the module. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if custom log level is not provided.

```
#include <zephyr/logging/log.h>
/* In all files comprising the module but one */
LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);
```

In order to use logging API in a function implemented in a header file *LOG_MODULE_DECLARE* macro must be used in the function body before logging API is called. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if custom log level is not provided.

```
#include <zephyr/logging/log.h>

static inline void foo(void)
{
	LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);

	LOG_INF("foo");
}
```

Dedicated Kconfig template (subsys/logging/Kconfig.template.log_config) can be used to create local log level configuration.

Example below presents usage of the template. As a result CONFIG_FOO_LOG_LEVEL will be generated:

```
module = FOO
module-str = foo
source "subsys/logging/Kconfig.template.log_config"
```

Logging in a module instance

In case of modules which are multi-instance and instances are widely used across the system enabling logs will lead to flooding. The logger provides the tools which can be used to provide filtering on instance level rather than module level. In that case logging can be enabled for particular instance.

In order to use instance level filtering following steps must be performed:

- a pointer to specific logging structure is declared in instance structure. LOG_INSTANCE_PTR_DECLARE is used for that.

```
#include <zephyr/logging/log_instance.h>

struct foo_object {
	LOG_INSTANCE_PTR_DECLARE(log);
	uint32_t id;
}
```

- module must provide macro for instantiation. In that macro, logging instance is registered and log instance pointer is initialized in the object structure.

```
#define FOO_OBJECT_DEFINE(_name)                              \
	LOG_INSTANCE_REGISTER(foo, _name, CONFIG_FOO_LOG_LEVEL) \
	struct foo_object _name = {                           \
		LOG_INSTANCE_PTR_INIT(log, foo, _name)        \
	}
```

Note that when logging is disabled logging instance and pointer to that instance are not created.

In order to use the instance logging API in a source file, a compile-time log level must be set using *LOG_LEVEL_SET*.

```
LOG_LEVEL_SET(CONFIG_FOO_LOG_LEVEL);

void foo_init(foo_object *f)
{
     LOG_INST_INF(f->log, "Initialized.");
}
```

In order to use the instance logging API in a header file, a compile-time log level must be set using *LOG_LEVEL_SET*.

```
static inline void foo_init(foo_object *f)
{
     LOG_LEVEL_SET(CONFIG_FOO_LOG_LEVEL);

     LOG_INST_INF(f->log, "Initialized.");
}
```

Controlling the logging

By default, logging processing in deferred mode is handled internally by the dedicated task which starts automatically. However, it might not be available if multithreading is disabled. It can also be disabled by unsetting CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD. In that case, logging can be controlled using the API defined in include/zephyr/logging/log_ctrl.h. Logging must be initialized before it can be used. Optionally, the user can provide a function which returns the timestamp value. If not provided, k_cycle_get or *k_cycle_get_32* is used for timestamping. The *log_process()* function is used to trigger processing of one log message (if pending), and returns true if there are more messages pending. However, it is recommended to use macro wrappers (*LOG_INIT* and *LOG_PROCESS*) which handle the case where logging is disabled.

The following snippet shows how logging can be processed in simple forever loop.

```
#include <zephyr/logging/log_ctrl.h>

int main(void)
{
     LOG_INIT();
     /* If multithreading is enabled provide thread id to the logging. */
     log_thread_set(k_current_get());

     while (1) {
             if (LOG_PROCESS() == false) {
                     /* sleep */
             }
     }
}
```

If logs are processed from a thread (user or internal) then it is possible to enable a feature which will wake up processing thread when certain amount of log messages are buffered (see CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD).

4.12.3 Logging panic

In case of error condition system usually can no longer rely on scheduler or interrupts. In that situation deferred log message processing is not an option. Logger controlling API provides a

function for entering into panic mode (*log_panic()*) which should be called in such situation.

When *log_panic()* is called, _panic_ notification is sent to all active backends. Once all backends are notified, all buffered messages are flushed. Since that moment all logs are processed in a blocking way.

4.12.4 Printk

Typically, logging and `printk()` use the same output, which they compete for. This can lead to issues if the output does not support preemption but it may also result in corrupted output because logging data is interleaved with printk data. However, it is possible to redirect printk messages to the logging subsystem by enabling `CONFIG_LOG_PRINTK`. In that case, printk entries are treated as log messages with level 0 (they cannot be disabled). When enabled, logging manages the output so there is no interleaving. However, in deferred mode the printk behaviour is changed since the output is delayed until the logging thread processes the data. `CONFIG_LOG_PRINTK` is enabled by default.

4.12.5 Architecture

Logging consists of 3 main parts:

- Frontend
- Core
- Backends

Log message is generated by a source of logging which can be a module or instance of a module.

Default Frontend

Default frontend is engaged when the logging API is called in a source of logging (e.g. *LOG_INF*) and is responsible for filtering a message (compile and run time), allocating a buffer for the message, creating the message and committing that message. Since the logging API can be called in an interrupt, the frontend is optimized to log the message as fast as possible.

Log message A log message contains a message descriptor (source, domain and level), timestamp, formatted string details (see *Cbprintf Packaging*) and optional data. Log messages are stored in a continuous block of memory. Memory is allocated from a circular packet buffer (*Multi Producer Single Consumer Packet Buffer*), which has a few consequences:

- Each message is a self-contained, continuous block of memory thus it is suited for copying the message (e.g. for offline processing).
- Messages must be sequentially freed. Backend processing is synchronous. Backend can make a copy for deferred processing.

A log message has following format:

Message Header	2 bits: MPSC packet buffer header
	1 bit: Trace/Log message flag
	3 bits: Domain ID
	3 bits: Level
	10 bits: Cbprintf Package Length
	12 bits: Data length
	1 bit: Reserved
	pointer: Pointer to the source descriptor[1]
	32 or 64 bits: Timestamp[1]
	Optional padding[2]
Cbprintf package (optional)	Header
	Arguments
	Appended strings
Hexdump data (optional)	
Alignment padding (optional)	

Log message allocation It may happen that the frontend cannot allocate a message. This happens if the system is generating more log messages than it can process in certain time frame. There are two strategies to handle that case:

- No overflow - the new log is dropped if space for a message cannot be allocated.
- Overflow - the oldest pending messages are freed, until the new message can be allocated. Enabled by `CONFIG_LOG_MODE_OVERFLOW`. Note that it degrades performance thus it is recommended to adjust buffer size and amount of enabled logs to limit dropping.

Run-time filtering If run-time filtering is enabled, then for each source of logging a filter structure in RAM is declared. Such filter is using 32 bits divided into ten 3 bit slots. Except *slot 0*, each slot stores current filter for one backend in the system. *Slot 0* (bits 0-2) is used to aggregate maximal filter setting for given source of logging. Aggregate slot determines if log message is created for given entry since it indicates if there is at least one backend expecting that log entry. Backend slots are examined when message is processed by the core to determine if message is accepted by the given backend. Contrary to compile time filtering, binary footprint is increased because logs are compiled in.

In the example below backend 1 is set to receive errors (*slot 1*) and backend 2 up to info level (*slot 2*). Slots 3-9 are not used. Aggregated filter (*slot 0*) is set to info level and up to this level message from that particular source will be buffered.

slot 0	slot 1	slot 2	slot 3	...	slot 9
INF	ERR	INF	OFF	...	OFF

Custom Frontend

Custom frontend is enabled using `CONFIG_LOG_FRONTEND`. Logs are directed to functions declared in include/zephyr/logging/log_frontend.h. If option `CONFIG_LOG_FRONTEND_ONLY` is enabled then log message is not created and no backend is handled. Otherwise, custom frontend can coexist with backends.

[1] Depending on the platform and the timestamp size fields may be swapped.
[2] It may be required for cbprintf package alignment

In some cases, logs need to be redirected at the macro level. For these cases, CONFIG_LOG_CUSTOM_HEADER can be used to inject an application provided header named *zephyr_custom_log.h* at the end of include/zephyr/logging/log.h.

Logging strings

String arguments are handled by *Cbprintf Packaging*. See *Limitations and recommendations* for limitations and recommendations.

Multi-domain support

More complex systems can consist of multiple domains where each domain is an independent binary. Examples of domains are a core in a multicore SoC or one of the binaries (Secure or Nonsecure) on an ARM TrustZone core.

Tracing and debugging on a multi-domain system is more complex and requires an efficient logging system. Two approaches can be used to structure this logging system:

- Log inside each domain independently. This option is not always possible as it requires that each domain has an available backend (for example, UART). This approach can also be troublesome to use and not scalable, as logs are presented on independent outputs.
- Use a multi-domain logging system where log messages from each domain end up in one root domain, where they are processed exactly as in a single domain case. In this approach, log messages are passed between domains using a connection between domains created from the backend on one side and linked to the other.

  The Log link is an interface introduced in this multi-domain approach. The Log link is responsible for receiving any log message from another domain, creating a copy, and putting that local log message copy (including remote data) into the message queue. This specific log link implementation matches the complementary backend implementation to allow log messages exchange and logger control like configuring filtering, getting log source names, and so on.

There are three types of domains in a multi-domain system:

- The *end domain* has the logging core implementation and a cross-domain backend. It can also have other backends in parallel.
- The *relay domain* has one or more links to other domains but does not have backends that output logs to the user. It has a cross-domain backend either to another relay or to the root domain.
- The *root domain* has one or multiple links and a backend that outputs logs to the user.

See the following image for an example of a multi-domain setup:

In this architecture, a link can handle multiple domains. For example, let's consider an SoC with two ARM Cortex-M33 cores with TrustZone: cores A and B (see the example illustrated above). There are four domains in the system, as each core has both a Secure and a Nonsecure domain. If *core A nonsecure* (A_NS) is the root domain, it has two links: one to *core A secure* (A_NS-A_S) and one to *core B nonsecure* (A_NS-B_NS). *B_NS* domain has one link, to *core B secure B_NS-B_S*), and a backend to *A_NS*.

Since in all instances there is a standard logging subsystem, it is always possible to have multiple backends and simultaneously output messages to them. An example of this is shown in the illustration above as a dotted UART backend on the *B_NS* domain.

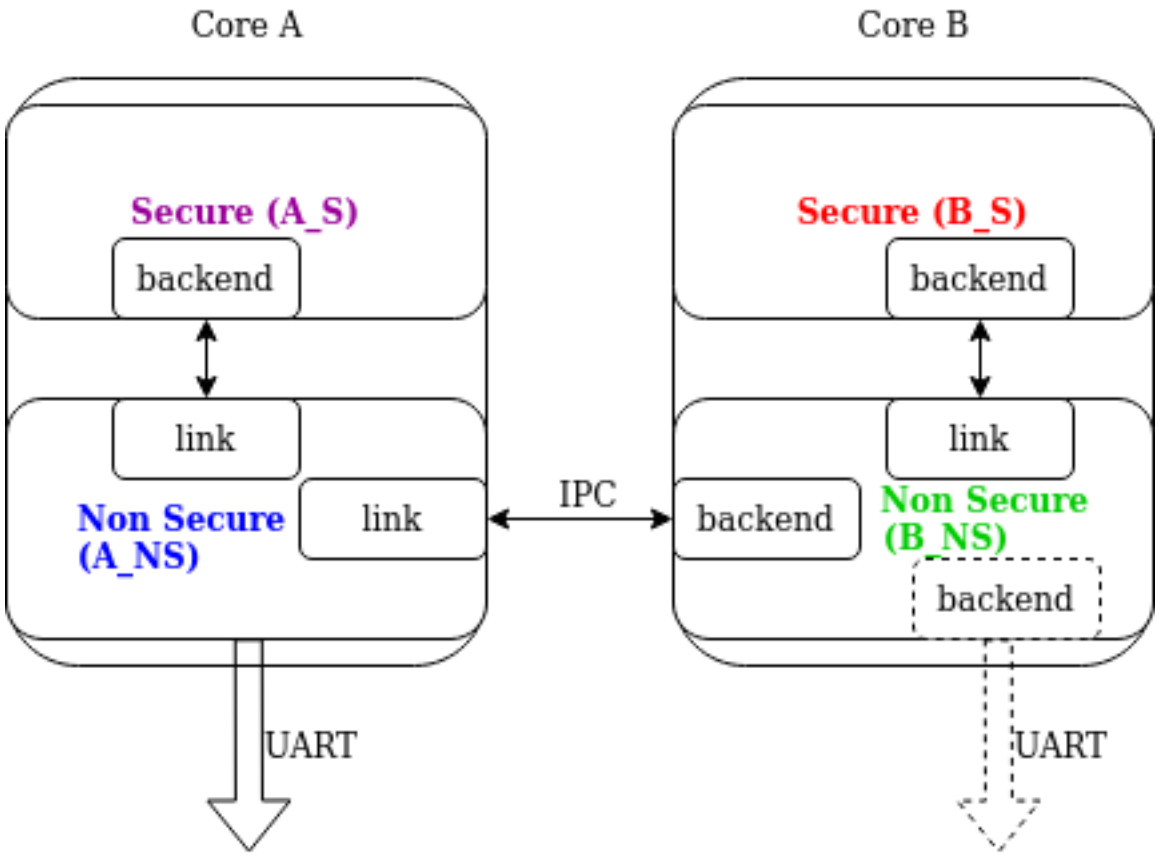

Fig. 5: Multi-domain example

Domain ID The source of each log message can be identified by the following fields in the header: `source_id` and `domain_id`.

The value assigned to the `domain_id` is relative. Whenever a domain creates a log message, it sets its `domain_id` to `0`. When a message crosses the domain, `domain_id` changes as it is increased by the link offset. The link offset is assigned during the initialization, where the logger core is iterating over all the registered links and assigned offsets.

The first link has the offset set to 1. The following offset equals the previous link offset plus the number of domains in the previous link.

The following example is shown below, where the assigned `domain_ids` are shown for each domain:

Let's consider a log message created on the *B_S* domain:

1. Initially, it has its `domain_id` set to `0`.
2. When the *B_NS*-*B_S* link receives the message, it increases the `domain_id` to 1 by adding the *B_NS*-*B_S* offset.
3. The message is passed to *A_NS*.
4. When the *A_NS*-*B_NS* link receives the message, it adds the offset (2) to the `domain_id`. The message ends up with the `domain_id` set to 3, which uniquely identifies the message originator.

Cross-domain log message In most cases, the address space of each domain is unique, and one domain cannot access directly the data in another domain. For this reason, the backend can partially process the message before it is passed to another domain. Partial processing can

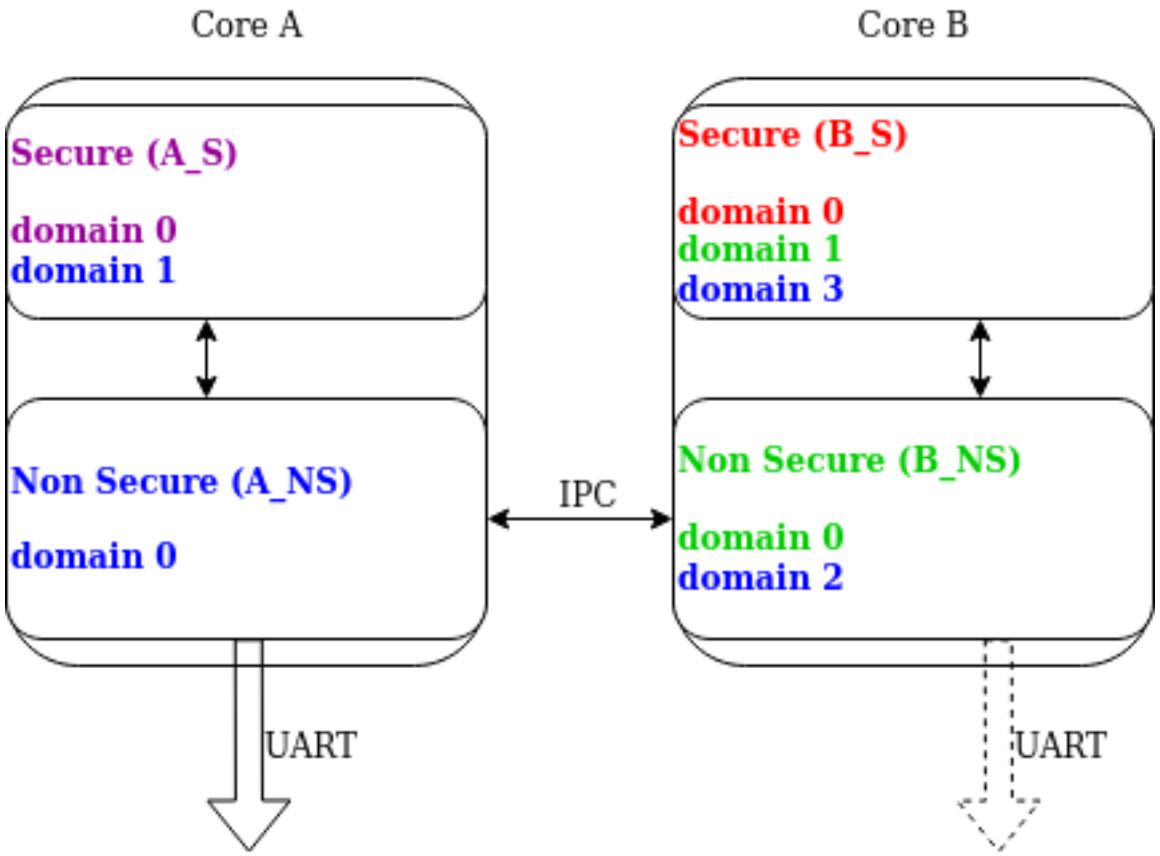

Fig. 6: Domain IDs assigning example

include converting a string package to a *fully self-contained* version (copying read-only strings to the package body).

Each domain can have a different timestamp source in terms of frequency and offset. Logging does not perform any timestamp conversion.

Runtime filtering In the single-domain case, each log source has a dedicated variable with runtime filtering for each backend in the system. In the multi-domain case, the originator of the log message is not aware of the number of backends in the root domain.

As such, to filter logs in multiple domains, each source requires a runtime filtering setting in each domain on the way to the root domain. As the number of sources in other domains is not known during the compilation, the runtime filtering of remote sources must use dynamically allocated memory (one word per source). When a backend in the root domain changes the filtering of the module from a remote domain, the local filter is updated. After the update, the aggregated filter (the maximum from all the local backends) is checked and, if changed, the remote domain is informed about this change. With this approach, the runtime filtering works identically in both multi-domain and single-domain scenarios.

Message ordering Logging does not provide any mechanism for synchronizing timestamps across multiple domains:

- If domains have different timestamp sources, messages will be processed in the order of arrival to the buffer in the root domain.
- If domains have the same timestamp source or if there is an out-of-bound mechanism that recalculates timestamps, there are 2 options:

- Messages are processed as they arrive in the buffer in the root domain. Messages are unordered but they can be sorted by the host as the timestamp indicates the time of the message generation.
- Links have dedicated buffers. During processing, the head of each buffer is checked and the oldest message is processed first.

  With this approach, it is possible to maintain the order of the messages at the cost of a suboptimal memory utilization (since the buffer is not shared) and increased processing latency (see CONFIG_LOG_PROCESSING_LATENCY_US).

Logging backends

Logging backends are registered using *LOG_BACKEND_DEFINE*. The macro creates an instance in the dedicated memory section. Backends can be dynamically enabled (*log_backend_enable()*) and disabled. When *Run-time filtering* is enabled, *log_filter_set()* can be used to dynamically change filtering of a module logs for given backend. Module is identified by source ID and domain ID. Source ID can be retrieved if source name is known by iterating through all registered sources.

Logging supports up to 9 concurrent backends. Log message is passed to the each backend in processing phase. Additionally, backend is notified when logging enter panic mode with *log_backend_panic()*. On that call backend should switch to synchronous, interrupt-less operation or shut down itself if that is not supported. Occasionally, logging may inform backend about number of dropped messages with *log_backend_dropped()*. Message processing API is version specific.

log_backend_msg_process() is used for processing message. It is common for standard and hexdump messages because log message hold string with arguments and data. It is also common for deferred and immediate logging.

Message formatting Logging provides set of function that can be used by the backend to format a message. Helper functions are available in include/zephyr/logging/log_output.h.

Example message formatted using *log_output_msg_process()*.

```
[00:00:00.000,274] <info> sample_instance.inst1: logging message
```

Dictionary-based Logging

Dictionary-based logging, instead of human readable texts, outputs the log messages in binary format. This binary format encodes arguments to formatted strings in their native storage formats which can be more compact than their text equivalents. For statically defined strings (including the format strings and any string arguments), references to the ELF file are encoded instead of the whole strings. A dictionary created at build time contains the mappings between these references and the actual strings. This allows the offline parser to obtain the strings from the dictionary to parse the log messages. This binary format allows a more compact representation of log messages in certain scenarios. However, this requires the use of an offline parser and is not as intuitive to use as text-based log messages.

Note that `long double` is not supported by Python's `struct` module. Therefore, log messages with `long double` will not display the correct values.

Configuration Here are kconfig options related to dictionary-based logging:

- CONFIG_LOG_DICTIONARY_SUPPORT enables dictionary-based logging support. This should be selected by the backends which require it.

- The UART backend can be used for dictionary-based logging. These are additional config for the UART backend:
  - `CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX` tells the UART backend to output hexadecimal characters for dictionary based logging. This is useful when the log data needs to be captured manually via terminals and consoles.
  - `CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_BIN` tells the UART backend to output binary data.

Usage When dictionary-based logging is enabled via enabling related logging backends, a JSON database file, named `log_dictionary.json`, will be created in the build directory. This database file contains information for the parser to correctly parse the log data. Note that this database file only works with the same build, and cannot be used for any other builds.

To use the log parser:

```
./scripts/logging/dictionary/log_parser.py <build dir>/log_dictionary.json <log data file>
```

The parser takes two required arguments, where the first one is the full path to the JSON database file, and the second part is the file containing log data. Add an optional argument `--hex` to the end if the log data file contains hexadecimal characters (e.g. when `CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX=y`). This tells the parser to convert the hexadecimal characters to binary before parsing.

Please refer to the logging-dictionary sample to learn more on how to use the log parser.

4.12.6 Recommendations

The are following recommendations:

- Enable `CONFIG_LOG_SPEED` to slightly speed up deferred logging at the cost of slight increase in memory footprint.
- Compiler with C11 `_Generic` keyword support is recommended. Logging performance is significantly degraded without it. See *Cbprintf Packaging*.
- It is recommended to cast pointer to `const char *` when it is used with `%s` format specifier and it points to a constant string.
- It is recommended to cast pointer to `char *` when it is used with `%s` format specifier and it points to a transient string.
- It is recommended to cast character pointer to non character pointer (e.g., `void *`) when it is used with `%p` format specifier.

```
LOG_WRN("%s", str);
LOG_WRN("%p", (void *)str);
```

4.12.7 Benchmark

Benchmark numbers from tests/subsys/logging/log_benchmark performed on `qemu_x86`. It is a rough comparison to give a general overview.

Feature	
Kernel logging	7us[3]/11us
User logging	13us
kernel logging with overwrite	10us[3]/15us
Logging transient string	42us
Logging transient string from user	50us
Memory utilization[4]	518
Memory footprint (test)[5]	2k
Memory footprint (application)[6]	3.5k
Message footprint[7]	47[3]/32 bytes

Benchmark details

4.12.8 Stack usage

When logging is enabled it impacts stack usage of the context that uses logging API. If stack is optimized it may lead to stack overflow. Stack usage depends on mode and optimization. It also significantly varies between platforms. In general, when `CONFIG_LOG_MODE_DEFERRED` is used stack usage is smaller since logging is limited to creating and storing log message. When `CONFIG_LOG_MODE_IMMEDIATE` is used then log message is processed by the backend which includes string formatting. In case of that mode, stack usage will depend on which backends are used.

tests/subsys/logging/log_stack test is used to characterize stack usage depending on mode, optimization and platform used. Test is using only the default backend.

Some of the platforms characterization for log message with two `integer` arguments listed below:

Platform	Deferred	Deferred (no optimization)	Immediate	Immediate (no optimization)
ARM Cortex-M3	40	152	412	783
x86	12	224	388	796
riscv32	24	208	456	844
xtensa	72	336	504	944
x86_64	32	528	1088	1440

4.12.9 API Reference

[6] Logging subsystem memory footprint in samples/subsys/logging/logger.
[7] Average size of a log message (excluding string) with 2 arguments on `Cortex M3`

Dictionary-based logging
Output binary log data using the dictionary-based logging API.

Logging
Output log messages to the console using the logging subsystem.

group `log_api`

Logger API.

Defines

`LOG_ERR`(...)

Writes an ERROR level message to the log.

It's meant to report severe errors, such as those from which it's not possible to recover.

Parameters

- `...` – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

`LOG_WRN`(...)

Writes a WARNING level message to the log.

It's meant to register messages related to unusual situations that are not necessarily errors.

Parameters

- `...` – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

`LOG_INF`(...)

Writes an INFO level message to the log.

It's meant to write generic user oriented messages.

Parameters

- `...` – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

`LOG_DBG`(...)

Writes a DEBUG level message to the log.

It's meant to write developer oriented information.

Parameters

- `...` – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

`LOG_WRN_ONCE`(...)

Writes a WARNING level message to the log on the first execution only.

It's meant for situations that warrant investigation but could clutter the logs if output on every execution.

Parameters

- `...` – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_PRINTK(...)

Unconditionally print raw log message.

The result is same as if printk was used but it goes through logging infrastructure thus utilizes logging mode, e.g. deferred mode.

Parameters

- ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_RAW(...)

Unconditionally print raw log message.

Provided string is printed as is without appending any characters (e.g., color or newline).

Parameters

- ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_ERR(_log_inst, ...)

Writes an ERROR level message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to report severe errors, such as those from which it's not possible to recover.

Parameters

- **_log_inst** – Pointer to the log structure associated with the instance.
- ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_WRN(_log_inst, ...)

Writes a WARNING level message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to register messages related to unusual situations that are not necessarily errors.

Parameters

- **_log_inst** – Pointer to the log structure associated with the instance.
- ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_INF(_log_inst, ...)

Writes an INFO level message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to write generic user oriented messages.

Parameters

- **_log_inst** – Pointer to the log structure associated with the instance.
- ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_DBG(_log_inst, ...)

Writes a DEBUG level message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to write developer oriented information.

Parameters

- **_log_inst** – Pointer to the log structure associated with the instance.
- **...** – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_HEXDUMP_ERR(_data, _length, _str)

Writes an ERROR level hexdump message to the log.

It's meant to report severe errors, such as those from which it's not possible to recover.

Parameters

- **_data** – Pointer to the data to be logged.
- **_length** – Length of data (in bytes).
- **_str** – Persistent, raw string.

LOG_HEXDUMP_WRN(_data, _length, _str)

Writes a WARNING level message to the log.

It's meant to register messages related to unusual situations that are not necessarily errors.

Parameters

- **_data** – Pointer to the data to be logged.
- **_length** – Length of data (in bytes).
- **_str** – Persistent, raw string.

LOG_HEXDUMP_INF(_data, _length, _str)

Writes an INFO level message to the log.

It's meant to write generic user oriented messages.

Parameters

- **_data** – Pointer to the data to be logged.
- **_length** – Length of data (in bytes).
- **_str** – Persistent, raw string.

LOG_HEXDUMP_DBG(_data, _length, _str)

Writes a DEBUG level message to the log.

It's meant to write developer oriented information.

Parameters

- **_data** – Pointer to the data to be logged.
- **_length** – Length of data (in bytes).
- **_str** – Persistent, raw string.

LOG_INST_HEXDUMP_ERR(_log_inst, _data, _length, _str)

Writes an ERROR hexdump message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to report severe errors, such as those from which it's not possible to recover.

Parameters

- **_log_inst** – Pointer to the log structure associated with the instance.
- **_data** – Pointer to the data to be logged.
- **_length** – Length of data (in bytes).
- **_str** – Persistent, raw string.

LOG_INST_HEXDUMP_WRN(_log_inst, _data, _length, _str)

Writes a WARNING level hexdump message associated with the instance to the log.

It's meant to register messages related to unusual situations that are not necessarily errors.

Parameters

- **_log_inst** – Pointer to the log structure associated with the instance.
- **_data** – Pointer to the data to be logged.
- **_length** – Length of data (in bytes).
- **_str** – Persistent, raw string.

LOG_INST_HEXDUMP_INF(_log_inst, _data, _length, _str)

Writes an INFO level hexdump message associated with the instance to the log.

It's meant to write generic user oriented messages.

Parameters

- **_log_inst** – Pointer to the log structure associated with the instance.
- **_data** – Pointer to the data to be logged.
- **_length** – Length of data (in bytes).
- **_str** – Persistent, raw string.

LOG_INST_HEXDUMP_DBG(_log_inst, _data, _length, _str)

Writes a DEBUG level hexdump message associated with the instance to the log.

It's meant to write developer oriented information.

Parameters

- **_log_inst** – Pointer to the log structure associated with the instance.
- **_data** – Pointer to the data to be logged.
- **_length** – Length of data (in bytes).
- **_str** – Persistent, raw string.

LOG_MODULE_REGISTER(...)

Create module-specific state and register the module with Logger.

This macro normally must be used after including <zephyr/logging/log.h> to complete the initialization of the module.

Module registration can be skipped in two cases:

- The module consists of more than one file, and another file invokes this macro. (*LOG_MODULE_DECLARE()* should be used instead in all of the module's other files.)
- Instance logging is used and there is no need to create module entry. In that case *LOG_LEVEL_SET()* should be used to set log level used within the file.

Macro accepts one or two parameters:

- module name
- optional log level. If not provided then default log level is used in the file.

Example usage:

- *LOG_MODULE_REGISTER(foo, CONFIG_FOO_LOG_LEVEL)*
- *LOG_MODULE_REGISTER(foo)*

See also

LOG_MODULE_DECLARE

Note

The module's state is defined, and the module is registered, only if LOG_LEVEL for the current source file is non-zero or it is not defined and CONFIG_LOG_DEFAULT_LEVEL is non-zero. In other cases, this macro has no effect.

`LOG_MODULE_DECLARE(...)`

Macro for declaring a log module (not registering it).

Modules which are split up over multiple files must have exactly one file use *LOG_MODULE_REGISTER()* to create module-specific state and register the module with the logger core.

The other files in the module should use this macro instead to declare that same state. (Otherwise, *LOG_INF()* etc. will not be able to refer to module-specific state variables.)

Macro accepts one or two parameters:

- module name
- optional log level. If not provided then default log level is used in the file.

Example usage:

- *LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL)*
- *LOG_MODULE_DECLARE(foo)*

See also

LOG_MODULE_REGISTER

Note

The module's state is declared only if LOG_LEVEL for the current source file is non-zero or it is not defined and CONFIG_LOG_DEFAULT_LEVEL is non-zero. In other cases, this macro has no effect.

`LOG_LEVEL_SET`(level)

Macro for setting log level in the file or function where instance logging API is used.

Parameters

- `level` – Level used in file or in function.

Logger control

Related code samples

Logging
Output log messages to the console using the logging subsystem.

Remote syslog
Enable a remote syslog service that sends syslog messages to a remote server

group `log_ctrl`

Logger control API.

Since
1.13

Defines

`LOG_CORE_INIT`()

`LOG_INIT`()

`LOG_PANIC`()

`LOG_PROCESS`()

Typedefs

typedef log_timestamp_t (*`log_timestamp_get_t`)(void)

Functions

void `log_core_init`(void)

Function system initialization of the logger.

Function is called during start up to allow logging before user can explicitly initialize the logger.

void **log_init**(void)

Function for user initialization of the logger.

void **log_thread_trigger**(void)

Trigger the log processing thread to process logs immediately.

> **Note**
>
> Function has no effect when CONFIG_LOG_MODE_IMMEDIATE is set.

void **log_thread_set**(k_tid_t process_tid)

Function for providing thread which is processing logs.

See CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD.

> **Note**
>
> Function has asserts and has no effect when CONFIG_LOG_PROCESS_THREAD is set.

Parameters

- **process_tid** – Process thread id. Used to wake up the thread.

int **log_set_timestamp_func**(*log_timestamp_get_t* timestamp_getter, uint32_t freq)

Function for providing timestamp function.

Parameters

- **timestamp_getter** – Timestamp function.
- **freq** – Timestamping frequency.

Returns

0 on success or error.

void **log_panic**(void)

Switch the logger subsystem to the panic mode.

Returns immediately if the logger is already in the panic mode.

On panic the logger subsystem informs all backends about panic mode. Backends must switch to blocking mode or halt. All pending logs are flushed after switching to panic mode. In panic mode, all log messages must be processed in the context of the call.

bool **log_process**(void)

Process one pending log message.

Return values

- **true** – There are more messages pending to be processed.
- **false** – No messages pending.

uint32_t **log_buffered_cnt**(void)

Return number of buffered log messages.

Returns

Number of currently buffered log messages.

uint32_t **log_src_cnt_get**(uint32_t domain_id)

Get number of independent logger sources (modules and instances)

Parameters

- **domain_id** – Domain ID.

Returns
Number of sources.

const char *log_source_name_get(uint32_t domain_id, uint32_t source_id)

Get name of the source (module or instance).

Parameters

- **domain_id** – Domain ID.
- **source_id** – Source ID.

Returns
Source name or NULL if invalid arguments.

static inline uint8_t log_domains_count(void)

Return number of domains present in the system.

There will be at least one local domain.

Returns
Number of domains.

const char *log_domain_name_get(uint32_t domain_id)

Get name of the domain.

Parameters

- **domain_id** – Domain ID.

Returns
Domain name.

int log_source_id_get(const char *name)

Function for finding source ID based on source name.

Parameters

- **name** – Source name

Returns
Source ID or negative number when source ID is not found.

uint32_t log_filter_get(struct *log_backend* const *const backend, uint32_t domain_id, int16_t source_id, bool runtime)

Get source filter for the provided backend.

Parameters

- **backend** – Backend instance.
- **domain_id** – ID of the domain.
- **source_id** – Source (module or instance) ID.
- **runtime** – True for runtime filter or false for compiled in.

Returns
Severity level.

uint32_t log_filter_set(struct *log_backend* const *const backend, uint32_t domain_id, int16_t source_id, uint32_t level)

Set filter on given source for the provided backend.

Parameters

- **backend** – Backend instance. NULL for all backends (and frontend).
- **domain_id** – ID of the domain.

- `source_id` – Source (module or instance) ID.
- `level` – Severity level.

Returns
Actual level set which may be limited by compiled level. If filter was set for all backends then maximal level that was set is returned.

uint32_t `log_frontend_filter_get`(int16_t source_id, bool runtime)

Get source filter for the frontend.

Parameters

- `source_id` – Source (module or instance) ID.
- `runtime` – True for runtime filter or false for compiled in.

Returns
Severity level.

uint32_t `log_frontend_filter_set`(int16_t source_id, uint32_t level)

Set filter on given source for the frontend.

Parameters

- `source_id` – Source (module or instance) ID.
- `level` – Severity level.

Returns
Actual level set which may be limited by compiled level.

void `log_backend_enable`(struct *log_backend* const *const backend, void *ctx, uint32_t level)

Enable backend with initial maximum filtering level.

Parameters

- `backend` – Backend instance.
- `ctx` – User context.
- `level` – Severity level.

void `log_backend_disable`(struct *log_backend* const *const backend)

Disable backend.

Parameters

- `backend` – Backend instance.

const struct *log_backend* *`log_backend_get_by_name`(const char *backend_name)

Get backend by name.

Parameters

- `backend_name` – **[in]** Name of the backend as defined by the LOG_BACKEND_DEFINE.

Return values
`Pointer` – to the backend instance if found, NULL if backend is not found.

const struct *log_backend* *`log_format_set_all_active_backends`(size_t log_type)

Sets logging format for all active backends.

Parameters

- `log_type` – Log format.

Return values
`Pointer` – to the last backend that failed, NULL for success.

static inline bool `log_data_pending`(void)

Check if there is pending data to be processed by the logging subsystem.

Function can be used to determine if all logs have been flushed. Function returns false when deferred mode is not enabled.

Return values

- `true` – There is pending data.
- `false` – No pending data to process.

int `log_set_tag`(const char *tag)

Configure tag used to prefix each message.

Parameters

- `tag` – Tag.

Return values

- `0` – on successful operation.
- `-ENOTSUP` – if feature is disabled.
- `-ENOMEM` – if string is longer than the buffer capacity. Tag will be trimmed.

int `log_mem_get_usage`(uint32_t *buf_size, uint32_t *usage)

Get current memory usage.

Parameters

- `buf_size` – **[out]** Capacity of the buffer used for storing log messages.
- `usage` – **[out]** Number of bytes currently containing pending log messages.

Return values

- `-EINVAL` – if logging mode does not use the buffer.
- `0` – successfully collected usage data.

int `log_mem_get_max_usage`(uint32_t *max)

Get maximum memory usage.

Requires CONFIG_LOG_MEM_UTILIZATION option.

Parameters

- `max` – **[out]** Maximum number of bytes used for pending log messages.

Return values

- `-EINVAL` – if logging mode does not use the buffer.
- `-ENOTSUP` – if instrumentation is not enabled. not been enabled.
- `0` – successfully collected usage data.

Log message

group `log_msg`

Log message API.

Defines

LOG_MSG_GENERIC_HDR

LOG_MSG_SIMPLE_ARG_CNT_CHECK(...)

LOG_MSG_SIMPLE_ARG_TYPE_CHECK_0(fmt)

LOG_MSG_SIMPLE_ARG_TYPE_CHECK_1(fmt, arg)

LOG_MSG_SIMPLE_ARG_TYPE_CHECK_2(fmt, arg0, arg1)

LOG_MSG_SIMPLE_ARG_TYPE_CHECK(...)

brief Determine if string arguments types allow to use simplified message creation mode.

Parameters

- ... – String with arguments.

LOG_MSG_SIMPLE_CHECK(...)

Check if message can be handled using simplified method.

Following conditions must be met:

- 32 bit platform
- Number of arguments from 0 to 2
- Type of an argument must be a numeric value that fits in 32 bit word.

Parameters

- ... – String with arguments.

Return values

- 1 – if message qualifies.
- 0 – if message does not qualify.

LOG_MSG_SIMPLE_FUNC(_source, _level, ...)

Call specific function to create a log message.

Macro picks matching function (based on number of arguments) and calls it. String arguments are casted to uint32_t.

Parameters

- **_source** – Source.
- **_level** – Severity level.
- ... – String with arguments.

Functions

static inline uint32_t **log_msg_get_total_wlen**(const struct *log_msg_desc* desc)

Get total length (in 32 bit words) of a log message.

Parameters

- **desc** – Log message descriptor.

Returns

Length.

static inline uint32_t **log_msg_generic_get_wlen**(const union mpsc_pbuf_generic *item)

Get length of the log item.

Parameters

- **item** – Item.

Returns
Length in 32 bit words.

static inline uint8_t **log_msg_get_domain**(struct *log_msg* *msg)

Get log message domain ID.

Parameters

- **msg** – Log message.

Returns
Domain ID

static inline uint8_t **log_msg_get_level**(struct *log_msg* *msg)

Get log message level.

Parameters

- **msg** – Log message.

Returns
Log level.

static inline const void ***log_msg_get_source**(struct *log_msg* *msg)

Get message source data.

Parameters

- **msg** – Log message.

Returns
Pointer to the source data.

int16_t **log_msg_get_source_id**(struct *log_msg* *msg)

Get log message source ID.

Parameters

- **msg** – Log message.

Returns
Source ID, or -1 if not available.

static inline log_timestamp_t **log_msg_get_timestamp**(struct *log_msg* *msg)

Get timestamp.

Parameters

- **msg** – Log message.

Returns
Timestamp.

static inline void ***log_msg_get_tid**(struct *log_msg* *msg)

Get Thread ID.

Parameters

- **msg** – Log message.

Returns
Thread ID.

static inline uint8_t *log_msg_get_data(struct *log_msg* *msg, size_t *len)

Get data buffer.

Parameters

- msg – log message.
- len – location where data length is written.

Returns

pointer to the data buffer.

static inline uint8_t *log_msg_get_package(struct *log_msg* *msg, size_t *len)

Get string package.

Parameters

- msg – log message.
- len – location where string package length is written.

Returns

pointer to the package.

Logger backend interface

Related code samples

BLE logging backend
Send log messages over BLE using the BLE logging backend.

Remote syslog
Enable a remote syslog service that sends syslog messages to a remote server

group `log_backend`

Logger backend interface.

Defines

`LOG_BACKEND_DEFINE`(_name, _api, _autostart, ...)

Macro for creating a logger backend instance.

Parameters

- `_name` – Name of the backend instance.
- `_api` – Logger backend API.
- `_autostart` – If true backend is initialized and activated together with the logger subsystem.
- `...` – Optional context.

Enums

enum `log_backend_evt`

Backend events.

Values:

enumerator `LOG_BACKEND_EVT_PROCESS_THREAD_DONE`

Event when process thread finishes processing.

This event is emitted when the process thread finishes processing pending log messages.

Note

This is not emitted when there are no pending log messages being processed.

> **Note**
>
> Deferred mode only.

enumerator LOG_BACKEND_EVT_MAX

Maximum number of backend events.

Functions

static inline void **log_backend_init**(const struct *log_backend* *const backend)

Initialize or initiate the logging backend.

If backend initialization takes longer time it could block logging thread if backend is autostarted. That is because all backends are initialized in the context of the logging thread. In that case, backend shall provide function for polling for readiness (*log_backend_is_ready*).

Parameters

- **backend** – **[in]** Pointer to the backend instance.

static inline int **log_backend_is_ready**(const struct *log_backend* *const backend)

Poll for backend readiness.

If backend is ready immediately after initialization then backend may not provide this function.

Parameters

- **backend** – **[in]** Pointer to the backend instance.

Return values

- **0** – if backend is ready.
- **-EBUSY** – if backend is not yet ready.

static inline void **log_backend_msg_process**(const struct *log_backend* *const backend, union *log_msg_generic* *msg)

Process message.

Function is used in deferred and immediate mode. On return, message content is processed by the backend and memory can be freed.

Parameters

- **backend** – **[in]** Pointer to the backend instance.
- **msg** – **[in]** Pointer to message with log entry.

static inline void **log_backend_dropped**(const struct *log_backend* *const backend, uint32_t cnt)

Notify backend about dropped log messages.

Function is optional.

Parameters

- **backend** – **[in]** Pointer to the backend instance.
- **cnt** – **[in]** Number of dropped logs since last notification.

static inline void **log_backend_panic**(const struct *log_backend* *const backend)

Reconfigure backend to panic mode.

Parameters

- **backend** – **[in]** Pointer to the backend instance.

static inline void **log_backend_id_set**(const struct *log_backend* *const backend, uint8_t id)

Set backend id.

> **Note**
>
> It is used internally by the logger.

Parameters

- **backend** – Pointer to the backend instance.
- **id** – ID.

static inline uint8_t **log_backend_id_get**(const struct *log_backend* *const backend)

Get backend id.

> **Note**
>
> It is used internally by the logger.

Parameters

- **backend** – **[in]** Pointer to the backend instance.

Returns

Id.

static inline const struct *log_backend* ***log_backend_get**(uint32_t idx)

Get backend.

Parameters

- **idx** – **[in]** Pointer to the backend instance.

Returns

Pointer to the backend instance.

static inline int **log_backend_count_get**(void)

Get number of backends.

Returns

Number of backends.

static inline void **log_backend_activate**(const struct *log_backend* *const backend, void *ctx)

Activate backend.

Parameters

- **backend** – **[in]** Pointer to the backend instance.
- **ctx** – **[in]** User context.

static inline void **log_backend_deactivate**(const struct *log_backend* *const backend)

Deactivate backend.

Parameters

- **backend** – **[in]** Pointer to the backend instance.

static inline bool **log_backend_is_active**(const struct *log_backend* *const backend)

Check state of the backend.

Parameters

- **backend** – **[in]** Pointer to the backend instance.

Returns

True if backend is active, false otherwise.

static inline int **log_backend_format_set**(const struct *log_backend* *backend, uint32_t log_type)

Set logging format.

Parameters

- **backend** – Pointer to the backend instance.
- **log_type** – Log format.

Return values

- **-ENOTSUP** – If the backend does not support changing format types.
- **-EINVAL** – If the input is invalid.
- **0** – for success.

static inline void **log_backend_notify**(const struct *log_backend* *const backend, enum *log_backend_evt* event, union *log_backend_evt_arg* *arg)

Notify a backend of an event.

Parameters

- **backend** – Pointer to the backend instance.
- **event** – Event to be notified.
- **arg** – Pointer to the argument(s).

union **log_backend_evt_arg**

#include <*log_backend.h*> Argument(s) for backend events.

Public Members

void ***raw**

Unspecified argument(s).

struct **log_backend_api**

#include <*log_backend.h*> Logger backend API.

struct **log_backend_control_block**

#include <*log_backend.h*> Logger backend control block.

struct `log_backend`

#include <log_backend.h> Logger backend structure.

Logger output formatting

group `log_output`

Log output API.

Unnamed Group

void `log_custom_output_msg_process`(const struct *log_output* *log_output, struct *log_msg* *msg, uint32_t flags)

Custom logging output formatting.

Process log messages from an external output function set with log_custom_output_msg_set

Function is using provided context with the buffer and output function to process formatted string and output the data.

Parameters

- `log_output` – Pointer to the log output instance.
- `msg` – Log message.
- `flags` – Optional flags.

Defines

`LOG_OUTPUT_TEXT`

Supported backend logging format types for use with log_format_set() API to switch log format at runtime.

`LOG_OUTPUT_SYST`

`LOG_OUTPUT_DICT`

`LOG_OUTPUT_CUSTOM`

`LOG_OUTPUT_DEFINE`(_name, _func, _buf, _size)

Create *log_output* instance.

Parameters

- `_name` – Instance name.
- `_func` – Function for processing output data.
- `_buf` – Pointer to the output buffer.
- `_size` – Size of the output buffer.

Typedefs

typedef int (*`log_output_func_t`)(uint8_t *buf, size_t size, void *ctx)

Prototype of the function processing output data.

> **Note**
>
> If the log output function cannot process all of the data, it is its responsibility to mark them as dropped or discarded by returning the corresponding number of bytes dropped or discarded to the caller.

Param buf
The buffer data.

Param size
The buffer size.

Param ctx
User context.

Return
Number of bytes processed, dropped or discarded.

typedef void (*`log_format_func_t`)(const struct *log_output* *output, struct *log_msg* *msg, uint32_t flags)

Typedef of the function pointer table “format_table”.

Param output
Pointer to *log_output* struct.

Param msg
Pointer to *log_msg* struct.

Param flags
Flags used for text formatting options.

Return
Function pointer based on Kconfigs defined for backends.

Functions

log_format_func_t `log_format_func_t_get`(uint32_t log_type)

Declaration of the get routine for function pointer table format_table.

void `log_output_msg_process`(const struct *log_output* *log_output, struct *log_msg* *msg, uint32_t flags)

Process log messages v2 to readable strings.

Function is using provided context with the buffer and output function to process formatted string and output the data.

Parameters

- `log_output` – Pointer to the log output instance.
- `msg` – Log message.
- `flags` – Optional flags. See Log output formatting flags..

void **log_output_process**(const struct *log_output* *log_output, log_timestamp_t timestamp, const char *domain, const char *source, k_tid_t tid, uint8_t level, const uint8_t *package, const uint8_t *data, size_t data_len, uint32_t flags)

Process input data to a readable string.

Parameters

- **log_output** – Pointer to the log output instance.
- **timestamp** – Timestamp.
- **domain** – Domain name string. Can be NULL.
- **source** – Source name string. Can be NULL.
- **tid** – Thread ID.
- **level** – Criticality level.
- **package** – Cbprintf package with a logging message string.
- **data** – Data passed to hexdump API. Can be NULL.
- **data_len** – Data length.
- **flags** – Formatting flags. See Log output formatting flags..

void **log_output_msg_syst_process**(const struct *log_output* *log_output, struct *log_msg* *msg, uint32_t flags)

Process log messages v2 to SYS-T format.

Function is using provided context with the buffer and output function to process formatted string and output the data in sys-t log output format.

Parameters

- **log_output** – Pointer to the log output instance.
- **msg** – Log message.
- **flags** – Optional flags. See Log output formatting flags..

void **log_output_dropped_process**(const struct *log_output* *output, uint32_t cnt)

Process dropped messages indication.

Function prints error message indicating lost log messages.

Parameters

- **output** – Pointer to the log output instance.
- **cnt** – Number of dropped messages.

void **log_output_flush**(const struct *log_output* *output)

Flush output buffer.

Parameters

- **output** – Pointer to the log output instance.

static inline void **log_output_ctx_set**(const struct *log_output* *output, void *ctx)

Function for setting user context passed to the output function.

Parameters

- **output** – Pointer to the log output instance.
- **ctx** – User context.

static inline void **log_output_hostname_set**(const struct *log_output* *output, const char *hostname)

Function for setting hostname of this device.

Parameters

- **output** – Pointer to the log output instance.
- **hostname** – Hostname of this device

void **log_output_timestamp_freq_set**(uint32_t freq)

Set timestamp frequency.

Parameters

- **freq** – Frequency in Hz.

uint64_t **log_output_timestamp_to_us**(log_timestamp_t timestamp)

Convert timestamp of the message to us.

Parameters

- **timestamp** – Message timestamp

Returns

Timestamp value in us.

struct **log_output_control_block**

#include <*log_output.h*>

struct **log_output**

#include <*log_output.h*> Log_output instance structure.

4.13 Tracing

4.13.1 Overview

The tracing feature provides hooks that permits you to collect data from your application and allows tools running on a host to visualize the inner-working of the kernel and various subsystems.

Every system has application-specific events to trace out. Historically, that has implied:

1. Determining the application-specific payload,
2. Choosing suitable serialization-format,
3. Writing the on-target serialization code,
4. Deciding on and writing the I/O transport mechanics,
5. Writing the PC-side deserializer/parser,
6. Writing custom ad-hoc tools for filtering and presentation.

An application can use one of the existing formats or define a custom format by overriding the macros declared in include/zephyr/tracing/tracing.h.

Different formats, transports and host tools are available and supported in Zephyr.

In fact, I/O varies greatly from system to system. Therefore, it is instructive to create a taxonomy for I/O types when we must ensure the interface between payload/format (Top Layer) and the transport mechanics (bottom Layer) is generic and efficient enough to model these. See the *I/O taxonomy* section below.

4.13.2 Serialization Formats

Common Trace Format (CTF) Support

Common Trace Format, CTF, is an open format and language to describe trace formats. This enables tool reuse, of which line-textual (babeltrace) and graphical (TraceCompass) variants already exist.

CTF should look familiar to C programmers but adds stronger typing. See CTF - A Flexible, High-performance Binary Trace Format.

CTF allows us to formally describe application specific payload and the serialization format, which enables common infrastructure for host tools and parsers and tools for filtering and presentation.

A Generic Interface In CTF, an event is serialized to a packet containing one or more fields. As seen from *I/O taxonomy* section below, a bottom layer may:

- perform actions at transaction-start (e.g. mutex-lock),
- process each field in some way (e.g. sync-push emit, concat, enqueue to thread-bound FIFO),
- perform actions at transaction-stop (e.g. mutex-release, emit of concat buffer).

CTF Top-Layer Example The CTF_EVENT macro will serialize each argument to a field:

```
/* Example for illustration */
static inline void ctf_top_foo(uint32_t thread_id, ctf_bounded_string_t name)
{
  CTF_EVENT(
    CTF_LITERAL(uint8_t, 42),
    thread_id,
    name,
    "hello, I was emitted from function: ",
    __func__  /* __func__ is standard since C99 */
  );
}
```

How to serialize and emit fields as well as handling alignment, can be done internally and statically at compile-time in the bottom-layer.

The CTF top layer is enabled using the configuration option `CONFIG_TRACING_CTF` and can be used with the different transport backends both in synchronous and asynchronous modes.

SEGGER SystemView Support

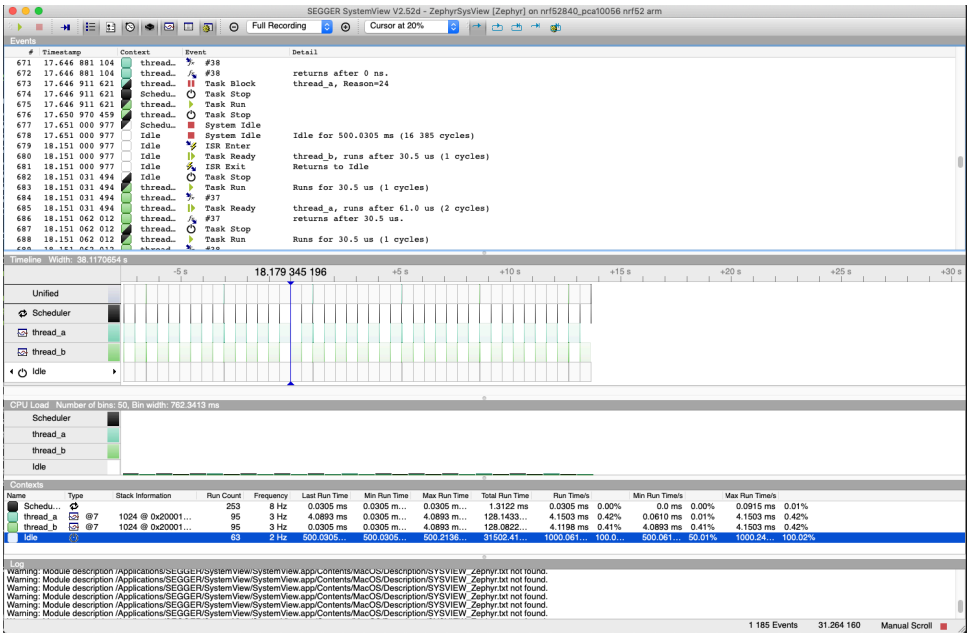
Zephyr provides built-in support for SEGGER SystemView that can be enabled in any application for platforms that have the required hardware support.

The payload and format used with SystemView is custom to the application and relies on RTT as a transport. Newer versions of SystemView support other transports, for example UART or using snapshot mode (both still not supported in Zephyr).

To enable tracing support with SEGGER SystemView add the configuration option `CONFIG_SEGGER_SYSTEMVIEW` to your project configuration file and set it to *y*. For example, this can be added to the synchronization sample to visualize fast switching between threads. SystemView can also be used for post-mortem tracing, which can be enabled with *CONFIG_SEGGER_SYSVIEW_POST_MORTEM_MODE*. In this mode, a debugger can be attached after

the system has crashed using `west attach` after which the latest data from the internal RAM buffer can be loaded into SystemView:

```
CONFIG_STDOUT_CONSOLE=y
# enable to use thread names
CONFIG_THREAD_NAME=y
CONFIG_SEGGER_SYSTEMVIEW=y
CONFIG_USE_SEGGER_RTT=y
CONFIG_TRACING=y
# enable for post-mortem tracing
CONFIG_SEGGER_SYSVIEW_POST_MORTEM_MODE=n
```



Recent versions of SEGGER SystemView come with an API translation table for Zephyr which is incomplete and does not match the current level of support available in Zephyr. To use the latest Zephyr API description table, copy the file available in the tree to your local configuration directory to override the builtin table:

```
# On Linux and MacOS
cp $ZEPHYR_BASE/subsys/tracing/sysview/SYSVIEW_Zephyr.txt ~/.config/SEGGER/
```

User-Defined Tracing

This tracing format allows the user to define functions to perform any work desired when a task is switched in or out, when an interrupt is entered or exited, and when the cpu is idle.

Examples include: - simple toggling of GPIO for external scope tracing while minimizing extra cpu load - generating/outputting trace data in a non-standard or proprietary format that can not be supported by the other tracing systems

The following functions can be defined by the user:

```
void sys_trace_thread_create_user(struct k_thread *thread);
void sys_trace_thread_abort_user(struct k_thread *thread);
void sys_trace_thread_suspend_user(struct k_thread *thread);
void sys_trace_thread_resume_user(struct k_thread *thread);
void sys_trace_thread_name_set_user(struct k_thread *thread);
void sys_trace_thread_switched_in_user(struct k_thread *thread);
void sys_trace_thread_switched_out_user(struct k_thread *thread);
```

(continues on next page)

(continued from previous page)

```
void sys_trace_thread_info_user(struct k_thread *thread);
void sys_trace_thread_sched_ready_user(struct k_thread *thread);
void sys_trace_thread_pend_user(struct k_thread *thread);
void sys_trace_thread_priority_set_user(struct k_thread *thread, int prio);
void sys_trace_isr_enter_user(int nested_interrupts);
void sys_trace_isr_exit_user(int nested_interrupts);
void sys_trace_idle_user();
```

Enable this format with the CONFIG_TRACING_USER option.

4.13.3 Transport Backends

The following backends are currently supported:

- UART
- USB
- File (Using the native port with POSIX architecture based targets)
- RTT (With SystemView)
- RAM (buffer to be retrieved by a debugger)

4.13.4 Using Tracing

The sample samples/subsys/tracing demonstrates tracing with different formats and backends.

To get started, the simplest way is to use the CTF format with the native_sim port, build the sample as follows:

Using west:

```
west build -b native_sim samples/subsys/tracing -- -DCONF_FILE=prj_native_ctf.conf
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=native_sim -DCONF_FILE=prj_native_ctf.conf samples/subsys/
↪tracing

# Now run the build tool on the generated build system:
ninja -Cbuild
```

You can then run the resulting binary with the option `-trace-file` to generate the tracing data:

```
mkdir data
cp $ZEPHYR_BASE/subsys/tracing/ctf/tsdl/metadata data/
./build/zephyr/zephyr.exe -trace-file=data/channel0_0
```

The resulting CTF output can be visualized using babeltrace or TraceCompass by pointing the tool to the data directory with the metadata and trace files.

Using RAM backend

For devices that do not have available I/O for tracing such as USB or UART but have enough RAM to collect trace data, the ram backend can be enabled with configuration CONFIG_TRACING_BACKEND_RAM. Adjust CONFIG_RAM_TRACING_BUFFER_SIZE to be able to record enough

traces for your needs. Then thanks to a runtime debugger such as gdb this buffer can be fetched from the target to an host computer:

```
(gdb) dump binary memory data/channel0_0 <ram_tracing_start> <ram_tracing_end>
```

The resulting channel0_0 file have to be placed in a directory with the `metadata` file like the other backend.

4.13.5 Visualisation Tools

TraceCompass

TraceCompass is an open source tool that visualizes CTF events such as thread scheduling and interrupts, and is helpful to find unintended interactions and resource conflicts on complex systems.

See also the presentation by Ericsson, Advanced Trouble-shooting Of Real-time Systems.

4.13.6 Future LTTng Inspiration

Currently, the top-layer provided here is quite simple and bare-bones, and needlessly copied from Zephyr's Segger SystemView debug module.

For an OS like Zephyr, it would make sense to draw inspiration from Linux's LTTng and change the top-layer to serialize to the same format. Doing this would enable direct reuse of TraceCompass' canned analyses for Linux. Alternatively, LTTng-analyses in TraceCompass could be customized to Zephyr. It is ongoing work to enable TraceCompass visibility of Zephyr in a target-agnostic and open source way.

I/O Taxonomy

- Atomic Push/Produce/Write/Enqueue:
  - **synchronous:**
    means data-transmission has completed with the return of the call.
  - **asynchronous:**
    means data-transmission is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - **buffered:**
    means data-transmissions are copied and grouped together to form a larger ones. Usually for amortizing overhead (burst dequeue) or jitter-mitigation (steady dequeue).

  Examples:

  - **sync unbuffered**
    E.g. PIO via GPIOs having steady stream, no extra FIFO memory needed. Low jitter but may be less efficient (can't amortize the overhead of writing).
  - **sync buffered**
    E.g. `fwrite()` or enqueuing into FIFO. Blockingly burst the FIFO when its buffer-waterlevel exceeds threshold. Jitter due to bursts may lead to missed deadlines.
  - **async unbuffered**
    E.g. DMA, or zero-copying in shared memory. Be careful of data hazards, race conditions, etc!

  - **async buffered**
    E.g. enqueuing into FIFO.

- Atomic Pull/Consume/Read/Dequeue:
  - **synchronous:**
    means data-reception has completed with the return of the call.
  - **asynchronous:**
    means data-reception is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - **buffered:**
    means data is copied-in in larger chunks than request-size. Usually for amortizing wait-time.

  Examples:

  - **sync unbuffered**
    E.g. Blocking read-call, `fread()` or SPI-read, zero-copying in shared memory.
  - **sync buffered**
    E.g. Blocking read-call with caching applied. Makes sense if read pattern exhibits spatial locality.
  - **async unbuffered**
    E.g. zero-copying in shared memory. Be careful of data hazards, race conditions, etc!
  - **async buffered**
    E.g. `aio_read()` or DMA.

Unfortunately, I/O may not be atomic and may, therefore, require locking. Locking may not be needed if multiple independent channels are available.

- **The system has non-atomic write and one shared channel**
  E.g. UART. Locking required.

  ```
  lock(); emit(a); emit(b); emit(c); release();
  ```

- **The system has non-atomic write but many channels**
  E.g. Multi-UART. Lock-free if the bottom-layer maps each Zephyr thread+ISR to its own channel, thus alleviating races as each thread is sequentially consistent with itself.

  ```
  emit(a,thread_id); emit(b,thread_id); emit(c,thread_id);
  ```

- **The system has atomic write but one shared channel**
  E.g. `native_sim` or board with DMA. May or may not need locking.

  ```
  emit(a ## b ## c); /* Concat to buffer */

  lock(); emit(a); emit(b); emit(c); release(); /* No extra mem */
  ```

- **The system has atomic write and many channels**
  E.g. native_sim or board with multi-channel DMA. Lock-free.

  ```
  emit(a ## b ## c, thread_id);
  ```

4.13.7 Object tracking

The kernel can also maintain lists of objects that can be used to track their usage. Currently, the following lists can be enabled:

```
struct k_timer *_track_list_k_timer;
struct k_mem_slab *_track_list_k_mem_slab;
struct k_sem *_track_list_k_sem;
```

(continues on next page)

(continued from previous page)

```
struct k_mutex *_track_list_k_mutex;
struct k_stack *_track_list_k_stack;
struct k_msgq *_track_list_k_msgq;
struct k_mbox *_track_list_k_mbox;
struct k_pipe *_track_list_k_pipe;
struct k_queue *_track_list_k_queue;
struct k_event *_track_list_k_event;
```

Those global variables are the head of each list - they can be traversed with the help of macro `SYS_PORT_TRACK_NEXT`. For instance, to traverse all initialized mutexes, one can write:

```
struct k_mutex *cur = _track_list_k_mutex;
while (cur != NULL) {
  /* Do something */

  cur = SYS_PORT_TRACK_NEXT(cur);
}
```

To enable object tracking, enable `CONFIG_TRACING_OBJECT_TRACKING`. Note that each list can be enabled or disabled via their tracing configuration. For example, to disable tracking of semaphores, one can disable `CONFIG_TRACING_SEMAPHORE`.

Object tracking is behind tracing configuration as it currently leverages tracing infrastructure to perform the tracking.

4.13.8 API

Common

group **subsys_tracing_apis**

Tracing APIs.

Defines

sys_trace_sys_init_enter(entry, level)

Called when entering an init function.

sys_trace_sys_init_exit(entry, level, result)

Called when exiting an init function.

Functions

void **sys_trace_isr_enter**(void)

Called when entering an ISR.

void **sys_trace_isr_exit**(void)

Called when exiting an ISR.

void **sys_trace_isr_exit_to_scheduler**(void)

Called when exiting an ISR and switching to scheduler.

void **sys_trace_idle**(void)

Called when the cpu enters the idle state.

Threads

group `subsys_tracing_apis_thread`

Thread Tracing APIs.

Defines

`sys_port_trace_k_thread_foreach_enter`()

Called when entering a k_thread_foreach call.

`sys_port_trace_k_thread_foreach_exit`()

Called when exiting a k_thread_foreach call.

`sys_port_trace_k_thread_foreach_unlocked_enter`()

Called when entering a k_thread_foreach_unlocked.

`sys_port_trace_k_thread_foreach_unlocked_exit`()

Called when exiting a k_thread_foreach_unlocked.

`sys_port_trace_k_thread_create`(new_thread)

Trace creating a Thread.

Parameters

- `new_thread` – Thread object

`sys_port_trace_k_thread_user_mode_enter`()

Trace Thread entering user mode.

`sys_port_trace_k_thread_join_enter`(thread, timeout)

Called when entering a k_thread_join.

Parameters

- `thread` – Thread object
- `timeout` – Timeout period

`sys_port_trace_k_thread_join_blocking`(thread, timeout)

Called when k_thread_join blocks.

Parameters

- `thread` – Thread object
- `timeout` – Timeout period

`sys_port_trace_k_thread_join_exit`(thread, timeout, ret)

Called when exiting k_thread_join.

Parameters

- `thread` – Thread object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_thread_sleep_enter`(timeout)

Called when entering k_thread_sleep.

Parameters

- `timeout` – Timeout period

`sys_port_trace_k_thread_sleep_exit`(timeout, ret)
Called when exiting k_thread_sleep.

Parameters

- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_thread_msleep_enter`(ms)
Called when entering k_thread_msleep.

Parameters

- `ms` – Duration in milliseconds

`sys_port_trace_k_thread_msleep_exit`(ms, ret)
Called when exiting k_thread_msleep.

Parameters

- `ms` – Duration in milliseconds
- `ret` – Return value

`sys_port_trace_k_thread_usleep_enter`(us)
Called when entering k_thread_usleep.

Parameters

- `us` – Duration in microseconds

`sys_port_trace_k_thread_usleep_exit`(us, ret)
Called when exiting k_thread_usleep.

Parameters

- `us` – Duration in microseconds
- `ret` – Return value

`sys_port_trace_k_thread_busy_wait_enter`(usec_to_wait)
Called when entering k_thread_busy_wait.

Parameters

- `usec_to_wait` – Duration in microseconds

`sys_port_trace_k_thread_busy_wait_exit`(usec_to_wait)
Called when exiting k_thread_busy_wait.

Parameters

- `usec_to_wait` – Duration in microseconds

`sys_port_trace_k_thread_yield`()
Called when a thread yields.

`sys_port_trace_k_thread_wakeup`(thread)
Called when a thread wakes up.

Parameters

- `thread` – Thread object

`sys_port_trace_k_thread_start`(thread)
Called when a thread is started.

Parameters

- `thread` – Thread object

sys_port_trace_k_thread_abort(thread)
Called when a thread is being aborted.

Parameters

- thread – Thread object

sys_port_trace_k_thread_abort_enter(thread)
Called when a thread enters the k_thread_abort routine.

Parameters

- thread – Thread object

sys_port_trace_k_thread_abort_exit(thread)
Called when a thread exits the k_thread_abort routine.

Parameters

- thread – Thread object

sys_port_trace_k_thread_priority_set(thread)
Called when setting priority of a thread.

Parameters

- thread – Thread object

sys_port_trace_k_thread_suspend_enter(thread)
Called when a thread enters the k_thread_suspend function.

Parameters

- thread – Thread object

sys_port_trace_k_thread_suspend_exit(thread)
Called when a thread exits the k_thread_suspend function.

Parameters

- thread – Thread object

sys_port_trace_k_thread_resume_enter(thread)
Called when a thread enters the resume from suspension function.

Parameters

- thread – Thread object

sys_port_trace_k_thread_resume_exit(thread)
Called when a thread exits the resumed from suspension function.

Parameters

- thread – Thread object

sys_port_trace_k_thread_sched_lock()
Called when the thread scheduler is locked.

sys_port_trace_k_thread_sched_unlock()
Called when the thread scheduler is unlocked.

sys_port_trace_k_thread_name_set(thread, ret)
Called when a thread name is set.

Parameters

- thread – Thread object
- ret – Return value

`sys_port_trace_k_thread_switched_out`()
Called before a thread has been selected to run.

`sys_port_trace_k_thread_switched_in`()
Called after a thread has been selected to run.

`sys_port_trace_k_thread_ready`(thread)
Called when a thread is ready to run.

Parameters

- `thread` – Thread object

`sys_port_trace_k_thread_pend`(thread)
Called when a thread is pending.

Parameters

- `thread` – Thread object

`sys_port_trace_k_thread_info`(thread)
Provide information about specific thread.

Parameters

- `thread` – Thread object

`sys_port_trace_k_thread_sched_wakeup`(thread)
Trace implicit thread wakeup invocation by the scheduler.

Parameters

- `thread` – Thread object

`sys_port_trace_k_thread_sched_abort`(thread)
Trace implicit thread abort invocation by the scheduler.

Parameters

- `thread` – Thread object

`sys_port_trace_k_thread_sched_priority_set`(thread, prio)
Trace implicit thread set priority invocation by the scheduler.

Parameters

- `thread` – Thread object
- `prio` – Thread priority

`sys_port_trace_k_thread_sched_ready`(thread)
Trace implicit thread ready invocation by the scheduler.

Parameters

- `thread` – Thread object

`sys_port_trace_k_thread_sched_pend`(thread)
Trace implicit thread pend invocation by the scheduler.

Parameters

- `thread` – Thread object

`sys_port_trace_k_thread_sched_resume`(thread)
Trace implicit thread resume invocation by the scheduler.

Parameters

- `thread` – Thread object

`sys_port_trace_k_thread_sched_suspend`(thread)
Trace implicit thread suspend invocation by the scheduler.

Parameters

- `thread` – Thread object

Work Queues

group `subsys_tracing_apis_work`
Work Tracing APIs.

Defines

`sys_port_trace_k_work_init`(work)
Trace initialisation of a Work structure.

Parameters

- `work` – Work structure

`sys_port_trace_k_work_submit_to_queue_enter`(queue, work)
Trace submit work to work queue call entry.

Parameters

- `queue` – Work queue structure
- `work` – Work structure

`sys_port_trace_k_work_submit_to_queue_exit`(queue, work, ret)
Trace submit work to work queue call exit.

Parameters

- `queue` – Work queue structure
- `work` – Work structure
- `ret` – Return value

`sys_port_trace_k_work_submit_enter`(work)
Trace submit work to system work queue call entry.

Parameters

- `work` – Work structure

`sys_port_trace_k_work_submit_exit`(work, ret)
Trace submit work to system work queue call exit.

Parameters

- `work` – Work structure
- `ret` – Return value

`sys_port_trace_k_work_flush_enter`(work)
Trace flush work call entry.

Parameters

- `work` – Work structure

`sys_port_trace_k_work_flush_blocking`(work, timeout)
Trace flush work call blocking.

Parameters

- `work` – Work structure
- `timeout` – Timeout period

`sys_port_trace_k_work_flush_exit`(work, ret)
Trace flush work call exit.

Parameters

- `work` – Work structure
- `ret` – Return value

`sys_port_trace_k_work_cancel_enter`(work)
Trace cancel work call entry.

Parameters

- `work` – Work structure

`sys_port_trace_k_work_cancel_exit`(work, ret)
Trace cancel work call exit.

Parameters

- `work` – Work structure
- `ret` – Return value

`sys_port_trace_k_work_cancel_sync_enter`(work, sync)
Trace cancel sync work call entry.

Parameters

- `work` – Work structure
- `sync` – Sync object

`sys_port_trace_k_work_cancel_sync_blocking`(work, sync)
Trace cancel sync work call blocking.

Parameters

- `work` – Work structure
- `sync` – Sync object

`sys_port_trace_k_work_cancel_sync_exit`(work, sync, ret)
Trace cancel sync work call exit.

Parameters

- `work` – Work structure
- `sync` – Sync object
- `ret` – Return value

Poll

group `subsys_tracing_apis_poll`
Poll Tracing APIs.

Defines

`sys_port_trace_k_poll_api_event_init`(event)
Trace initialisation of a Poll Event.

Parameters

- `event` – Poll Event

`sys_port_trace_k_poll_api_poll_enter`(events)
Trace Polling call start.

Parameters

- `events` – Poll Events

`sys_port_trace_k_poll_api_poll_exit`(events, ret)
Trace Polling call outcome.

Parameters

- `events` – Poll Events
- `ret` – Return value

`sys_port_trace_k_poll_api_signal_init`(signal)
Trace initialisation of a Poll Signal.

Parameters

- `signal` – Poll Signal

`sys_port_trace_k_poll_api_signal_reset`(signal)
Trace resetting of Poll Signal.

Parameters

- `signal` – Poll Signal

`sys_port_trace_k_poll_api_signal_check`(signal)
Trace checking of Poll Signal.

Parameters

- `signal` – Poll Signal

`sys_port_trace_k_poll_api_signal_raise`(signal, ret)
Trace raising of Poll Signal.

Parameters

- `signal` – Poll Signal
- `ret` – Return value

Semaphore

group `subsys_tracing_apis_sem`
Semaphore Tracing APIs.

Defines

`sys_port_trace_k_sem_init`(sem, ret)
Trace initialisation of a Semaphore.

Parameters

- `sem` – Semaphore object
- `ret` – Return value

`sys_port_trace_k_sem_give_enter`(sem)
Trace giving a Semaphore entry.

Parameters

- `sem` – Semaphore object

`sys_port_trace_k_sem_give_exit`(sem)
Trace giving a Semaphore exit.

Parameters

- `sem` – Semaphore object

`sys_port_trace_k_sem_take_enter`(sem, timeout)
Trace taking a Semaphore attempt start.

Parameters

- `sem` – Semaphore object
- `timeout` – Timeout period

`sys_port_trace_k_sem_take_blocking`(sem, timeout)
Trace taking a Semaphore attempt blocking.

Parameters

- `sem` – Semaphore object
- `timeout` – Timeout period

`sys_port_trace_k_sem_take_exit`(sem, timeout, ret)
Trace taking a Semaphore attempt outcome.

Parameters

- `sem` – Semaphore object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_sem_reset`(sem)
Trace resetting a Semaphore.

Parameters

- `sem` – Semaphore object

Mutex

group `subsys_tracing_apis_mutex`
Mutex Tracing APIs.

Defines

`sys_port_trace_k_mutex_init`(mutex, ret)
Trace initialization of Mutex.

Parameters

- `mutex` – Mutex object
- `ret` – Return value

`sys_port_trace_k_mutex_lock_enter`(mutex, timeout)
Trace Mutex lock attempt start.

Parameters

- `mutex` – Mutex object
- `timeout` – Timeout period

`sys_port_trace_k_mutex_lock_blocking`(mutex, timeout)
Trace Mutex lock attempt blocking.

Parameters

- `mutex` – Mutex object
- `timeout` – Timeout period

`sys_port_trace_k_mutex_lock_exit`(mutex, timeout, ret)
Trace Mutex lock attempt outcome.

Parameters

- `mutex` – Mutex object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mutex_unlock_enter`(mutex)
Trace Mutex unlock entry.

Parameters

- `mutex` – Mutex object

`sys_port_trace_k_mutex_unlock_exit`(mutex, ret)
Trace Mutex unlock exit.

Condition Variables

group `subsys_tracing_apis_condvar`
Conditional Variable Tracing APIs.

Defines

`sys_port_trace_k_condvar_init`(condvar, ret)
Trace initialization of Conditional Variable.

Parameters

- `condvar` – Conditional Variable object
- `ret` – Return value

`sys_port_trace_k_condvar_signal_enter`(condvar)
Trace Conditional Variable signaling start.

Parameters

- `condvar` – Conditional Variable object

`sys_port_trace_k_condvar_signal_blocking`(condvar, timeout)
Trace Conditional Variable signaling blocking.

Parameters

- `condvar` – Conditional Variable object
- `timeout` – Timeout period

`sys_port_trace_k_condvar_signal_exit`(condvar, ret)
Trace Conditional Variable signaling outcome.

Parameters

- `condvar` – Conditional Variable object
- `ret` – Return value

`sys_port_trace_k_condvar_broadcast_enter`(condvar)
Trace Conditional Variable broadcast enter.

Parameters

- `condvar` – Conditional Variable object

`sys_port_trace_k_condvar_broadcast_exit`(condvar, ret)
Trace Conditional Variable broadcast exit.

Parameters

- `condvar` – Conditional Variable object
- `ret` – Return value

`sys_port_trace_k_condvar_wait_enter`(condvar)
Trace Conditional Variable wait enter.

Parameters

- `condvar` – Conditional Variable object

`sys_port_trace_k_condvar_wait_exit`(condvar, ret)
Trace Conditional Variable wait exit.

Parameters

- `condvar` – Conditional Variable object
- `ret` – Return value

Queues

group `subsys_tracing_apis_queue`
Queue Tracing APIs.

Defines

sys_port_trace_k_queue_init(queue)
Trace initialization of Queue.

Parameters

- queue – Queue object

sys_port_trace_k_queue_cancel_wait(queue)
Trace Queue cancel wait.

Parameters

- queue – Queue object

sys_port_trace_k_queue_queue_insert_enter(queue, alloc)
Trace Queue insert attempt entry.

Parameters

- queue – Queue object
- alloc – Allocation flag

sys_port_trace_k_queue_queue_insert_blocking(queue, alloc, timeout)
Trace Queue insert attempt blocking.

Parameters

- queue – Queue object
- alloc – Allocation flag
- timeout – Timeout period

sys_port_trace_k_queue_queue_insert_exit(queue, alloc, ret)
Trace Queue insert attempt outcome.

Parameters

- queue – Queue object
- alloc – Allocation flag
- ret – Return value

sys_port_trace_k_queue_append_enter(queue)
Trace Queue append enter.

Parameters

- queue – Queue object

sys_port_trace_k_queue_append_exit(queue)
Trace Queue append exit.

Parameters

- queue – Queue object

sys_port_trace_k_queue_alloc_append_enter(queue)
Trace Queue alloc append enter.

Parameters

- queue – Queue object

sys_port_trace_k_queue_alloc_append_exit(queue, ret)
Trace Queue alloc append exit.

Parameters

- queue – Queue object
- ret – Return value

sys_port_trace_k_queue_prepend_enter(queue)
Trace Queue prepend enter.

Parameters

- queue – Queue object

sys_port_trace_k_queue_prepend_exit(queue)
Trace Queue prepend exit.

Parameters

- queue – Queue object

sys_port_trace_k_queue_alloc_prepend_enter(queue)
Trace Queue alloc prepend enter.

Parameters

- queue – Queue object

sys_port_trace_k_queue_alloc_prepend_exit(queue, ret)
Trace Queue alloc prepend exit.

Parameters

- queue – Queue object
- ret – Return value

sys_port_trace_k_queue_insert_enter(queue)
Trace Queue insert attempt entry.

Parameters

- queue – Queue object

sys_port_trace_k_queue_insert_blocking(queue, timeout)
Trace Queue insert attempt blocking.

Parameters

- queue – Queue object
- timeout – Timeout period

sys_port_trace_k_queue_insert_exit(queue)
Trace Queue insert attempt exit.

Parameters

- queue – Queue object

sys_port_trace_k_queue_append_list_enter(queue)
Trace Queue append list enter.

Parameters

- queue – Queue object

sys_port_trace_k_queue_append_list_exit(queue, ret)
Trace Queue append list exit.

Parameters

- queue – Queue object
- ret – Return value

sys_port_trace_k_queue_merge_slist_enter(queue)
Trace Queue merge slist enter.

Parameters

- queue – Queue object

sys_port_trace_k_queue_merge_slist_exit(queue, ret)
Trace Queue merge slist exit.

Parameters

- queue – Queue object
- ret – Return value

sys_port_trace_k_queue_get_enter(queue, timeout)
Trace Queue get attempt enter.

Parameters

- queue – Queue object
- timeout – Timeout period

sys_port_trace_k_queue_get_blocking(queue, timeout)
Trace Queue get attempt blockings.

Parameters

- queue – Queue object
- timeout – Timeout period

sys_port_trace_k_queue_get_exit(queue, timeout, ret)
Trace Queue get attempt outcome.

Parameters

- queue – Queue object
- timeout – Timeout period
- ret – Return value

sys_port_trace_k_queue_remove_enter(queue)
Trace Queue remove enter.

Parameters

- queue – Queue object

sys_port_trace_k_queue_remove_exit(queue, ret)
Trace Queue remove exit.

Parameters

- queue – Queue object
- ret – Return value

`sys_port_trace_k_queue_unique_append_enter`(queue)
Trace Queue unique append enter.

Parameters

- `queue` – Queue object

`sys_port_trace_k_queue_unique_append_exit`(queue, ret)
Trace Queue unique append exit.

Parameters

- `queue` – Queue object
- `ret` – Return value

`sys_port_trace_k_queue_peek_head`(queue, ret)
Trace Queue peek head.

Parameters

- `queue` – Queue object
- `ret` – Return value

`sys_port_trace_k_queue_peek_tail`(queue, ret)
Trace Queue peek tail.

Parameters

- `queue` – Queue object
- `ret` – Return value

FIFO

group `subsys_tracing_apis_fifo`
FIFO Tracing APIs.

Defines

`sys_port_trace_k_fifo_init_enter`(fifo)
Trace initialization of FIFO Queue entry.

Parameters

- `fifo` – FIFO object

`sys_port_trace_k_fifo_init_exit`(fifo)
Trace initialization of FIFO Queue exit.

Parameters

- `fifo` – FIFO object

`sys_port_trace_k_fifo_cancel_wait_enter`(fifo)
Trace FIFO Queue cancel wait entry.

Parameters

- `fifo` – FIFO object

sys_port_trace_k_fifo_cancel_wait_exit(fifo)
Trace FIFO Queue cancel wait exit.

Parameters

- fifo – FIFO object

sys_port_trace_k_fifo_put_enter(fifo, data)
Trace FIFO Queue put entry.

Parameters

- fifo – FIFO object
- data – Data item

sys_port_trace_k_fifo_put_exit(fifo, data)
Trace FIFO Queue put exit.

Parameters

- fifo – FIFO object
- data – Data item

sys_port_trace_k_fifo_alloc_put_enter(fifo, data)
Trace FIFO Queue alloc put entry.

Parameters

- fifo – FIFO object
- data – Data item

sys_port_trace_k_fifo_alloc_put_exit(fifo, data, ret)
Trace FIFO Queue alloc put exit.

Parameters

- fifo – FIFO object
- data – Data item
- ret – Return value

sys_port_trace_k_fifo_put_list_enter(fifo, head, tail)
Trace FIFO Queue put list entry.

Parameters

- fifo – FIFO object
- head – First ll-node
- tail – Last ll-node

sys_port_trace_k_fifo_put_list_exit(fifo, head, tail)
Trace FIFO Queue put list exit.

Parameters

- fifo – FIFO object
- head – First ll-node
- tail – Last ll-node

sys_port_trace_k_fifo_alloc_put_slist_enter(fifo, list)
Trace FIFO Queue put slist entry.

Parameters

- **fifo** – FIFO object
- **list** – Syslist object

sys_port_trace_k_fifo_alloc_put_slist_exit(fifo, list)
Trace FIFO Queue put slist exit.

Parameters

- **fifo** – FIFO object
- **list** – Syslist object

sys_port_trace_k_fifo_get_enter(fifo, timeout)
Trace FIFO Queue get entry.

Parameters

- **fifo** – FIFO object
- **timeout** – Timeout period

sys_port_trace_k_fifo_get_exit(fifo, timeout, ret)
Trace FIFO Queue get exit.

Parameters

- **fifo** – FIFO object
- **timeout** – Timeout period
- **ret** – Return value

sys_port_trace_k_fifo_peek_head_enter(fifo)
Trace FIFO Queue peek head entry.

Parameters

- **fifo** – FIFO object

sys_port_trace_k_fifo_peek_head_exit(fifo, ret)
Trace FIFO Queue peek head exit.

Parameters

- **fifo** – FIFO object
- **ret** – Return value

sys_port_trace_k_fifo_peek_tail_enter(fifo)
Trace FIFO Queue peek tail entry.

Parameters

- **fifo** – FIFO object

sys_port_trace_k_fifo_peek_tail_exit(fifo, ret)
Trace FIFO Queue peek tail exit.

Parameters

- **fifo** – FIFO object
- **ret** – Return value

LIFO

group subsys_tracing_apis_lifo
LIFO Tracing APIs.

Defines

sys_port_trace_k_lifo_init_enter(lifo)
Trace initialization of LIFO Queue entry.

Parameters

- lifo – LIFO object

sys_port_trace_k_lifo_init_exit(lifo)
Trace initialization of LIFO Queue exit.

Parameters

- lifo – LIFO object

sys_port_trace_k_lifo_put_enter(lifo, data)
Trace LIFO Queue put entry.

Parameters

- lifo – LIFO object
- data – Data item

sys_port_trace_k_lifo_put_exit(lifo, data)
Trace LIFO Queue put exit.

Parameters

- lifo – LIFO object
- data – Data item

sys_port_trace_k_lifo_alloc_put_enter(lifo, data)
Trace LIFO Queue alloc put entry.

Parameters

- lifo – LIFO object
- data – Data item

sys_port_trace_k_lifo_alloc_put_exit(lifo, data, ret)
Trace LIFO Queue alloc put exit.

Parameters

- lifo – LIFO object
- data – Data item
- ret – Return value

sys_port_trace_k_lifo_get_enter(lifo, timeout)
Trace LIFO Queue get entry.

Parameters

- lifo – LIFO object
- timeout – Timeout period

sys_port_trace_k_lifo_get_exit(lifo, timeout, ret)
Trace LIFO Queue get exit.

Parameters

- lifo – LIFO object
- timeout – Timeout period

- **ret** – Return value

Stacks

group subsys_tracing_apis_stack

Stack Tracing APIs.

Defines

sys_port_trace_k_stack_init(stack)

Trace initialization of Stack.

Parameters

- **stack** – Stack object

sys_port_trace_k_stack_alloc_init_enter(stack)

Trace Stack alloc init attempt entry.

Parameters

- **stack** – Stack object

sys_port_trace_k_stack_alloc_init_exit(stack, ret)

Trace Stack alloc init outcome.

Parameters

- **stack** – Stack object
- **ret** – Return value

sys_port_trace_k_stack_cleanup_enter(stack)

Trace Stack cleanup attempt entry.

Parameters

- **stack** – Stack object

sys_port_trace_k_stack_cleanup_exit(stack, ret)

Trace Stack cleanup outcome.

Parameters

- **stack** – Stack object
- **ret** – Return value

sys_port_trace_k_stack_push_enter(stack)

Trace Stack push attempt entry.

Parameters

- **stack** – Stack object

sys_port_trace_k_stack_push_exit(stack, ret)

Trace Stack push attempt outcome.

Parameters

- **stack** – Stack object
- **ret** – Return value

`sys_port_trace_k_stack_pop_enter`(stack, timeout)
Trace Stack pop attempt entry.

Parameters

- `stack` – Stack object
- `timeout` – Timeout period

`sys_port_trace_k_stack_pop_blocking`(stack, timeout)
Trace Stack pop attempt blocking.

Parameters

- `stack` – Stack object
- `timeout` – Timeout period

`sys_port_trace_k_stack_pop_exit`(stack, timeout, ret)
Trace Stack pop attempt outcome.

Parameters

- `stack` – Stack object
- `timeout` – Timeout period
- `ret` – Return value

Message Queues

group `subsys_tracing_apis_msgq`
Message Queue Tracing APIs.

Defines

`sys_port_trace_k_msgq_init`(msgq)
Trace initialization of Message Queue.

Parameters

- `msgq` – Message Queue object

`sys_port_trace_k_msgq_alloc_init_enter`(msgq)
Trace Message Queue alloc init attempt entry.

Parameters

- `msgq` – Message Queue object

`sys_port_trace_k_msgq_alloc_init_exit`(msgq, ret)
Trace Message Queue alloc init attempt outcome.

Parameters

- `msgq` – Message Queue object
- `ret` – Return value

`sys_port_trace_k_msgq_cleanup_enter`(msgq)
Trace Message Queue cleanup attempt entry.

Parameters

- `msgq` – Message Queue object

`sys_port_trace_k_msgq_cleanup_exit`(msgq, ret)
Trace Message Queue cleanup attempt outcome.

Parameters

- `msgq` – Message Queue object
- `ret` – Return value

`sys_port_trace_k_msgq_put_enter`(msgq, timeout)
Trace Message Queue put attempt entry.

Parameters

- `msgq` – Message Queue object
- `timeout` – Timeout period

`sys_port_trace_k_msgq_put_blocking`(msgq, timeout)
Trace Message Queue put attempt blocking.

Parameters

- `msgq` – Message Queue object
- `timeout` – Timeout period

`sys_port_trace_k_msgq_put_exit`(msgq, timeout, ret)
Trace Message Queue put attempt outcome.

Parameters

- `msgq` – Message Queue object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_msgq_get_enter`(msgq, timeout)
Trace Message Queue get attempt entry.

Parameters

- `msgq` – Message Queue object
- `timeout` – Timeout period

`sys_port_trace_k_msgq_get_blocking`(msgq, timeout)
Trace Message Queue get attempt blockings.

Parameters

- `msgq` – Message Queue object
- `timeout` – Timeout period

`sys_port_trace_k_msgq_get_exit`(msgq, timeout, ret)
Trace Message Queue get attempt outcome.

Parameters

- `msgq` – Message Queue object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_msgq_peek`(msgq, ret)
Trace Message Queue peek.

Parameters

- **msgq** – Message Queue object
- **ret** – Return value

sys_port_trace_k_msgq_purge(msgq)
Trace Message Queue purge.

Parameters

- **msgq** – Message Queue object

Mailbox

group subsys_tracing_apis_mbox
Mailbox Tracing APIs.

Defines

sys_port_trace_k_mbox_init(mbox)
Trace initialization of Mailbox.

Parameters

- **mbox** – Mailbox object

sys_port_trace_k_mbox_message_put_enter(mbox, timeout)
Trace Mailbox message put attempt entry.

Parameters

- **mbox** – Mailbox object
- **timeout** – Timeout period

sys_port_trace_k_mbox_message_put_blocking(mbox, timeout)
Trace Mailbox message put attempt blocking.

Parameters

- **mbox** – Mailbox object
- **timeout** – Timeout period

sys_port_trace_k_mbox_message_put_exit(mbox, timeout, ret)
Trace Mailbox message put attempt outcome.

Parameters

- **mbox** – Mailbox object
- **timeout** – Timeout period
- **ret** – Return value

sys_port_trace_k_mbox_put_enter(mbox, timeout)
Trace Mailbox put attempt entry.

Parameters

- **mbox** – Mailbox object
- **timeout** – Timeout period

`sys_port_trace_k_mbox_put_exit`(mbox, timeout, ret)
Trace Mailbox put attempt blocking.

Parameters

- `mbox` – Mailbox object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mbox_async_put_enter`(mbox, sem)
Trace Mailbox async put entry.

Parameters

- `mbox` – Mailbox object
- `sem` – Semaphore object

`sys_port_trace_k_mbox_async_put_exit`(mbox, sem)
Trace Mailbox async put exit.

Parameters

- `mbox` – Mailbox object
- `sem` – Semaphore object

`sys_port_trace_k_mbox_get_enter`(mbox, timeout)
Trace Mailbox get attempt entry.

Parameters

- `mbox` – Mailbox entry
- `timeout` – Timeout period

`sys_port_trace_k_mbox_get_blocking`(mbox, timeout)
Trace Mailbox get attempt blocking.

Parameters

- `mbox` – Mailbox entry
- `timeout` – Timeout period

`sys_port_trace_k_mbox_get_exit`(mbox, timeout, ret)
Trace Mailbox get attempt outcome.

Parameters

- `mbox` – Mailbox entry
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mbox_data_get`(rx_msg)
Trace Mailbox data get.

rx_msg Receive Message object

Pipes

group `subsys_tracing_apis_pipe`
Pipe Tracing APIs.

Defines

sys_port_trace_k_pipe_init(pipe)
Trace initialization of Pipe.

Parameters

- pipe – Pipe object

sys_port_trace_k_pipe_cleanup_enter(pipe)
Trace Pipe cleanup entry.

Parameters

- pipe – Pipe object

sys_port_trace_k_pipe_cleanup_exit(pipe, ret)
Trace Pipe cleanup exit.

Parameters

- pipe – Pipe object
- ret – Return value

sys_port_trace_k_pipe_alloc_init_enter(pipe)
Trace Pipe alloc init entry.

Parameters

- pipe – Pipe object

sys_port_trace_k_pipe_alloc_init_exit(pipe, ret)
Trace Pipe alloc init exit.

Parameters

- pipe – Pipe object
- ret – Return value

sys_port_trace_k_pipe_flush_enter(pipe)
Trace Pipe flush entry.

Parameters

- pipe – Pipe object

sys_port_trace_k_pipe_flush_exit(pipe)
Trace Pipe flush exit.

Parameters

- pipe – Pipe object

sys_port_trace_k_pipe_buffer_flush_enter(pipe)
Trace Pipe buffer flush entry.

Parameters

- pipe – Pipe object

sys_port_trace_k_pipe_buffer_flush_exit(pipe)
Trace Pipe buffer flush exit.

Parameters

- pipe – Pipe object

`sys_port_trace_k_pipe_put_enter`(pipe, timeout)
Trace Pipe put attempt entry.

Parameters

- `pipe` – Pipe object
- `timeout` – Timeout period

`sys_port_trace_k_pipe_put_blocking`(pipe, timeout)
Trace Pipe put attempt blocking.

Parameters

- `pipe` – Pipe object
- `timeout` – Timeout period

`sys_port_trace_k_pipe_put_exit`(pipe, timeout, ret)
Trace Pipe put attempt outcome.

Parameters

- `pipe` – Pipe object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_pipe_get_enter`(pipe, timeout)
Trace Pipe get attempt entry.

Parameters

- `pipe` – Pipe object
- `timeout` – Timeout period

`sys_port_trace_k_pipe_get_blocking`(pipe, timeout)
Trace Pipe get attempt blocking.

Parameters

- `pipe` – Pipe object
- `timeout` – Timeout period

`sys_port_trace_k_pipe_get_exit`(pipe, timeout, ret)
Trace Pipe get attempt outcome.

Parameters

- `pipe` – Pipe object
- `timeout` – Timeout period
- `ret` – Return value

Heaps

group `subsys_tracing_apis_heap`
Heap Tracing APIs.

Defines

sys_port_trace_k_heap_init(h)
Trace initialization of Heap.

Parameters

- h – Heap object

sys_port_trace_k_heap_aligned_alloc_enter(h, timeout)
Trace Heap aligned alloc attempt entry.

Parameters

- h – Heap object
- timeout – Timeout period

sys_port_trace_k_heap_aligned_alloc_blocking(h, timeout)
Trace Heap align alloc attempt blocking.

Parameters

- h – Heap object
- timeout – Timeout period

sys_port_trace_k_heap_aligned_alloc_exit(h, timeout, ret)
Trace Heap align alloc attempt outcome.

Parameters

- h – Heap object
- timeout – Timeout period
- ret – Return value

sys_port_trace_k_heap_alloc_enter(h, timeout)
Trace Heap alloc enter.

Parameters

- h – Heap object
- timeout – Timeout period

sys_port_trace_k_heap_alloc_exit(h, timeout, ret)
Trace Heap alloc exit.

Parameters

- h – Heap object
- timeout – Timeout period
- ret – Return value

sys_port_trace_k_heap_free(h)
Trace Heap free.

Parameters

- h – Heap object

sys_port_trace_k_heap_realloc_enter(h, ptr, bytes, timeout)
Trace Heap realloc enter.

Parameters

- h – Heap object

- **ptr** – Pointer to reallocate
- **bytes** – Bytes to reallocate
- **timeout** – Timeout period

sys_port_trace_k_heap_realloc_exit(h, ptr, bytes, timeout, ret)
Trace Heap realloc exit.

Parameters

- **h** – Heap object
- **ptr** – Pointer to reallocate
- **bytes** – Bytes to reallocate
- **timeout** – Timeout period
- **ret** – Return value

sys_port_trace_k_heap_sys_k_aligned_alloc_enter(heap)
Trace System Heap aligned alloc enter.

Parameters

- **heap** – Heap object

sys_port_trace_k_heap_sys_k_aligned_alloc_exit(heap, ret)
Trace System Heap aligned alloc exit.

Parameters

- **heap** – Heap object
- **ret** – Return value

sys_port_trace_k_heap_sys_k_malloc_enter(heap)
Trace System Heap aligned alloc enter.

Parameters

- **heap** – Heap object

sys_port_trace_k_heap_sys_k_malloc_exit(heap, ret)
Trace System Heap aligned alloc exit.

Parameters

- **heap** – Heap object
- **ret** – Return value

sys_port_trace_k_heap_sys_k_free_enter(heap, heap_ref)
Trace System Heap free entry.

Parameters

- **heap** – Heap object
- **heap_ref** – Heap reference

sys_port_trace_k_heap_sys_k_free_exit(heap, heap_ref)
Trace System Heap free exit.

Parameters

- **heap** – Heap object
- **heap_ref** – Heap reference

`sys_port_trace_k_heap_sys_k_calloc_enter`(heap)
Trace System heap calloc enter.

Parameters

- `heap`

`sys_port_trace_k_heap_sys_k_calloc_exit`(heap, ret)
Trace System heap calloc exit.

Parameters

- `heap` – Heap object
- `ret` – Return value

`sys_port_trace_k_heap_sys_k_realloc_enter`(heap, ptr)
Trace System heap realloc enter.

Parameters

- `heap`
- `ptr`

`sys_port_trace_k_heap_sys_k_realloc_exit`(heap, ptr, ret)
Trace System heap realloc exit.

Parameters

- `heap` – Heap object
- `ptr` – Memory pointer
- `ret` – Return value

Memory Slabs

group `subsys_tracing_apis_mslab`
Memory Slab Tracing APIs.

Defines

`sys_port_trace_k_mem_slab_init`(slab, rc)
Trace initialization of Memory Slab.

Parameters

- `slab` – Memory Slab object
- `rc` – Return value

`sys_port_trace_k_mem_slab_alloc_enter`(slab, timeout)
Trace Memory Slab alloc attempt entry.

Parameters

- `slab` – Memory Slab object
- `timeout` – Timeout period

`sys_port_trace_k_mem_slab_alloc_blocking`(slab, timeout)
Trace Memory Slab alloc attempt blocking.

Parameters

- `slab` – Memory Slab object
- `timeout` – Timeout period

`sys_port_trace_k_mem_slab_alloc_exit`(slab, timeout, ret)
Trace Memory Slab alloc attempt outcome.

Parameters

- `slab` – Memory Slab object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mem_slab_free_enter`(slab)
Trace Memory Slab free entry.

Parameters

- `slab` – Memory Slab object

`sys_port_trace_k_mem_slab_free_exit`(slab)
Trace Memory Slab free exit.

Parameters

- `slab` – Memory Slab object

Timers

group `subsys_tracing_apis_timer`
Timer Tracing APIs.

Defines

`sys_port_trace_k_timer_init`(timer)
Trace initialization of Timer.

Parameters

- `timer` – Timer object

`sys_port_trace_k_timer_start`(timer, duration, period)
Trace Timer start.

Parameters

- `timer` – Timer object
- `duration` – Timer duration
- `period` – Timer period

`sys_port_trace_k_timer_stop`(timer)
Trace Timer stop.

Parameters

- `timer` – Timer object

`sys_port_trace_k_timer_status_sync_enter`(timer)

Trace Timer status sync entry.

Parameters

- `timer` – Timer object

`sys_port_trace_k_timer_status_sync_blocking`(timer, timeout)

Trace Timer Status sync blocking.

Parameters

- `timer` – Timer object
- `timeout` – Timeout period

`sys_port_trace_k_timer_status_sync_exit`(timer, result)

Trace Time Status sync outcome.

Parameters

- `timer` – Timer object
- `result` – Return value

Object tracking

group `subsys_tracing_object_tracking`

Object tracking.

Object tracking provides lists to kernel objects, so their existence and current status can be tracked.

The following global variables are the heads of available lists:

- _track_list_k_timer
- _track_list_k_mem_slab
- _track_list_k_sem
- _track_list_k_mutex
- _track_list_k_stack
- _track_list_k_msgq
- _track_list_k_mbox
- _track_list_k_pipe
- _track_list_k_queue
- _track_list_k_event

Defines

`SYS_PORT_TRACK_NEXT`(list)

Gets node's next element in a object tracking list.

Parameters

- `list` – Node to get next element from.

Syscalls

group `subsys_tracing_apis_syscall`

Syscall Tracing APIs.

Defines

`sys_port_trace_syscall_enter`(id, name, ...)

Trace syscall entry.

Parameters

- `id` – Syscall ID (as defined in the generated syscall_list.h)
- `name` – Syscall name as a token (ex: k_thread_create)
- `...` – Other parameters passed to the syscall

`sys_port_trace_syscall_exit`(id, name, ...)

Trace syscall exit.

Parameters

- `id` – Syscall ID (as defined in the generated syscall_list.h)
- `name` – Syscall name as a token (ex: k_thread_create)
- `...` – Other parameters passed to the syscall, if the syscall has a return, the return value is the last parameter in the list

4.14 Resource Management

There are various situations where it's necessary to coordinate resource use at runtime among multiple clients. These include power rails, clocks, other peripherals, and binary device power management. The complexity of properly managing multiple consumers of a device in a multi-threaded system, especially when transitions may be asynchronous, suggests that a shared implementation is desirable.

Zephyr provides managers for several coordination policies. These managers are embedded into services that use them for specific functions.

- *On-Off Manager*

4.14.1 On-Off Manager

An on-off manager supports an arbitrary number of clients of a service which has a binary state. Example applications are power rails, clocks, and binary device power management.

The manager has the following properties:

- The stable states are off, on, and error. The service always begins in the off state. The service may also be in a transition to a given state.

- The core operations are request (add a dependency) and release (remove a dependency). Supporting operations are reset (to clear an error state) and cancel (to reclaim client data from an in-progress transition). The service manages the state based on calls to functions that initiate these operations.
- The service transitions from off to on when first client request is received.
- The service transitions from on to off when last client release is received.
- Each service configuration provides functions that implement the transition from off to on, from on to off, and optionally from an error state to off. Transitions must be invokable from both thread and interrupt context.
- The request and reset operations are asynchronous using *Asynchronous Notifications*. Both operations may be cancelled, but cancellation has no effect on the in-progress transition.
- Requests to turn on may be queued while a transition to off is in progress: when the service has turned off successfully it will be immediately turned on again (where context allows) and waiting clients notified when the start completes.

Requests are reference counted, but not tracked. That means clients are responsible for recording whether their requests were accepted, and for initiating a release only if they have previously successfully completed a request. Improper use of the API can cause an active client to be shut out, and the manager does not maintain a record of specific clients that have been granted a request.

Failures in executing a transition are recorded and inhibit further requests or releases until the manager is reset. Pending requests are notified (and cancelled) when errors are discovered.

Transition operation completion notifications are provided through *Asynchronous Notifications*.

Clients and other components interested in tracking all service state changes, including when a service begins turning off or enters an error state, can be informed of state transitions by registering a monitor with onoff_monitor_register(). Notification of changes are provided before issuing completion notifications associated with the new state.

Note

A generic API may be implemented by multiple drivers where the common case is asynchronous. The on-off client structure may be an appropriate solution for the generic API. Where drivers that can guarantee synchronous context-independent transitions a driver may use *onoff_sync_service* and its supporting API rather than *onoff_manager*, with only a small reduction in functionality (primarily no support for the monitor API).

group `resource_mgmt_onoff_apis`

Defines

`ONOFF_FLAG_ERROR`

Flag indicating an error state.

Error states are cleared using *onoff_reset()*.

`ONOFF_STATE_MASK`

Mask used to isolate bits defining the service state.

Mask a value with this then test for ONOFF_FLAG_ERROR to determine whether the machine has an unfixed error, or compare against ONOFF_STATE_ON,

ONOFF_STATE_OFF, ONOFF_STATE_TO_ON, ONOFF_STATE_TO_OFF, or ONOFF_STATE_RESETTING.

`ONOFF_STATE_OFF`

Value exposed by ONOFF_STATE_MASK when service is off.

`ONOFF_STATE_ON`

Value exposed by ONOFF_STATE_MASK when service is on.

`ONOFF_STATE_ERROR`
